Results. Elevated levels of neopterin as well as B2M were found in the CSF of three patients with primary HIV-1 infection of whom two were neurologically asymptomatic. The levels of the two substances were significantly higher in the early stages in patients with positive CSF or plasma isolation compared with those of the culture-negative patients or the controls. The concentrations in both CSF and plasma seemed to follow a biphasic curve and increased in parallell with progress of infection with the highest levels in patients with AIDS. There was a strong correlation between the neopterin or B2M concentrations in CSF and plasma.
Conclusion. HIV-1 may elicit a cell-mediated immune response in CNS during the earlier stages of infection without concomitant neurological symptoms. The pathological processes in CNS and blood seem to develop in parallell rather then being restricted to one compartment.

Th.B.P.227 LACK OF RELATIONSHIP BETWEEN TRYPTOPHAN AND NEUROLOGICAL DISEASE IN HIV-1-INFECTED INDIVIDUALS

Brew, Bruce J; Heyes, M; Price, RW. Memorial Sloan-Kettering Cancer Center, New York, NY USA

Objectives: 1) To confirm previous reports of lowered tryptophan levels in the plasma and cerebrospinal fluid (CSF) of HIV-infected patients. 2) To determine any relationship between tryptophan concentrations and AIDS Dementia Complex (ADC) or peripheral neuropathy (PN).
Methods: 46 patients with ADC in the absence of other confounding illnesses, 22 of whom had HIV-related (PN), were assessed by a neurologist and staged as to the functional severity of ADC and PN. A clinical scale of motor impairment was also assigned. Cerebrospinal fluid (CSF) was available in all patients while plasma was available in 42. Tryptophan was measured in these samples by high performance liquid chromatography.
Results: 86% had reduced CSF tryptophan concentrations while 92% had lowered plasma concentrations. There was no significant correlation between the stage of ADC and either plasma or CSF tryptophan. Similarly, there was no relationship with the degree of motor impairment or the presence/severity of PN. As most patients had depressed levels of tryptophan, further analysis was carried out with the upper and lower quartiles of tryptophan concentrations. Again there was no relationship.
Conclusions: Despite the high prevalence and theoretical implications of depressed tryptophan concentrations in both CSF and plasma, it is unlikely that tryptophan is involved in the pathogenesis of ADC or HIV-related PN.

Th.B.P.228 CEREBROSPINAL FLUID FINDINGS IN TWO PATIENTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS

R. Alvarado*, R. Andrade**, M. A. Pacheco**, V. Bartos**, R. de la Vega***, J. Auza***, *San Gabriel Hospital; **Immonology Lab, INLASA, Ministry of Health; ***UMSA School of Medicine, La Paz, Bolivia.

Objective. The study was to determine cerebrospinal fluid changes in two homosexuals infected with HIV. The first one. M. P., got infected in 1983 in San Francisco, U.S.A., and he was the source of infection of his partner, R. F., in 1987, when they were in prison in La Paz. The partner became seroreactive for HIV in May, 1988 (both patients confirmed by Western Blot). The neurological examination revealed that they were lucid, conscious, well-oriented in time and space, and had normal fundoscopic examinations. They did not show any neurological symptomatology. M. P. had a cervical lymphadenopathy.
Methods. The studies were performed in serum and cerebrospinal fluid by the ELISA test (confirmed by Western Blot) and the Delayed Hypersensitivity Skin Test with the following antigens: PPD (tuberculin), SK/SD (strepkinase and streptodornase), tetanic toxoid and candidin and test of lymphocyte subsets T4/T8 (monoclonal antibodies, Coulter) with immunofluorescence microscope.
Results. The Delayed Hypersensitivity Skin Test was negative, the lymphocyte subsets showed the following results:

	Lymphocytes	T_3	T_4	T_8	Index
M. P.	1.800 (29%)	1.110 (61%)	460 (41%)	630 (39%)	0.7
R.F.	2.672 (32%)	1/736 (65%)	1106 (58%)	729 (42%)	1.4

Conclusion. Both patients were infected with the human immunodeficiency virus, both were neurologically asymptomatic and CSF were within normal limits. The first patient (M. P.) even had anti-HIV antibodies in his CSF.

Th.B.P.229 LONGITUDINAL CSF CELL COUNTS AND PROTEIN LEVELS IN 258 HIV-INFECTED US AIR FORCE PERSONNEL

Marshall, Douglas V; Brey, RL; Butzin, CA; Zajac RA; Boswell RN
Wilford Hall USAF Medical Center, Lackland Air Force Base, Texas, USA

Objective. To describe CSF cell counts and protein level changes observed over time in a cohort of 258 individuals infected with HIV-1. Methods. Changes in CSF cells and protein in 258 HIV-infected USAF personnel with sequential CSF studies a minimum of nine months apart were evaluated. Patients with CNS opportunistic infections were excluded. Patients were grouped according to T-helper cell (CD4) counts.
Results.

		Abn (Time 1)	Abn (Time 2)
CD4 > 400	Nuc Cells	86/232 (37.1%)	122/214 (57%)
	Protein	61/232 (26.3%)	37/214 (17.3%)
CD4 < 400	Nuc Cells	10/26 (38.5%)	20/44 (45.5%)
	Protein	6/26 (23.1%)	8/44 (18.2%)

Conclusion. Over time, the percentage of individuals with > 5 cells/cmm increased and the percentage with protein > 45 mg/100 ml decreased regardless of T-helper cell count. No CSF change correlated with neurological function.

Th.B.P.230 INTRATHECAL PRODUCTION OF IgG IN A LONGITUDINAL STUDY OF 258 HIV-INFECTED US AIR FORCE PERSONNEL

Marshall, Douglas V; Brey RL; Butzin CA; Lucey DR; Boswell RN
Wilford Hall USAF Medical Center, Lackland Air Force Base, Texas, USA

Objective. To study changes in CNS immune response and peripheral immune status in HIV-infected USAF personnel over time.
Methods. A cohort of 258 HIV-1 infected USAF personnel with a minimum of 9 months follow-up were evaluated for changes in CSF IgG, IgG synthesis rate (IgG-S), IgG index (IgG-I), oligoclonal bands (OCB), and blood T-helper (CD4) lymphocyte counts. Patients with CNS opportunistic infections were excluded.
Results.

		Abn (Time 1)	Abn (Time 2)
CD4 > 400	CSF IgG	60/222 (27%)	69/213 (32.4%)
	IgG-I	85/221 (38.5%)	115/213 (54.0%)
	IgG-S	67/218 (30.7%)	76/205 (37%)
	OCB	30/216 (13.9%)	45/207 (21.7%)
CD4 < 400	CSF IgG	11/26 (42.3%)	20/44 (45.5%)
	IgG-I	13/25 (52%)	31/44 (70.5%)
	IgG-S	12/25 (48%)	21/43 (48.8%)
	OCB	3/26 (11.5%)	12/39 (30.8%)

Quantitatively, mean increases in IgG, IgG-I, IgG-S were most significant ($p < .005$) in those with CD4 counts > 400 cells/cmm.
Conclusion. Elevated IgG intrathecal production over time is present in the entire cohort. The most significant longitudinal quantitative change (not shown above) was seen in those with CD4 counts > 400 cells/cmm. Cross-sectional data over various CD4 counts show similar trend.

Th.B.P.231 Intrathekal antibody production assayed by recombinant antigens, purified gp120 and RIPA

Th. Weber[1], W. Lüke[2], W. Lüer[1], J. Mous[3], D. Stüber[3], H. Döbeli[3], B. Ruf[4], S. Poser[1], H-D. Pohle[4], K. Felgenhauer[1], G. Hunsmann[3]
[1]Department of Neurology, University of Göttingen, FRG; [2]Department of Virology and Immunology, German Primate Research Center, Göttingen, FRG; Hoffmann-La Roche & Co., Basel, Switzerland; [4]II. Medical Clinic, Rudolf Virchow Hospital, Free University of Berlin, Berlin FRG.

Referring to identical IgG concentrations of a reference serum, antibody production within the CNS can be reliably and reproducibly quantitated (reproducibility ± 8%). By a combination of 5 recombinant antigens intrathekal antibody production could be found in 20% of asymptomatic and LAS/ARC patients who did not show a CSF/serum quotient >1.5 as evidence for intrathekal antibody production by conventional ELISA. The prevalence of antibodies declined by about the same percentage in cerebrospinal fluid and serum from 88% (p17), 95.6% (p24), 84.6% (endonuklease) and 100% (reverse transcriptase) in asymptomatic carriers to 56% (p17), 44.1% (p24), 47.1% (endonuklease) and 83% (reverse transcriptase) for AIDS patients. In all cases antibodies to ENV-80 and gp120 could be demonstrated. The intrathekal immune response decreases faster than the systemic immune response. These findings provide evidence for a faster random loss and /or inactivation of B cell clones in the CNS as compared to the immune system.

Th.B.P.232 QUINOLINIC ACID CONCENTRATIONS ARE INCREASED IN PLASMA AND CEREBROSPINAL FLUID IN AIDS AND CORRLEATES WITH AIDS DEMENTIA COMPLEX

M.P. Heyes[*], B.J. Brew[**], S.P. Markey[*], A. Martin[***], R.W. Price[**], D. Rubinow[*] and A.M. Salazar[***].
National Institute of Mental Health[*], Bethesda, MD; Memorial Sloane Kettering Cancer Center, NY[**]; Walter Reed AMC[***], Washington DC, U.S.A.

AIDS patients may develop dementia, motor and psychiatric disturbances and at post mortem exhibit brain atrophy, white matter pallor and infiltrates of multinucleated giant cells. We have found increased concentrations of he endogenous neurotoxin and convulsant quinolinic acid (QUIN, an intermediary tryptophan metabolite) in plasma and brain of mice treated with pokeweed mitogen (J. Neurochem. (1988) 51, 1946). Conceivably, if QUIN increases in the brains of AIDS patients, QUIN could contribute to neurologic abnormalities in AIDS.
Objective: To investigate whether brain and plasma QUIN content is increased in AIDS.
Methods: QUIN was measured by gas chromatography/mass spectrometry using [^{18}O]-QUIN as internal standard in cerebrospinal fluid (CSF) and plasma of nine normal volunteers, 23 patients in the early stages of HIV infection (Walter Reed scale 1-2) and 114 AIDS patients.
Results: In controls, CSF QUIN was 18.4±3.4 nmol/L and plasma QUIN was 437±66 nmol/L, values typical for our laboratory. In AIDS, CSF QUIN was 644.6±150.7 nmol/L; $p<0.00001$ as logarithm): 4% of patients had CSF QUIN values > 1μmol/L, concentrations toxic to neurons *in vitro*. Plasma QUIN increased to 1465±150 nmol/L ($p<0.001$). CSF QUIN concentrations were above 50 nmol/L in 30% of patients in earlier stages of AIDS. In demented patients without compounding illness, significant correlations were found between log CSFQUIN and: AIDS dementia complex stage ($p<0.001$), CSF Beta 2 ($p<0.005$), serum beta 2 ($p<0.005$) and log plasma QUIN ($p<0.00001$). Log CSF QUIN was not correlated with albumin CSF/plasma ratio indicating increased CSF QUIN probably did not originate in blood.
Conclusions: Increased CSF and plasma QUIN are consistent with increased L-tryptophan catabolism through the kynurenine pathway. Increased QUIN may contribute to the neurologic abnormalities of AIDS.

Th.B.P.233 CSF β_2MICROGLOBULIN AS A MARKER OF THE PRESENCE AND SEVERITY OF AIDS DEMENTIA COMPLEX

Brew, Bruce J; Bhalla, R; Paul, M; Schwartz, M; Price, RW.
Memorial Sloan-Kettering Cancer Center, New York, NY USA

Objectives: 1) To assess the utility of cerebrospinal fluid (CSF) β_2 microglobulin (β_2M) as a marker of the presence and severity of AIDS Dementia Complex (ADC), 2) To compare β_2M to other CSF markers and 3) To determine its concentration in response to azidothymidine (AZT) therapy.
Methods: Of 155 paired samples of CSF and serum, 69 were from patients who had ADC without any confounding illness. 8 patients had samples taken before starting AZT and later while on AZT. All patients had been assessed by a neurologist and staged according to the severity of ADC. β_2M was measured in both CSF and serum by radioimmunoassay (Pharmacia, Sweden). Other CSF markers of ADC that were measured included HIV-1 p24, and neopterin. The ratio of CSF-to-serum albumin was used as an index of the integrity of the blood-brain barrier.
Results: In those patients with only ADC, there was a strong correlation between the concentration of CSF β_2M and ADC stage ($p<0.001$). The elevation was independent of blood-brain barrier damage and unrelated to CSF white cell count and serum β_2M. Compared to the other CSF markers, β_2M was the most useful, while HIV p24 was the least sensitive. In 7 of the 8 AZT-treated patients with serial samples, CSF β_2M concentration fell, sometimes to normal.
Conclusions: CSF β_2M is a sensitive but non-specific surrogate marker of the presence and severity of ADC. Additionally, it may be useful in monitoring therapeutic response.

Th.B.P.234 ADENOSINE DEAMINASE (ADA) VALUES IN CEREBROSPINAL FLUID OF ASYMPTOMATIC HIV INFECTED PATIENTS

B.Clotet,G.Sirera,C.Pastor,J.Romeu,C.Tural,A.Jou,M.Foz.
Infectious Diseases Unit.Hospital de Badalona "Germans Trias i Pujol" Badalona.Barcelona.Catalonia.Spain

Objective:To determine the normal values for ADA in CSF of HIV seropositive patients.Material:30 asymptomatic patients(20 males and 10 females);27 were intravenous drug abusers(IDAs);2 homosexuals and 1 had frequent contacts with prostitutes.Patients belonged to stage III and IV-C2.Antibodies to HIV were measured by two different ELISA methods.The CSF absorbance reading was scored positive if it was more than $\bar{X}$+2 S.D.($\bar{X}$ is the average absorption of 12 normal HIV negative CSF controls).ADA activity was evaluated as described previously (J Infect Dis 1987;155:603-7).Results:All CSF examined had normal protein and cell count.All patients had ADA values below 4 U/L.A table showing all results would be presented.Discussion:ADA activity is increased in meningeal tuberculosis (MT).Since MT in patients at risk for AIDS may be frequent in some areas of the world it is of interest to determine the normal values in such patients. It is also important to avoid false negative or false positive results in the diagnosis of MT.The presence of HIV antibodies in CSF does not alter the ADA determination.Silent CNS infection (as suggested by the presence in CSF of HIV antibodies) does not imply a change in base-line values for ADA.When MT is suspected, ADA assessment if elevated may give a rapid clue for initiating specific treatment.

Th.B.P.235 DETECTION OF HIV MARKERS IN CEREBROSPINAL FLUID

Agut, Henri*; Devillechabrolle, A.*; Katlama, C.**; Dunsten, P.**; Schuller, E.***; Huraux, J.M.* et al.

*Laboratoire de Bactériologie-Virologie, Hôpital de la Pitié-Salpêtrière, Paris, France, **Département de Médecine tropicale, Parasitologie et Santé Publique, Hôpital de la Pitié-Salpêtrière, Paris, France, ***INSERM U134, Paris, France.

Objective. To analyse the contribution of virological study of CSF to the diagnosis and monitoring of neurological HIV infections.
Methods. HIV markers were studied in CSF specimens and paired blood samples from patients involved in a prospective cohort study. Many of these patients were treated with zidovudine. HIV antigen and specific antibodies were tested by conventional enzyme-linked immunoassays (EIA). Virus culture was performed with PHA-stimulated peripheral blood mononuclear cells; HIV was detected in culture by reverse transcriptase assay, HIV antigen EIA and specific proviral DNA amplification using PCR.
Results. In a preliminary analysis of 40 CSF specimens, HIV was recovered from only 8 samples (20%) whereas it was recovered from 24 out of 33 paired blood samples (72%). HIV antigen was detected in 8 CSF specimens of which 4 were culture-positive. HIV recovery in CSF was more frequent in the case of AIDS patients (41%) then in other stages of HIV infection (5%); virus recovery was observed in patients without neurological symptoms or in association with opportunistic infections and neoplasms of the CNS as well as in putative HIV encephalitis. In a partial study (23 CSF specimens), all samples were found to have HIV antibodies, most of them exhibiting high titers with evidence of intense intrathecal synthesis and no apparent correlation with HIV recovery. The characterization of HIV antibodies in CSF is in progress.
Conclusion. The specificity of CSF HIV markers seems to be poor for the diagnosis of HIV-related diseases of CNS, specially during zidovudine treatment, but this point deserves further investigations.

Th.B.P.236

Cerebrospinal Fluid and Blood markers in HIV seropositive individuals with and without Neurologic Complications. E. J. Singer, M.D*., K. Syndulko, Ph.D*., P. Rosen, M.D., R. Mitsuyasu, M.D**., B. Chandra, B.S., L. Resnick, M.D.***, P. Shapshak, Ph.D.***, Wallace W. Tourtellotte, M.D., Ph.D* Neurology Service, VAMC W. Los Angeles, CA 90073, Depts. of **Medicine and *Neurology, UCLA School of Medicine. 213 824-4307, and the ***Depts of Dermatology and Pathology, University of Miami, Miami, FL, U.S.A.
Objective:: See title. Method: 137 HIV seropositive individuals without central nervous system (CNS) opportunistic infections or neoplasms were entered into a longitudinal study; 67 were classified as systemically (with or without neurologic dysfunction) asymptomatic (ASP), 60 as ARC, and 10 as AIDS. 102 of the subjects had one or more CSF exams. Results: 25% of ASPs, 71% of ARCs and 100% of AIDS were found to have HIV related neurologic disease. 14% of ASPs, 56% of ARC, and 38% of AIDS had clinically evaluated cognitive disorders (dementia - p ≤ 0.0001), whereas 6 % of ASPs, 21% of ARC and 75% of AIDS had CNS motor signs (p ≤ 0.0001). Intra-blood-brain-barrier (I-BBB) IgG synthesis rate was abnormal in 88% of ASPs, 91% of ARCs and 66% of AIDS. I-BBB IgG synthesis rate significantly elevated (p ≤ 0.003) in neuropositives versus neuronegatives, 29 mg/day vs. 11 respectively. However, there were no significant differences in other CSF values (mean CSF IgG bands compared to serum, white blood cell counts, I-BBB albumin leakage, HIV isolation and p24 antigen levels) between neuropositives and neuronegatives. In contrast, blood markers of immune deficiency (T4 cell counts, T4:T8 ratio, and p24 antigen levels) were significantly worse in neuropositives versus neuronegatives. Significantly higher CSF p24 antigen levels were found in subjects with CNS motor signs (p<0.01) versus those without motor signs and a similar trend was found in demented versus non-demented subjects (p = 0.08). A subset of the most demented patients (n=8) showed a significant (p<.0.0001) elevation of p24 antigen compared to those with no or mild dementia (49pg/ml versus 5pg/ml, respectively). Subjects with CNS motor signs also had significantly more pleocytosis (p ≤ 0.003) than those without (8 WBC/cmm vs. 2, respectively). Warranted Conclusions: HIV seropositive individuals with HIV related neurologic problems, especially CNS motor signs and/or moderate to severe dementia, tended to have lower systemic immune competence (T4) and higher p24 in the serum than subjects who did not; on the other hand, we found individuals who had low immune competence and were neurologically normal. Additionally, those individuals with neuroproblems especially due to CNS motor dysfunction and/or moderate to severe dementia, also had more pleocytosis and higher intra-BBB IgG synthesis rate, evidence that there was a more intense inflammatory reaction in the CNS nervous system. This is concordant with increased viral expression.as manifested by the higher p24 concentration in the CNS.

Th.B.P.237 SEROTONIN METABOLITE DEFICIENCY IN HIV INFECTION AND AIDS

Britton, Carolyn B.; Kranzler, S.; Naini, A.; Coté,L.
HIV CENTER, Columbia University Collete of Physicians and Surgeons, New York, New York, U.S.A.

Objective: To determine if cerebrospinal fluid biogenic amine metabolites are altered in patients with HIV infection or AIDS.
Methods: Biogenic amine metabolites were analyzed in seventeen cerebrospinal fluid specimens from fifteen patients with HIV infection or AIDS using high performance liquid chromatography.
Results: Levels of the serotonin metabolite, 5-hydroxyindoleacetic acid (5-HIAA), were profoundly reduced in 13 samples from 11 patients: range 3.8-17.1 ng/ml; mean 10.1 ng/ml; normal ≥30ng/ml = 33% normal level. Homovanillic acid levels (HVA, a metabolite of dopamine) were variably affected: range 9.4-59 ng/ml; mean 22.9 ng/ml; normal ≥30 ng/ml = 76% normal. In four patients, both 5-HIAA and HVA levels were borderline or normal. Four of the eleven patients with reduced 5-HIAA levels had only presumed HIV-related dementia and/or myelopathy and the others: other cerebral infections-3; thoracic zoster-1; stroke-1; cauda equina syndrome-1; syncope-1. One of the four patients with borderline or normal results was treated with phenytoin, a drug reported to increase serotonin synthesis in brain, while one each had toxoplasmosis, pulmonary TBC, unknown HIV status with risk.
Conclusions: The data suggest an early, possibly selective, inhibitory effect of HIV infection on serotonin synthesis. Although HIV is not detected in neuronal cell populations, the presence of the virus in brain may cause alterations in neuronal cellular metabolism and neurotransmitter synthesis that result in the cerebral and spinal cord syndromes attributed to the virus.

Th.B.P.238 INCREASING CSF ABNORMALITIES IN HIV-1 INFECTED INDIVIDUALS WITH DECLINING SYSTEMIC IMMUNE STATUS

McArthur, Justin C., McArthur, J.H.; Herman, C.; Farzadegan, H.; Margolick, J.; Saah, A., Johns Hopkins Medical Institutions, Baltimore, MD USA

Objective: To correlate changes in cerebrospinal fluid (CSF) profiles with neurological status and peripheral blood CD4 lymphocyte count within a prospective neurological study (Multicenter AIDS Cohort Study).
Methods: 25 homosexual/bisexual men underwent at least 2 lumbar punctures (LP) at annual intervals, along with standardized neurological and neuropsychological testing, and flow cytometric measurement of CD4 counts. CSF analysis included cell count (WBC), total protein, oligoclonal bands (OCB), immunoglobulin concentration (IgG%), blood-brain-barrier integrity (BBB), and HIV-1 isolation. At the time of the first LP, all subjects were in CDC Groups II or III and none was taking azidothymidine. None had CNS opportunistic infections, neurosyphilis or HIV-1 related neurological disorders at either of the LP's. Subjects were stratified into those with declining blood CD4 counts (≥ 15% decrement) and those with stable CD4 counts (<15% decrement). Changes in the CSF parameters for each individual were summed to provide a net increase or decrease in CNS abnormalities.
Results:

		Change in CSF parameters from LP #1 to LP #2					
	Change in CD4 count	WBC $\geq +2\ mm^3$	Protein ≥ +5 mg/dl	OCB ≥ +1	IgG% ≥0.6	BBB ≥0.6	Culture →+
Decline CD4 (n=20)	$-302/mm^3$	9/20	8/20	7/20	10/20	5/20	1/12
Stable CD4 (n=5)	$+220/mm^3$	3/5	2/5	1/5	1/5	0/5	0/4

Eleven of 20 (55%) with declining CD4 counts showed a net increase in CSF abnormalities compared to 1/5 (20%) with stable CD4 counts. Rising IgG and increasing pleocytosis were the most common changes observed.
Conclusion: Declining systemic immune status was associated with increasing CSF abnormalities, possibly reflecting increased HIV-1 activation within the CNS. Longitudinal study in a larger group will determine whether any of these CSF changes are predictive of overt neurological involvement.

Th.B.P.239 ANTIBODY DEPENDENT CELLULAR CYTOTOXICITY (ADCC) IN BLOOD AND CEREBROSPINAL FLUID (CSF) OF HIV-1 INFECTED ZAIRIAN PATIENTS.

Brown Christopher, Perriens J., Lubaki N., Fauci A., Quinn T., Projet SIDA, Kinshasa, Zaire, National Institutes of Health, Bethesda, Md., Johns Hopkins Hospital, Baltimore, Md, U.S.A.

Objective. To determine whether HIV-1 specific ADCC is found in the CSF of HIV-1 infected patients, and, if so, to examine its relationship to early (N+), late (N++) or absence (N-) of neurologic (CNS) symptoms.
Methods. We collected blood and CSF from 41 hospitalized HIV-1 infected individuals. ADCC activity was determined in a 4 hour chromium 51 release assay, using HIV-1 infected (A5) and uninfected (SUP-T1) tumor cell lines as targets.
Results. In 25 patients studied to date, ADCC activity (expressed as percent CR release) was seen in 92% of blood and 84% of CSF samples. No significant difference was seen between blood and CSF ADCC release (Pearson's correlation coefficient 0.4291 P<O.38). However, one patient had a 27% ADCC reaction in the blood and no detectable CSF ADCC. Another had 29% ADCC release in the CSF and no detectable blood ADCC. Mean ADCC levels (percent chromium release) in clinical groups were as follows:

Group	AIDS +	AIDS-	DEAD	ALIVE	N-	N+	N++
BLD ADCC	21%	31%	28%	27%	29%	26%	28%
CSF ADCC	20%	30%	25%	27%	31%	21%	17%

Conclusion. A decrease in CSF but not blood ADCC was seen in patients with progressive neurologic disease suggesting that CSF ADCC may play an important role in the HIV-1 specific immune response in the central nervous system.

Th.B.P.240 IMMUNOPHENOTYPING IN ASYMPTOMATIC AND NEUROLOGICALLY SYMPTOMATIC ANTI-HIV-1 POSITIVE, ANTI-HTLV-1 NEGATIVE MEN

Klimas, Nancy* **, Berger, J.**, LaVoie, L.** and Fletcher, M.* **, *VA Medical Center and **University of Miami, Miami, FL USA.

Objective To compare distribution of lymphocyte subsets in asymptomatic and neurologically symptomatic men with HIV-1 infection, with each other and with matched controls.
Methods As part of a study of the neurologic aspects of HIV-1 infection, 81 asymptomatic anti-HIV-1 (+) men, 18 anti-HIV-1 (+) men with neurologic symptoms and 18 anti-HIV-1 (-) male risk factor and age matched controls were enrolled in a longitudinal study. All were anti-HTLV-1 negative. Baseline assessments were obtained for lymphocyte subsets by 2 color flow cytometric analysis using 7 pairs of monoclonal antibodies.
Results Significant differences, either between the anti-HIV (+) groups and controls* or between the symptomatic and asymptomatic groups**, were detected in all pairs, except for total T (T1) and total B (B1).

	T4+●	2H4+T4+●	4B4+T4+●	T8+●	I2+T8+●	Ta1+T11+●	NKH.1+●
controls	913	428	595	642	114	546	354
asympt.	533*	235*	311*	939*	341*	331*	257*
sympt.	431* **	155* **	332*	864*	322*	325*	222*

Conclusions Compared to controls, anti-HIV-1 (+) men had significantly lower numbers of T4 cells and 2 subsets of T4, T11 cells expressing the Ta1 activation marker, and cells with the natural killer cell marker, NKH.1. Compared to asymptomatics, subjects with neurologic symptoms had significantly lower numbers of T4 cells, apparently due to a selective loss of 2H4+T4+ lymphocytes, the inducer subset responsible for activating suppressor/cytotoxic T cells. This abnormality may predispose the HIV-1 infected individual to neurologic abnormalities. (Supp. by 1 PO1-NS-25569)

Th.B.P.241 CRF, β-ENDORPHIN AND ACTH ARE SIGNIFICANTLY DECREASED IN CEREBROSPINAL FLUID OF AIDS PATIENTS

Rougeot, Catherine ; Lebas, J.* ; Sobel, A.** ; Everaere, S. and Dray, F.
INSERM et Institut Pasteur, 75724 Paris, France ; *Hôpital Saint-Antoine, Paris, France ; **CHU Henri Mondor, Créteil, France.

Neurologic disorders are often associated with alterations of the immune system in the acquired immunodeficiency syndrome (AIDS). As there is a two-way communication between the neuroendocrine and immune systems, it appears important to evaluate the level of neuropeptide secretions in AIDS patients. Cerebrospinal fluid (CSF) was preferred to peripheral blood, because neuropeptides from CSF provide a more representative picture of cerebral metabolism. CSF from 16 AIDS patients and 10 healthy subjects were radioimmunoassayed for up to 7 peptides after acidic extraction. The results were expressed as mean ± sem (pg/ml) and showed AIDS patients to have : 1 - a significant decrease in corticotropin releasing factor (CRF) 31±7, n=17, (control 76±19, n=10) p<0.05, for β-endorphin 52±5, n=20, (control 79±7, n=11) p<0.05 and for ACTH 16±5, n=13, (control 10±4, n=11) p<0.05. 2 - no significant difference for somatostatin 12±5, n=13, vs 10±4, n=11, p>0.05 and no difference in vasoactive intestinal peptide, substance P and growth releasing factor. The small number of samples (2-7) precluded statistical analysis of the last 3 peptides. 3 - CSF samples were obtained from 3 patients, first at the seropositive stage, and later when AIDS was fully developed ; there was a significant decrease in CRF : 94±16 to 33±12 (p<0.05). In conclusion, a dramatic decline in CRF (60%) and discrete but significant decreases in β-endorphin (44%) and ACTH (39%) were found in the CSF of AIDS patients. Further studies are required to correlate these abnormalities with the HIV infestation.

Th.B.P.242 BRAIN RADIOLOGICAL, NEUROLOGICAL AND NEUROPSYCHOLOGICAL FOLLOW-UP IN RELATION TO INTRATHECAL IMMUNE RESPONSE IN HIV INFECTION

Elovaara, Irina[1,2], Poutiainen, E.,[3] Raininko,R.,[4] Valanne, L.,[5] Virta, A.[5] and Lähdevirta, J.[2] [1]Department of Virology, [3]Neurology, [4]Radiology, University of Helsinki, [2]Aurora Hospital and Kivelä Hospital[5], Helsinki, Finland.

Objective. To evaluate brain CT and/or MRI findings in relation to neurological and cognitive dysfunctions and to intrathecal humoral immune response. Methods. 35 HIV-infected patients (21 at early infection, 14 at late infection) were followed up mostly for 3 years with repeated brain radiological, neurological, neuropsychological examinations and CSF and sera immunological analyses. Results. 49% of the patients had atrophic changes at an initial examination. Patients with cognitive dysfunction, late infection, increased intrathecal HIV-antibody synthesis, and decreased B-cell response had the most severe and most frequent atrophic changes including ventricular enlargement, cerebellar atrophy, cortical atrophy, brain stem atrophy and parenchymal lesions. At he final examination the radiological abnormalities were seen in 75% of the patients. 26% of them developed atrophic changes during the follow-up; further increase in severity of the changes was found in 29% of the cases, while in 20% of the subjects initial abnormality remained unchanged. In most cases the appearance/progression of radiological changes was associated with further deterioration of cognitive functions. When re-examined, of CSF changes only intrathecal HIV-antibody synthesis persisted in most patients, while local CNS IgG synthesis along with CSF pleocytosis were found less frequently. Conclusion. Our results show that with the progression of HIV infection, as intrathecal B-cell response decreases, brain MRI and CT abnormalities together with cognitive dysfunction and CNS HIV-antibody synthesis increase.

Th.B.P.243 CSF CHANGES IN DIFFERENT STAGES OF HIV INFECTION

Minoli, Lorenzo*; Brustia, R.*; Maserati, R.*; Furione, M.*; Franciotta,D.**; Melzi d'Eril, G.L.**.
*Infectious Disease Dept., IRCCS Policlinico San Matteo - University of Pavia.
** IRCCS C. Mondino - University of Pavia, 27100 Pavia, Italy.

To study CSF changes in different stages of HIV infection we evaluated CSFs and sera from 54 consecutive pts., either in asymptomatic, PGL/ARC or full-blown AIDS conditions. AIDS pts. were furtherly subdivided in subjects with: (A) CNS opportunistic infections -OI-; (B) extra-CNS OI and/or neoplasms; (C) CNS changes currently related to a direct HIV action. Specimens were examined for chemistry and microbiological findings, blood-brain barrier damage (BBBD) and intrathecal antibody syntesis (IAS) indexes and for the presence of oligoclonal bands and anti-HIV specific antibodies in the CSF. Results are displayed here below:

stage / test	asymptomatic	PGL/ARC	AIDS (A)	AIDS (B)	AIDS (C)
BBBD	none	1/12	6/16	3/14	2/9
IAS	3/3	4/12	4/16	4/14	2/9
BBBD + IAS	none	none	4/16	1/14	3/9
CSF anti-p24	1/1	6/12	3/13	4/13	4/6

In our series IAS was detected in the 100% of asymtomatic individual and in 22.2 to 33.3% in other groups, indicating an early retroviral infection even in neurologically silent pts. No statistically significant difference was present in AIDS subgroups for CNS indexes that could have been considered useful in differentiating HIV related injuries from CNS HIV-caused OI.

Th.B.P.244 NEOPTERIN AND β_2-MICROGLOBULIN IN CEREBROSPINAL FLUID IN HIV-INFECTION

Goebel, Frank-D.+, Bogner, J.R.+, Junge-Hülsing, B.+, Matuschke, A.+, Heinrich, B.+, Einhäupl, K.*: +Med Poliklinik, *Neurologische Klinik, Universität München, FRG

OBJECTIVE: To assess the value of Neopterin (Npt) and β_2-Microglobulin (β_2-MG) in cerebrospinal fluid (CSF) as parameters of pathological processes in the central nervous system (CNS).
METHODS: Npt, β_2-MG, cell count, protein, albumin and IgG were determined in paired samples of blood and CSF in 95 HIV infected patients (WR1-WR6) and 17 controls.
RESULTS: Taking into account elevated serum values and blood-brain-barrier dysfunction (BBBD) (ratio albumin CSF/serum) a significant correlation was found in the CSF between Npt - protein (p<0.05), Npt - cell count (WR1-4: p<0.001 in contrast to WR5+6: p>0.10) and β_2-MG - protein (p<0.01). BBBD correlated with CSF Npt (p<0.05), but with β_2-MG only in early stages (p<0.001). In 17/19 patients with a ratio Npt CSF/serum >1.0 and in 8/9 patients with a ratio β_2-MG CSF/serum >1.0 severe HIV-encephalopathy, opportunistic infection or lymphoma in the CNS was diagnosed.
CONCLUSION: Npt and β_2-MG in CSF appear to be valuable parameters for the diagnosis of HIV infection or secondary complications in the brain.

Th.B.P.245 THE CSF-HIV MARKERS IN THE DIFFERNT STAGES OF INFECTION

R. Pristerà, O.Moling, F. Tezzon*, E. Kofeann**, A. Castagna°, L. Grimaldi°° P. Mian, M. Marchesi, C. Vedovelli, G. Sölva, A. Lazzarin°, U. Gaspa**.
Inf.Dis.Dep.,*Neurol. Dep., ** Labor.: Gen. Hosp. Bolzano; ° Inf.Dis.Dep. Hosp. Sacco, °°Neurol. Dep. Hosp. S.Raffaele: University of Milano. Italy.

Objective. To compare the pattern of CSF-HIV markers with the serological ones.
Methods. 65 serum and CSF samples were collected simultaneously in 50 patients with HIV-infecttion and HIV-Ab,Ag (EIA), Env.-core recomb.(EIA), Western Blot, IEF assays were carried out.
Results. The following table summarizes the pattern of serum and CSF-HIV markers.

Months from inf. and pathology	number of samples	H.I.V.-Ag serum	H.I.V.-Ag CSF	Ab anti-core serum	Ab anti-core CSF	Ab anti-env. serum	Ab anti-env. CSF
<6	2	-	-	+	-	+	+
7-24	14	-	-	+	-/±	+	+
>25	19	-	-	+	+	+	+
A.I.D.S.	15	+/-	-	±/-	-	+	+
A.D./CNS-d.	15	+/-	+	-	-	+	+

legend:
A.D.: AIDS Dementia,
CNS-d.: CNS-disease others than AIDS.
+ : positive,
± : weak positive,
- : negative.

Conclusions. 1) The CSF-anticore Ab in acute infection are detectable later as compared with the serological ones; in intermediate stage the two patterns are analogous; in later stages of disease their disappearance from CSF anticipates the serological fall. 2) The CSF-antienvelope Ab are detectable precociously and persist. 3) The CSF HIV-Ag have been found only in patients with A.D. or CNS-diseases (this suggest that CNS-diseases may stimulate the viral replication in the CNS-cells infected by HIV).
The determination of these markers assume diagnostic and prognostic importance in all stages of HIV infection.

Th.B.P.246 Cerebrospinal fluid analysis in opportunistic brain infections.

Wilfried Lüer*, S. Poser*, G. Rögler**, H.D. Pohle** K. Felgenhauer* *Department of Neurology, University of Göttingen, ** Universitätsklinikum Rudolf Virchow (Wedding), Berlin, Federal Republic of Germany

Objective. To differentiate HIV encephalitis from opportunistic brain infections by CSF analysis.
Methods. Fifty-nine patients with AIDS were analysed, 29 patients had opportunistic brain infections (toxoplasmic encephalitis, cryptococcal meningitis, PML, viral and bacterial infection). Immunoglobulins G, A and M, intrathecal production of HIV antibodies and intrathecal production of Toxoplasma gondii antibodies were quantified by ELISA.
Results. Evidence for chronic HIV encephalitis was found in 52/59 patients by local HIV antibody production. Intrathecal IgG-production was found in 28% in HIV encephalitis, but no IgA-and/or IgM-synthesis. Opportunistic brain infections show local IgG-production (36%) as well as IgA (42%) and IgM (48%). Intrathecal produced T. gondii antibodies were found in 9/14 patients with toxoplasmic encephalitis, but not in other opportunistic infections.
Conclusion. Quantitation of immunoglobulins G, A and M is of high significance to detect opportunistic brain infections, intrathecal IgA and/or IgM production points to an opportunistic infection and was not seen in HIV encephalitis. Intrathecal T. gondii antibody production was found in 64% in toxoplasmic encephalitis and may be considered in diagnostic procedures.

Th.B.P.247 MODIFICATIONS BIOLOGIQUES DU L.C.R. AU COURS DE L'INFECTION PAR LE V.I.H.

SAINT-MARC T.*, VERGNE A.†, CAUDIE C.†, TOURAINE F.†, LIVROZET J.M.*, QUINCY Cl.†, TOURAINE J.L.*
*Pavillon P. Hôpital Edouard Herriot 69437 Lyon Cédex 03. FRANCE.
† Laboratoire d'Immunobiologie.Hôpital Neurologique 69394 Lyon Cédex 03. FRANCE.

Objectif: Définir le profil biologique d'évolution du LCR au cours de l'infection par le VIH.
Méthodes: Etude chez 45 patients VIH+ (20 patients avec complications neurologiques et 25 sans complications) des modifications cellulaires et protéiques du LCR par la recherche des synthèses intrathécales,d'IgG totales(index d'IgG) associées à la présence de bandes oligoclonales (BO), d'anticorps anti VIH confirmés par Western-blot et de l'antigène P 24.
Résultats: Les perturbations cellulaires (lymphocytose et/ou cytologie inflammatoire), l'augmentation de la protéinorachie avec modification de la perméabilité de la barrière sang-LCR et une synthèse intrathécale d'IgG en présence de BO,objectivent les complications neurologiques associées au VIH ou à une co-infection.
En l'absence de toute manifestation neurologique et dès le stade asymptomatique, nous observons des synthèses intrathécales d'IgG et d'anticorps anti VIH à des taux très élevés. L'évolution de la maladie vers le stade SIDA se traduit par une diminution significative de ces synthèses.

	AS	ARC	SIDA	témoins
Index d'IgG (x±SD)	1,07±0,53	0,73±0,16	0,67±0,14	N≤0,7
Index Ac anti VIH (x±SD)	6,3 ±3,1	5,1±4,8	2,1±2,1	N≤2
Présence de BO (%)	80	40	31	

L'antigène P 24 est présent chez 35% des patients au stade SIDA
Conclusion: Au tout début de l'infection,les perturbations biologiques du LCR sont plus fréquentes et plus marquées;ces résultats montrent que l'invasion du SNC par le VIH est très précoce.

Th.B.P.248 PRODUCTIVE INFECTION BY HIV OF HUMAN CENTRAL NERVOUS SYSTEM (CNS) TISSUES

Budka, Herbert. Neurological Institute, University of Vienna, Vienna, Austria.

Objective. To clarify frequency, cellular tropism, and relation to tissue pathology, of productive HIV infection in human CNS. Methods. Immunocytochemistry for HIV p17, p24, and gp41, for specific cellular markers, and for opportunistic pathogens, on serial sections of formol-fixed, paraffin-embedded CNS autopsy tissue of 57 patients (56 with AIDS) with various pathologies. Results. HIV antigens detectable in 37 cases (65%). In 26 cases large amounts of HIV in lesions histopathologically diagnosed as HIV-induced (Budka,Acta neuropathol 77:225,1989),including vacuolar myelopathy and leukoencephalopathy. In 7 cases isolated immunoreactive cells unassociated with pathology. In lesions of opportunistic infections HIV⁺ cells absent (24 cases) or rare (6 cases); only in 3 cases massive HIV coinfection. Immunoreactivity limited to cells with phenotype of microglia or macrophage. Conclusion. Productive HIV infection of the CNS is frequent in AIDS, with the microglia/macrophage as target. Early HIV production without associated pathology involves isolated microglia. Massive production of HIV is invariably associated with prominent and specific histopathology. HIV pathogenicity in the CNS appears as microglia/macrophage-mediated, possibly via secretion by productively infected cells of myelinotoxic factor(s). (Supported by the Lord Mayor's Medical-Scientific Fund, Vienna)

Th.B.P.249 CLINICAL-PATHOLOGICAL FEATURES OF HTLV-I ASSOCIATED MYELOPATHY (HAM) IN AIDS

Rosenblum, MR; Brew, Bruce J; Aronow HA; Hardy, W; Cronin, K; Price, RW. Memorial Sloan-Kettering Cancer Center, New York NY USA

Objectives: To delineate the clinical and pathological features of two patients coinfected with HIV-1 and HTLV-I, both of whom had HAM.
Methods and Results: Two black US residents, both with AIDS, were found to have HTLV-1 antibodies in the serum. The first patient had had symptoms of a myelopathy in 1973, 9 years before developing AIDS. His leg weakness was clinically stable until the last few months of life. The spinal cord pathology consisted of marked atrophy, meningeal fibrosis and small vessel proliferation without perivascular infiltrates or vacuolar myelopathy. The brain showed a multinucleated-cell encephalitis with detectable HIV-1 p24 antigen. The second patient had a myelopathy that developed in the terminal phase of AIDS and disseminated prostatic cancer. The spinal cord pathology was notable for meningeal fibrosis, proliferation of small vessels and minimal parenchymal perivascular infiltrates but again without vacuolar myelopathy. The brain showed white matter pallor and astrocytosis without detectable HIV-1 p24 antigen.
Conclusions: HAM may occur and progress in AIDS patients despite the concomitant immunodeficiency. Its clinical features are indistinguishable from vacuolar myelopathy but the pathological changes are separate. The relative lack of inflammation may pertain to 'burnt out' disease or the effects of immunodeficiency. Whether HAM pursues a different clinical course in HIV-1 infected patients awaits larger studies.

Th.B.P.250 CAN HIV-1 ALONE INDUCE A SUBACUTE ENCEPHALITIS? A MORPHOMETRIC AND IMMUNOCYTOCHEMICAL STUDY

Dominique, Hénin*; Reux, I.*; Vazeux, R.**; Sazdovitch, V.*; Katlama, C.*; Hauw, J.-J.*
*La Salpêtrière and **Institut Pasteur, Paris, France

Objectives. 1)To study the relationship between the topography of microglial nodules and multinucleated giant cells in a series of 30 patients with HIV-subacute encephalitis and their higher cortical function and 2)to determine by immunocytochemical methods how often HIV is associated with other pathogens (infections/tumors).
Methods. We studied 20 paraffin and 8 celloidin sections (250 cm2) in 30 cases and in 20 of them we reviewed numerous frozen sections (100 cm2) for immunodetection of HIV-1 antigens, toxoplasma, CMV and papova viruses.
Results. Sixty per cent had less than 10 microglial nodules. Multinucleated giant cells were observed in only 22/30 cases and 73% had less than 5 giant cells. Giant cells and microglial nodule densities were not statistically linked and neither was their number linked to other lesions. Microglial nodules were significantly more frequent in the basal ganglia and brain stem. Giant cells predominated in the pallidum and white matter. The presence of HIV-1 antigens did not depend on the density of microglial nodules or giant cells. in all cases, HIV-1 was detected in subacute encephalitis associated with opportunistic infections or lymphoma. There were no instances of subacute encephalitis associated exclusively with HIV-1.
Conclusion. 1) The topography of subacute encephalitis is mainly basilar. It predominates in structures known to be involved in subcortical dementias. 2) Opportunistic infections or lymphomas may either facilitate the entry of HIV-infected cells or trigger the replication of HIV-1 in latently infected reservoir cells of the brain and thereby lead to subacute encephalitis.

Th.B.P.251 INTERET DE L'ETUDE ULTRASTRUCTURALE LORS DES NEUROPATHIES PERIPHERIQUES ASSOCIEES A L'HIV.

Brion J.P.*, Mezin P.**, P. Leclercq*, J.P. Stahl*, P. Stoebner**, M. Micoud*
* Clinique Médicale et des Maladies Infectieuses - ** Laboratoire de Pathologie Cellulaire - Centre Hospitalier Régional - Grenoble - France

Objectif : L'atteinte neurologique périphérique possède un pronostic incertain. Nous avons étudié la relation entre la fréquence de survenue des inclusions tubuloréticulaires (ITR) en microscopie électronique, et la gravité de l'infection.
Méthode : 9 patients séropositifs atteints de neuropathie périphérique ont été étudiés : 5 SIDA, 2 ARC, 2 asymptomatiques. Dans tous les cas, l'électromyographie a confirmé la neuropathie et une biopsie neuromusculaire réalisée. L'examen a compris une étude en microscopie optique et électronique.
Résultats : Chez chaque patient, il a été noté une atrophie musculaire de type neurogène associée à une axonopathie avec ou sans démyélinisation. L'examen ultrastructural a révélé des ITR dans les vaisseaux endomysiaux dans 7 cas sur 9. Le pourcentage de vaisseaux contenant des ITR a été corrélé de façon significative avec l'intensité de l'atteinte neurologique, le stade clinique, et le rapport T4/T8.
Conclusion : Cette étude confirme l'intérêt de la mise en évidence et de la quantification des ITR chez les patients HIV + atteints de neuropathie. Leur fréquence de survenue paraît associé au stade évolutif de la maladie.

Th.B.P.252 EARLY ASTROCYTE INVOLVEMENT IN NEUROAIDS

Taruscio Domenica*, Malchiodi Albedi F.*, Paulussi S.**, Stagni G.**, Francisci D.*, Donelli G.*
*Laboratorio di Ultrastrutture, Istituto Superiore di Sanità, Roma; **Istituto di Malattie Infettive, Università di Perugia, Italy.

In the studies on the neuropathology of AIDS, astrocyte involvement has generally received little attention. The frequency and diffusion of astrocyte hyperplasia in cerebral tissue, however, better correlates with the frequency and seriousness of CNS involvement in AIDS, especially when compared with the incidence of other lesions, such as microglial nodules and multinucleated giant cells, which are considered the hallmarks of neuroAIDS. Here, we studied the patterns of astrocyte involvement on paraffin sections from the cortical tissue of 9 subjects, who had shown signs of diffuse CNS involvement before the exitus, by the immunohistochemical demonstration of GFAP. The most frequent modification was an increase in number and size of astrocytic foot processes around blood vessels, which was present in 8 out of 9 cases, was often associated with clustering of astrocytes around the vessels and was sometimes the only histological abnormality present in the grey matter. A diffuse increase in astrocytes was less frequent, especially in the grey matter. Microglial nodules, which were present in 2 cases, did not appear to be composed of astrocytes, although around them an increase in number and thickness of astrocytic cell processes was often evident. In 5 cases, hypertrophy as well as hyperplasia of astrocytes was observed. The finding of astrocytic foot processes hyperplasia, in absence of histopathological signs of other neural cell type involvement, suggests that astrocytes may be involved early in the neuropathology of AIDS.

Th.B.P.253 ETUDE PAR RESONANCE MAGNETIQUE DES ATTEINTES CEREBRALES AU COURS DU SIDA DE L'ADULTE: CONFRONTATIONS AUTOPSIQUES.

Trotot P.M, Sandoz-Tronca C, Lavillain R, Vazeux R, Mathiesen L., Gray F, Mikol J, Vedrenne C
Institut Pasteur, Paris, France

Objectifs: comparaison entre le diagnostic évoqué sur l'image de Résonance Magnétique (IRM) et l'analyse du cerveau post-mortem.

Méthode: à partir de 200 cerveaux examinés analyse des cas comportant IRM, anatomopathologie traditionnelle et étude après congélation par hybridation in situ et immuno-marquage.

Résultats: dans certains cas la corrélation est nette (abcès toxoplasmiques, LEMP à Papova virus), dans d'autres elle est plus difficile (lymphomes, cryptococcoses). Cependant le problème le plus délicat reste celui des encéphalites diffuses: signification des augmentations diffuses de signal des centres ovales? de la dilatation ventriculaire? des bordures ventriculaires renforcées d'un hypersignal? des zones de haut signal(ZHS) ponctiformes isolées ou disséminées? analyse des atteintes de la fosse postérieure?

Conclusion: la confrontation anatomo-imagerie permet d'avancer dans la compréhension de ces divers tableaux. Bien souvent les atteintes ne sont pas univoques et l'on retrouve 2, 3, voire 4 agents infectieux simultanés.

Th.B.P.254 APPORT DE L'IRM AU DIAGNOSTIC PRECOCE DES COMPLICATIONS ENCEPHALIQUES DU SIDA

P.M. Trotot, C. Sandoz-Tronca, M.Thibierge, A.E. Cabée, R.Lavayssiere, J.M. Bigot, J.Vignaud. Institut Pasteur, Paris

Objectifs: déterminer l'apport de l'Imagerie par Resonance Magnétique (IRM) au diagnostic des complications encéphaliques: encéphalites subaiguës ou lésions focales, infectieuses ou tumorales.
Méthode: A partir des dossiers des 300 derniers patients hospitalisés comparaison IRM/Tomodensitométrie(TDM). Confrontation avec les résultats des épreuves thérapeutiques, des biopsies stéréotaxiques et des autopsies.
Résultats: deux tableaux cliniques peuvent être opposés:
-apparition brutale de fièvre et de troubles neuro-psychiques
-détérioration progressive de début insidieux.
Dans le premier cas la TDM est souvent suffisante pour reconnaître l'existance d'une ou plusieurs lésions focales, cependant la détection précoce des lésions toxoplasmiques est le fait de l'IRM avec ou sans Gadolinium..
Dans le second l'IRM permet de différencier lésions focales et diffuses, parmi lesquelles plusieurs types sont identifiés: plages discontinues sous-corticales (Leuco encéphalites à papova virus), lésions ponctuées plus ou moins dispersées, hypersignal diffus des centres ovales, avec ou sans dilatation ventriculaire.
Conclusion: essai de mise en place d'un algorythme de décision.

Th.B.P.255 SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY (SPECT) FINDINGS IN HIV INFECTION, PRELIMINARY RESULTS.

Pigorini F.°;Pau F.M.°;Galgani S.^;Narciso P.°; Ronci M.A.°;Visco Giuseppe et al.
U.S.L. RM/10 "C.Forlanini"Hosp., Nuclear Med. Dept.°;"S.Camillo"Hosp., Neurology Dept.^;
"L.Spallanzani" Hosp. Infect.Dis. Dept.°, Rome, Italy.

OBJECTIVE. To evaluate the sensitivity of SPECT cerebral blood flow studies to disclose brain involvement in HIV infection in comparison to CT scan and NMR findings.
METHODS. This study includes 25 patients. 17 AIDS, 4 ARC and 4 HIV seropositive all with neurological signs or symptoms. Local cerebral blood flow was evaluated by 99mTC-HM-PAO SPECT and related to clinical, CT and NMR findings.
RESULTS. SPECT showed pathological findings consisting in cortical thinning, cortical focal hypoperfusion and basal ganglia hypoperfusion in 25/25 cases. Cortical hypoperfusion was more frequently observed in frontal cortex (16/25). CT was positive in 14/18.
CONCLUSIONS. Our preliminary data on SPECT cerebral blood flow studies in HIV related cerebral diseases are encouraging. Nuclear results are of course not specific, but they may be very sensitive in showing pathophysiological dysfunction at an earlier stage than CT or even NMR, even if the possibility of "false negatives" has to be taken into account. There is, thus, the concrete hope to disclose neurological involvement in asymptomatic HIV seropositive patients.

Th.B.P.256 BRAIN MAGNETIC RESONANCE IMAGING (MRI) FINDINGS IN HIV INFECTION.

Tozzi V.°;Ciciani R.°;Galgani S.°°;Ronci M.A.°;Volpini V.°°;Visco Giuseppe°et al.
U.S.L. RM/10,"L.Spallanzani"Hospital, Dept. Infectious Diseases°; &
"S.Camillo" Hospital, Dept. Neurology °°, Rome, Italy.

OBJECTIVE. To define MRI patterns of brain involvement in HIV infection and to correlate these findings to the clinical, pathological and TC brain data.
METHODS. MRI and TC of the brain were performed in 107 HIV Ab+ ve patients with neurological signs or symptoms. MRI findings were compared to the clinical picture in all patients and, in 20 of them, also with the pathological diagnosis.
RESULTS. The following MRI patterns on T2 weighted images were observed:
A) an enlargment of the cortical sulci and ventricles was detected in most patients indipendently to the clinical and pathological diagnosis; B) hyperintense signal areas ranging from patchy to confluent lesions within the white matter were observed in HIV encephalopathy only; C)solitary or multiple hyperintense areas localized in the cortical and subcortical regions were present in primary CNS lymphoma and in neurotoxoplasmosis; D) multiple, focal hyperintense areas in the deep white matter of front-parieto-occipital lobes were noticed in multifocal progressive leukoencephalopathy; E) small solitary or multiple subcortical hyperintense lesions were detected in different conditions but any specific correlation was found in our patients.
CONCLUSION. MRI patterns abnormalities, although being largely useful in suggesting differential diagnosis in HIV patients with neurological symptoms, cannot be considered as pathognomonic. MRI seems to be a highly sensitive method for diagnosis of brain involvement, particularly for the early detection of HIV encephalopathy.

Th.B.P.257 CEREBRAL ATROPHY IN HIV-1-INFECTED PATIENTS: RELATIONSHIP TO NEUROLOGICAL AND NEUROPSYCHOLOGICAL MEASURES

Aronow, Howard; Keilp, JG.; Krol, G; Brew, BJ; Sadler, AE; Dorfman, D; Sidtis, JJ; Birnhak, L; Rottenberg, DA; Price, RW. Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Objective: To evaluate the relationship between cerebral atrophy, assessed by computerized tomographic (CT) head scans, and neurological and neuropsychological impairment in HIV-1-infected patients.
Methods: 34 patients (age <50) received a total of 42 CT scans in the context of clinical evaluation. Patients were examined neurologically, staged with respect to the severity of the AIDS dementia complex (ADC), and received neuropsychological tests. Using a set of predefined "standards", scans were assigned numerical ratings corresponding to normal, mild, moderate, or severe with regard to sulcal, ventricular, and Sylvian fissure enlargement. Ratings were summed to derive an overall index of atrophy.
Results: Cerebral atrophy increased significantly with increasing ADC ($p<.05$); moderate to severely demented patients had significantly greater atrophy than equivocally or mildly demented patients ($p<.05$). Atrophy correlated with the following neuropsychological tests: Trail Making A ($p=.03$) and B ($p<.01$), Digit Symbol ($p<.01$), Verbal Learning ($p<.01$), and Timed Gait ($p=.02$).
Conclusions: Mild cerebral atrophy may be seen in patients without clear functional neurological impairment, while more severe atrophy correlates with progressive ADC and worsening neuropsychological performance.

Th.B.P.258 AUTORADIOGRAPHIC ANALYSIS OF AIDS BRAIN LESIONS WITH AN ω3 (PERIPHERAL TYPE BENZODIAZEPINE) BINDING SITE RADIOLIGAND

Hauw, Jean-Jacques ; Cornu, P.; Sazdovitch, V.; Grilla, M.; Duyckaerts, C.; Hénin, D. Hôpital de la Salpêtrière, Paris, France.

Objective. To describe the brain localization of ω3 sites in AIDS encephalopathy.
Methods. Postmortem brain samples from 5 cases of AIDS subacute encephalitis and from 3 control brains were frozen in isopentane and processed for ω_3 autoradiography as previously described (1,2, 3). An irreversible (^{3}H PK 14105) ω_3 radioligand was used to determine the microscopic localization of these binding sites on H-E stained sections. In addition, the following stains were performed on serial sections : acid phosphatase, Leu-M3, Leu- M5, Ki M6, Ki M7, anti GFAP and anti HIV (p18 and p25) antibodies.
Results. In AIDS subacute encephalitis, the emulsion autoradiography of irreversibly bound ^{3}H PK 14105 could label either single cells or cell clusters grouped to form microglial nodules or perivascular cuffs. Other techniques suggested a predominant macrophage localization of these sites. ω_3 sites were seen as well in HIV+ as in HIV- brains.
Conclusion. ω3 sites label macrophages in AIDS encephalitis as they do in other neurologic diseases (3), and not the presence of HIV-1. The available positron (^{11}C-PK 11195) and γ ray (^{125}I-PK 11195) emitting ligands of ω_3 sites (4,5) may render possible their in vivo detection and help to the diagnosis and study of AIDS subacute encephalitis.

Th.B.P.259 CEREBRAL METABOLIC (PET), NEUROPSYCHOLOGIC AND NEUROLOGIC ABNORMALITIES IN PATIENTS WITH AIDS

Van Gorp, W.; Mandelkern, M.; Ropchan, J., Evans, G., Blahd, W., Flynn, F., et al. West Los Angeles Veteran's Administration Medical Center and UCLA School of Medicine, Los Angeles, CA, U.S.A.

Objective. To determine the relationship between cerebral metabolic function and neuropsychologic/neurologic status in persons with AIDS.
Methods. Seventeen consecutively referred persons with AIDS were studied using Positron Emission Tomography (PET) with 2-Fluro-2-Deoxy-D-Glucose as a tracer and comprehensive neuropsychologic examinations. Subjects were also rated for severity of dementia using Sloan-Kettering staging criteria (S-K) for AIDS Dementia Complex using a neurologist's rating. All ratings were performed independently.
Results. Seven of the 17 (41%) subjects demonstrated both PET abnormalities and neuropsychological dysfunction while 3/17 (18%) demonstrated both normal PET and neuropsychologic studies. Neuropsychologic testing classified 12 of the 17 subjects as abnormal (1 1/2 s.d. below the mean on 3 or more measures), while clinically identified PET abnormalities occurred in only 6 of the 17. Of these 6, five were also outliers on the neuropsychologic test battery and 4 were rated as 1 (mild) or higher on the Sloan Kettering scale. Two of the 6 subjects who demonstrated abnormal PET scans did not achieve neuropsychological outlier status using the criterion listed above.
Conclusion. Neuropsychologic abnormalities were more prevalent in our AIDS sample than clinically identified cerebral metabolic dysfunction using PET. Neuropsychologic and neurologic abnormalities may occur in the absence of clear cerebral metabolic dysfunction using clinical interpretation in persons with AIDS. Statistical examination using regions of interest on PET may reveal greater findings of cerebral metabolic dysfunction than did clinical interpretation used in this study.

Neurologie : atteintes neurologiques du VIH asymptomatique
Neurology: Neurological Involvement in Asymptomatic HIV

Th.B.P.261 ABSENCE OF NEUROLOGICAL DISEASE EARLY IN HIV INFECTION

Marder, Karen; Bell, K.; Dooneief, G.; Gorman, J.; Todak, G.; Williams, J.B.W.; Erhardt, A.; Mayeux, R.
HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, NY, U.S.A.

Objective: To document overt neurological disease after seroconversion in a large cohort of gay men in N.Y.C.
Methods: A structured neurologic exam, including a functional disability rating scale, was developed and validated. Examiners were blind to the HIV status of subjects. Medical staging was independent of the neurologic exam and a standard psychiatric interview.
Results: 160 gay men, 118 HIV+ and 42 HIV-, were evaluated. 55 men were asymptomatic, 31 were mildly symptomatic, 32 had ARC, and none had AIDS. Age, race, handedness and education were similar in the HIV+ and HIV- groups. Complaints of mildly decreased concentration and memory impairment were noted more often in the HIV+ group, but cranial nerve abnormalities, pyramidal tract signs, extrapyramdical features, frontal release signs, evidence of peripheral neuropathy, and abnormalities on a 19 item mental status test were equally prevalent in HIV+ and HIV- men.
Conclusion: Historically, neurologic signs may be present transiently at the time of seroconversion. Overt, non-cognitive, neurological manifestations are not more prevalent in HIV+ men. Prior studies documenting frequent neurological findings in seropositive men may not have included appropriate comparison groups. Seronegative "at risk" individuals must be included in studies.

Th.B.P.263 T4 LYMPHOCYTE COUNTS AND THE PRESENCE OF ABNORMALITIES ON NEUROLOGICAL EXAMINATION IN ASYMPTOMATIC HIV SEROPOSITIVE SUBJECTS

Joseph R. Berger, M.D.*^, M. McCarthy*, L. Resnick^, M. A. Fletcher^, N. Klimas^, E. Lo#, L. Pall*.
From the Departments of Neurology*, Internal Medicine^, and Pediatrics#, the University of Miami School of Medicine, and the Department of Dermatology^, Mt. Sinai Medical Center, Miami, Florida, U.S.A.

The presence of abnormal neurological findings on entry examination in 91 asymptomatic HIV seropositive subjects was correlated with T4 lymphocyte count. Performance on a mini mental status examination was more often impaired in subjects with T4 <600 cells/cu mm (62.5% v. 32.3%). Four of 35 (11.4%) subjects with T4 <400 had abnormal ocular smooth pursuit compared to 0 of 56 with higher counts. Postural instability to threat was also twice as common (19% v. 9%) in the former group and tended to be of greater magnitude. Neither frontal release signs (snout, grasp, glabellar, palmomental) nor a brisk jaw jerk correlated with T4 levels.

Elevated serum p24 Ag (>20 pcg/ml) was detected in 13% of subjects with T4 <400, but in none of the subjects with T4 $\geq$400. p24 antigen was negative in the CSF of all asymptomatics. Serum p24 Ag was more highly predictive, though not as sensitive, as T4 counts for the appearance of neurological abnormalities.

The appearance of abnormalities of mental status, ocular smooth pursuit, and postural stability correlated with the T4 level and presence of serum p24 Ag in asymptomatic HIV seropositive subjects.

Supported by National Institute of Neurological Diseases and Strokes Program Project P01-NS25569.

Th.B.P.260 HM-PAO SPECT AND GD-DTPA ENHANCED MR IMAGING IN CNS-MANIFESTATIONS OF AIDS

Cordes, M.*; Henkes, H.*; Hunger, J.*; Jochens, R.*; Heise, W.** and Felix, R.*.
*Department of Radiology, University Clinic Rudolf Virchow / Charlottenburg, Free University Berlin, ** Auguste Viktoria Hospital, Berlin, W-Germany

Although CT and MR imaging have demonstrated a high sensitivity in detecting brain lesions, determination of the etiology causing the lesion is still poor. However, specificity is crucial for prognosis and therapy.

Objective: To determine the diagnostic value of HM-PAO SPECT in patients with intracranial AIDS manifestations, which had been confirmed by MR. In aridition, the incidence, the localisation as well as the degree of altered brain perfusion in AIDS-patients with clinical symptoms of CNS disease and a normal MR examination was investigated.

Methods: Eleven male patients (age median: 37 years) with proved HIV-1 infection, CDC IV, were examined. Clinical and/or histologic diagnoses were toxoplasmosis (6 patients), lymphoma (2 patients), meningitis (1 patient), and HIV-encephalitis (2 patients). SPECT examinations were performed using a rotating gamma camera after i.v. application of 555 MBq 99mTc-HM-PAO. Axial, coronal and sagittal slices were generated. MR studies (0.5 T Magnetom) were performed using T2-weighted images (SE 1600/30,70) and unenhanced as well as Gd-DTPA enhanced T1-weighted sequences (FLASH 315/14, α=90°).

Results: MR imaging demonstrated 20 lesions in 6 patients with cerebral manifestation of toxoplasmosis. SPECT demonstrated focally altered brain perfusion in all patients. Twelve of the 20 lesions showed hypoperfusion, 5 lesions were hyperperfused, one patient of this group had multiple perfusion deficits. In one patient with 3 cerebral lymphomas, all lesions were hypoperfused. In one patient with meningitis - as demonstrated by MR - perfusion was reduced in the adjacent brain tissue. In 2 patients with HIV-encephalitis and negative MR, SPECT detected multiple perfusion deficits.

Conclusion: The sensitivity of SPECT in detecting focal lesions is inferior to MR. At present, HM-PAO SPECT does not provide differentiation between toxoplasmosis and lymphoma. However, SPECT demonstrates altered brain perfusion in areas larger than the corresponding focal lesion detected by MR imaging. SPECT appears thus potentially useful in AIDS-patients with symptomatic brain disease and a negative MR who may have altered brain perfusion. HM-PAO SPECT is a helpful diagnostic method complementary to CT and MR imaging in patients with AIDS-related brain disease evaluating the brain perfusion pattern.

Th.B.P.262 NEUROPSYCHOLOGICAL CHANGE IN CDC II, III AND IV PERSONS AFTER 6 TO 12 MONTHS: EVIDENCE FOR DECLINE

Grant, Igor; Heaton, R.K.; Jernigan, T; Hesselink, J; Atkinson, J.H.; Weinrich, J. and McCutchan, A.J.
University of California, San Diego and San Diego Veterans Administration Medical Center, La Jolla, CA, USA

Objective: Neuropsychological (NP) deficit has been reported in 30% to 87% of patients with AIDS and in 5% to 44% of persons in CDC II and III. However, few longitudinal NP studies are available. We report on patients in CDC classes II, III and IV re-examined after 6 to 12 months as a part of a longitudinal study.
Methods: Gay men in the following groups were re-examined at 6 to 12 months: CDC IV - N=6; CDC II/III - N=18; HIV- controls - N=5. NP testing included extended Halstead-Reitan battery. Ratings of "change" were performed by clinicials blinded to group status. MRI brain scans, using a 1.5T GE Signa system were also obtained.
Results: At followup 3 of 6 AIDS patients (50%), 4 of 18 CDC II/III (22%), and 0 of 5 controls (0%) were rated as worse. Worsening was not associated with initial neuropsychological rating, nor interim drug use/mood disorder or CD4+ count. Computer assisted analysis of baseline MRI indicated that those who subsequently worsened on NP had increased cortical fluid and subcortical hyperintensities.
Conclusion: This limited series suggests that neuropsychological decline can occur in AIDS patients even after 6 months and in some CDC II/III persons after 12 months. It is possible that subtle structural brain changes may presage neuropsychological decline, as indicated by computer assisted analysis of MR images.

Th.B.P.264 NEUROLOGIC FINDINGS IN EARLY HIV INFECTION

Coats, Michael; Salazar, A.M.; Martin, A.; Jabbari, B.; Geyer, C.; Burke, D.; & Walter Reed Retrovirus Research Group.
Uniformed Services University of the Health Sciences, Bethesda, Maryland; Walter Reed Army Medical Center, Washington, DC, USA.

Objective. To investigate possible neurologic abnormalities in early HIV infection.
Methods. A standardized neurologic examination, lumbar puncture, MRI, EEG, and evoked potentials were done on 54 patients referred with early HIV infection (14% Walter Reed [WR] Stage 1; 54% WR-2; 15% WR-3; 5% WR-4; 8% WR-5).
Results. Subtle neurologic and electrophysiologic anomalies were noted in only 12% of cases, but CSF cells, protein, IgG, and/or oligoclonal bands (OCB) were abnormal in at least 82% (including 6/8 in WR-1); and CSF HIV cultures were positive in 8/22 (36%). Positive CSF HIV cultures were related to abnormal CSF IgG (rho=.55, p<.02) and to CSF cell count >10 (rho=.45, p<.05). However, there was no significant correlation between positive CSF HIV cultures and other neurologic findings. Similarly, there was no significant correlation between WR Stage and CSF cells, protein, IgG, OCB, or HIV cultures. Sulcal widening on MRI (reported clinically in 17/54 patients vs. 2/12 matched controls) did not correlate with other clinical or CSF parameters.
Conclusions. A large percentage of neurologically asymptomatic patients with HIV infection showed laboratory abnormalities consistent with CNS involvement by the virus. However, there is no clear correlation at this time between these findings and clinical stage of illness.

Th.B.P.265 MOTOR DYSFUNCTION AND COGNITIVE DISTURBANCES IN 5o CLINICALLY ASYMPTOMATIC HIV-INFECTED PATIENTS WITH NORMAL MRT-SCANS

Arendt,G.[+], Hefter,H.[+], Elsing,C.[++] and Freund,H.-J.[+]
Depts. of Neurology[+] and Medicine[++], Univ. of Duesseldorf
4ooo Duesseldorf Moorenstr. 5 FRG

Objective: In an open, prospective study, motor and cognitive function was examined in 5o HIV-infected patients without evident neurologic or psychic deficit in comparison to an age- and sex-matched control group. Methods: Patients were excluded from the study in the case of alcohol or drug abuse, fever and/or opportunistic cerebral infection. Patients underwent detailed psychometric testing, EEG- and ERP-recordings and MRT-scanning. In the motor tests, hand tremor, most rapid voluntary alternating index finger movements (AFM) and most rapid isometric index finger extensions (IFE) were analysed. Results: Motor abnormalities were detected in 8o% of the patients. The frequency of AFM and rise time of IFE showed statistically significant slowing in the patient group in comparison to the controls, whereas tremor peak frequencies were nearly the same in both groups. Cognitive testing of the acoustically evoked event related potential (P 3oo) revealed abnormalities in 48%. According to the clinical examination (no deficit), psychometric testing revealed an intelligence deficit in six cases only. 17 of our 5o patients showed EEG-abnormalities in a routine recording according to the 1o/2o-system. Surprisingly, none of the MRT-scans showed structural deficits. Conclusions: It is concluded, that electrophysiological methods are more sensitive in detecting subclinical CNS-affection in HIV-infected patients than neuro-imaging procedures.

Th.B.P.266 CHOICE-REACTION TIME MEASURES AND COGNITIVE DYSFUNCTION IN PERSONS WITH HIV INFECTION.

Perdices, M; Cooper, D.
NHMRC AIDS Research Unit, Sydney, Australia.

Objective: To examine the relationship between choice-reaction time latencies (CRL) and performance on other neuropsychologic (NP) measures in persons with HIV infection. Background: We reported earlier that complex processing speed is impaired in ARC and AIDS patients, but not those with HIV- asymptomatic infection. In this study we examined whether CRL was associated with specific NP abnormalities on these subjects. Methods: A battery of 26 tests covering a wide range of cognitive functions, was administered to 79 subjects (AIDS=18, ARC=18, HIV-Ab+ asymptomatic=20, seronegative controls= 23). Results: A significant diagnostic group effect (1-way ANOVA) was found on 8 tests (immediate verbal recall and storage capacity, multiple visuomotor tracking, complex sustained attention, motor coordination). CRL had a negative significant correlation with scores on 3 of these tests, and with 10 of the tests for which there was no significant group effect. Discriminant function analysis (using the 8 tests with a significant group effect and CRL as criteria) correctly classified subjects as follows:

	PERCENT CORRECT CLASSIFIED			
DISCRIMINANT CRITERIA	CONTROL	HIV-Ab+	ARC	AIDS
CRL & 8 test scores	66.7%	55.0%	50.0%	44.4%
CRL score only	78.3%	10.0%	5.6%	61.1%

Conclusion: CRL are significantly correlated with abnormal performances on some NP tests, but not others. By itself, CRL is a less sensitive criteria than when used in conjunction with other NP tests for discriminating asymptomatic and ARC patients, but more sensitive for discriminating AIDS patients and controls.

Th.B.P.267 INCIDENCE OF MILD NEUROPSYCHIATRIC ABNORMALITIES IN HIV INFECTED PATIENTS IN KINSHASA, ZAIRE

Luabeya, Mesu'a-Kabwe *,***, Kayembe K *, Mussa M *, Kayembe K **, Izzia K ** , Bertrand WE ***
* Dept of Neurology , ** Dept of Internal Medicine, *** School of Public Health, University of Kinshasa, Kinshasa, Zaire

Objective: To describe mild neuropsychiatric abnormalities in HIV-infected patients in Zaire.
Methods: For one week all inpatients of the Dept of Internal Medicine were examined by a team of neuropsychiatrists.
Results: Twenty-one patients (10 males, 11 females) were examined (age range: 15-49 years). Fifteen (71%) had symtoms and signs of neuropsychiatric impairment, including: forgetfulness, poor concentration, behavioral changes, sleep disorders, seizures, headache, vertigo, gait disturbances, tremor, myalgia, urinary sphincter disturbance. Neuropsychiatric findings were: frontal release signs (9), generalized hyper-reflexia (4), valleix signs (4), mental slowness (2), memory disturbances (2), dejection (2), neck stiffness (2), hypotonia (2), hyperpathia (2) and tremor (1).
Conclusions: Careful neuropsychiatric examiniation reveals a high incidence of isolated or poorly grouped neuropsychiatric signs which should allow the general practitioner to orient the patient for an early and better management. This study will be continued, and further studies are necessary to understand the significance of these signs.

Th.B.P.268 UNCOMMON NEUROLOGIC MANIFESTATIONS IN HIV-1 INFECTED PATIENTS WITHOUT AIDS

Erice, Alejo; Fortún, J; Hermida, JM; Nash, R; and Buzón, L. Division of Infectious Diseases. Hospital Ramón y Cajal. University of Alcalá Medical School. Madrid, Spain.

Objective. To describe uncommon neurologic manifestations in 3 HIV-1 infected patients (Pt) without AIDS.
Methods. Three Pt with HIV-1 infection demonstrated by positive ELISA and Western-blot presented clinically with acute neurologic dysfunction. Pt1 was homosexual; Pt2 and Pt3 were IV drug abusers. Pt1 and Pt2 had an acute cerebellar syndrome (ataxia, dysarthria, hypotonia, nystagmus and kinetic tremors). Pt3 presented with acute meningitis.
Results. CT scans of the brain were normal in all cases. CSF analysis showed slightly elevated protein levels in all Pt; in Pt3 there was lymphocytic pleocytosis and depressed CSF sugar levels. Exhaustive microbiologic and cytologic studies of CSF samples were negative in all Pt. Opportunistic infections or other etiologic entities were not demonstrated. Pt1 died 3 weeks after admission of an aspiration pneumonia. Pt2 has been followed 4 months and improved on oral zidovudine therapy (ZDV Rx). Pt3 remains stable after 15 months of follow up (6 on oral ZDV Rx) with chronic meningitis and low CSF glucose.
Conclusion. Atypical neurologic syndromes could be the first clinical expression of HIV-1 infection. These syndromes are probably due to HIV-1 infection of the central nervous system. ZDV Rx therapy could be beneficial in these situations.

Th.B.P.269 NEUROPSYCHOMETRIC FUNCTION IN EARLY HIV POSITIVE PATIENTS COMPARED WITH A MATCHED HIV NEGATIVE POPULATION

Clifford, David[*]; Miller,J.P.[**]; Seyfried,W.[**]; Glicksman, M.; Jacoby, R.
Washington University School of Medicine, Depts. of Neurology[*] and Biostatistics[**], and the Washington University AIDS Clinical Trial Group, St. Louis, Missouri 63110 USA.

Objective: Compare the neuropsychologic performance of uncomplicated CDC Stage II/III patients with similar uninfected subjects to suggest the earliest area of neurologic deterioration due to the HIV virus.
Methods: Trained psychometricians evaluated 29 HIV positive patients without history of alcohol or CNS active drug ingestion to compare with a volunteer population of high risk individuals seeking anonymous serum HIV test. Evaluations included the Folstein Minimental Status exam, word fluency for the letters S and P, grooved pegboard, an abbreviated Boston naming test, fingertapping speed, mental control, digit span, block design, digit symbol test, and paced auditory serial addition test (PASAT). In addition, patients were tested for depressive symptoms with the Beck Depression scale.
Results: A well matched population of 34 HIV negative subjects is compared to 29 HIV positive subjects. The positive subjects denied any current CNS active drug use including more than one drink of alcohol per day. Beck depression scales were not different between the groups, and the differences in age (32.53 vs 35.08 yrs) and education(15.0 vs 16.07 yrs.)were co-varied due to slight statistical differences between the groups. Digit span(17.0 vs 15.0, p=.009), block design(40.9 vs 34.7, p=.003) and PASAT-2,3,4 (37.3,32.1,25.8 vs 32.8,28.1,21.1 p=.03,.03,.05) all showed statistically significant declines in performance in the HIV infected group.(results compare least square means for negatives vs positives and significance) The PASAT at the slowest repetition rate showed no difference indicating a similar ability to perform the test, but all three faster repetition rates showed decline in performance in the infected groups. Analysis of 18 measures showed significance or trend toward declining performance in HIV positives, while one measure showed identical performance. (mental control)
Conclusion: HIV infection is associated with measurable decline in performance on several tests, which may be most useful in monitoring the earliest neurological manifestations of the infection. Serial testing over time will be necessary to confirm the clinical significance of these findings. They suggest that evaluation of early treatment of HIV neurologic disease may be possible before clinical manifestations of dementia are noted.

Th.B.P.270 CENTRAL NERVOUS SYSTEM FINDINGS AND NEUROLOGIC(N) CORRELATES OF HIV INFECTION IN MEN WITH CDC GROUP II/III HIV DISEASE

Collier, Ann; Marra, C; Coombs, R; Cohen, W; Claypoole, K; Handsfield, H et al.
University of Washington, Seattle, WA, USA.

Objective. To describe N and neuropsychologic(NP) findings in the absence of overt N disease in CDC group II/III HIV+ compared to HIV- homosexual subjects, and to characterize results of magnetic resonance imaging(MRI) and cerebrospinal fluid(CSF) studies in the HIV+'s.
Methods. Standardized history(HX), T cell subsets, blinded N exams and blinded 4 hour NP test battery on all subjects; MRI and lumbar punctures (LP) in HIV+'s.
Results. The 55 HIV+'s differed from the 39 HIV-'s in age(mean 38.3 vs 33.8, P=0.001), lifetime sex partners(median 200 vs 80, P=0.001), HX of fatigue(33% vs 8%, P=0.005), and CD4 counts (mean/mm^3, 480 vs 776, P=0.0001). Subjective N symptoms were present in 46(84%) of HIV+'s vs 29(74%) of HIV-'s(P=NS). Cranial nerve abnormalities were more common in HIV+'s than HIV-'s(27% vs 7%, P=0.019), although sensory, motor, cerebellar, and reflex findings were no different. Mini-mental status scores were identical(mean 29.1 and 29.2). NP test results were similar for the areas of language, motor, and emotional functioning, but tended to be more impaired in HIV+'s than HIV-'s in selected tests of visual memory, attention and abstract concept formation. Among the 41 HIV+'s undergoing LP, CSF WBC's were >5/mm^3 in 26(63%) and protein >45mg/dl in 17(41%). Of these 41, 21(51%) were culture positive for HIV in CSF. CSF HIV+'s tended to have lower CD4 counts than CSF HIV-'s (mean/mm^3, 631 vs 489, P=0.08). Routine CSF parameters (cell count, protein, glucose) were not different among those with and without detectable CSF HIV. Diffuse white matter abnormalities on MRI were present in 5/21 HIV CSF+'s vs 0/20 HIV CSF-'s(P<0.045); other intracranial MRI findings were present in 10/21 vs 8/20, respectively (P=NS). Routine CSF parameters did not correlate with MRI findings.
Conclusions. Cranial nerve findings and selected NP test results differed in HIV-'s vs HIV+'s with asymptomatic or clinically mild HIV infection. CSF HIV infection, elevated cell counts and protein, and MRI lesions were common in HIV+'s. Diffuse white matter abnormalities on MRI correlated with detection of CSF HIV by culture, but the clinical significance remains to be determined during follow-up.

Th.B.P.271 NEUROPSYCHOLOGICAL ABNORMALITIES AMONG ASYMPTOMATIC IV DRUG USERS: NO RELATIONSHIP WITH HIV-1 SEROSTATUS.

Selnes, Ola A., Proctor, T.V.; Royal, W.R.; Herman, C.; Vlahov, D.; McArthur, J.C., The Johns Hopkins Medical Institutions, Baltimore, MD USA

Objective: To determine if neuropsychological (NP) test performance among asymptomatic IV drug users (CDC Groups II/III) differs as a function of HIV-1 serostatus.
Methods: A neuropsychological (NP) test battery was administered to 42 unselected participants in a prospective study of the natural history of HIV infection in IV drug users. The NP testing was done without knowledge of serostatus, and included the Symbol Digit, Digit Span, Trail Making Test, Grooved Pegboard, Finger Tapping, Rey Complex Figure and the Brief Symptom Inventory.
Results: At baseline, 41% of the participants enrolled were HIV-1 seropositive. All were classified as CDC stage II or III, and none were taking azidothymidine (AZT). There was no significant difference in age, education, self-reported learning disability or drug use between HIV-1 seropositive and seronegative controls. Comparison of group means revealed no differences in NP performance between serostatus groups on any of the measures. The number of participants classified as having abnormal NP performance was equally high among both seropositive (50%) and seronegative (48%) participants (chi square= 0.014, p >.90).
Conclusions: Our results to date show that NP abnormalities are common among IV drug users, but there is no increase in such abnormalities among asymptomatic HIV-1 seropositives in CDC Groups II/III compared with seronegative controls. These findings are consistent with those from other HIV-1 infected populations showing no evidence of increased NP abnormalities during the asymptomatic stages of the infection.

Neurology: Miscellaneous (i.e., Testing: Psychology, Physiology, Electrophoresis)

Th.B.P.272 NEUROPHYSIOLOGICAL DIAGNOSIS OF AIDS DEMENTIA COMPLEX: ELECTROENCEPHALOGRAPHIC STUDY ON 271 HIV-POSITIVE SUBJECTS

A. PARISI, M. STROSSELLI, G. BARBARINI, L. MINOLI & E.G. RONDANELLI (Dept. of Infectious Diseases, University of Pavia IRCCS Policlinico San Matteo; 27100 Pavia, Italy)

Summary
The Authors report the results obtained by an electroencephalographic screening of 271 HIV-seropositive patients, belonging to different stages of infection.
The major bioelectrical changes of cerebral activity were recorded in patients with AIDS (90.6%) and ARC (60%), whereas mild abnormalities were present in the LAS patients (30.8%) and those carrying an asymptomatic infection (20.7%), often without any evidence of neuro-psycological impairment. Therefore, we emphasize the usefulness and sensitivity of the electroencephalography, in particular when coupled with Computerized Spectral Analysis (EEG-CSA) and Mapping, with the aim of identifying the subclinical stages of HIV-related subacute encephalitis.

Th.B.P.273 EEG BACKGROUND SLOWING APPEARS IN HIV-INFECTED PATIENTS IN THE ABSENCE OF METABOLIC DERANGEMENTS OR OTHER CEREBRAL INVOLVEMENT.

Norcross-Mechay, K.*; Borucki, Michael J.**; Borucki, S.J.*; and Pollard, R.B.**. *Neurology Department and **Division of Infectious Diseases, Department of Internal Medicine, University of Texas Medical Branch at Galveston,Galveston, TX, U.S.A.

Objective. To describe electroencephalographic (EEG) background changes that occur in association with HIV infection and that cannot be attributed to other known metabolic or cerebral abnormalities.
Methods. Patients with concomitant, known CNS disease (infection, tumor, CVA), drug intoxication, or metabolic derangements were excluded from the analysis. 179 HIV-infected patients had at least one EEG and 46 patients had subsequent EEGs at intervals of not less than one month.
Results. Patients with serial EEGs demonstrated decreasing background frequency ($p < 0.001$). Patients in CDC group II had normal alpha rhythms as did more than half of patients in group III. Patients in groups IVA, IVC1, IVC2, and IVD (without primary CNS lymphoma) had abnormal slowing of the alpha rhythm (8.69Hz, SD=0.26, N=102), and patients thought to have HIV-encephalopathy had even slower rhythms (6.64, SD=0.55, N=7) when compared to age-matched and sex-matched controls. Background slowing increased with advances in disease stage and with decreases in the log of absolute CD4+ counts.
Conclusion. Abnormally slow alpha rhythms were present in the absence of alternate metabolic or focal CNS disease that could have adversely affected the EEG background rhythm and may be a manifestation of infection with HIV.

Th.B.P.274 THE NEUROPHYSIOLOGY OF SLEEP DESTRUCTION IN PATIENTS WITH CNS-MANIFESTATIONS OF AIDS

Terstegge, Klaus*; Henkes, H.**; Raf, B.***; Scholz, G.*; and Kubicki, St.*.
*Departments of Clinical Neurophysiology, **Radiology and ***Internal Medicine II, University Clinic Rudolf Virchow, Free University Berlin, W.-Germany

Objective. To investigate the electroencephalographic phenomena of sleep in AIDS patients with proved CNS manifestation..

Methods: 19 patients with various cerebral manifestations of AIDS were examined. Diagnoses ranged from mild mental disturbances to severe brain damage caused by opportunistic infections. All patients underwent a whole night sleep-EEG recording (21- channel Mingograph, 21 gold electrodes in the positions of the international 10:20-system, reference montage to Cb). Visual as well as computer-assisted evaluation was performed. Sleep stages were determined according to the rules of Rechtschaffen and Kales, sleep spindles and K-complexes were determined and spectral analysis was performed. In addition, we used flurazepame as a tool to modify the sleep of the patients in a second night.

Results: On visual evaluation, occurence of sleep spindles and - to a lower extent - generation of K-complexes was markedly reduced in patients with opportunistic intracranial infections as well as in those with subacute HIV encephalitis. These alterations are indicative for sleep instability. Deep sleep (stage 3 and 4) and REM sleep were markedly shortend. Vegetative phenomena (e.g. heart rate) in sleep did not show the physiological patterns. Among others, these results allow an objective and quantitative description of the AIDS-related destruction of sleep architecture. Following the application of flurazepame, a sixfold increase of sleep spindle density was observed. This finding seems to support the concept of a functional deficit in contrast to the model of circumscript destruction.

Conclusion: AIDS-patients frequently present with complains of poor sleep. Various electrophysiological correlates of this disturbance can be observed. The altered sleep of AIDS patients seems to be due to HIV encephalitis. It might be seen in patients with AIDS-related dementia with or without opportunistic or neoplastic mass lesions.

Th.B.P.275 COMPARISON OF EEG- FINDINGS IN HIV- INFECTED AND NON-INFECTED PATIENTS IN OUT- PATIENT AND IN- PATIENT FOLLOW-UPS

SCHNURBUS,RALF *;KÖNNEKE,J.**;SCHEULER,W.**;KUBICKI,ST.**;HENKES,H.***;GIRKE,W.*;BIENZLE,U.****.
DEPTS.OF *NEUROLOGY,**NEUROPHYSIOLOGY AND ***RADIOLOGY KLINIKUM RUDOLF VIRCHOW, FREE UNIVERSITY ; ****INSTITUTE FOR TROPICAL MEDICINE, BERLIN, FRG.

Objective. The EEG- study evaluates differences in prevalence of cerebral dysfunction between HIV- infected patients and HIV- seronegative volunteers.
Methods.We investigated 541 EEG- recordings of 229 volunteers and patients (48 seroneg.,66 seropos.,58 LAS/ARC, 57 AIDS). Background- activity, hyperventilation- index, occurence of diffuse or focal cerebral dysfunction, vigilance disturbances and paroxysmal patterns were determined.
Results. In age- paired comparisons the decrease in background- activity was significantly higher with in- patients.Out- patient/ in- patient comparisons showed a significant increase in the appearence of diffuse cerebral dysfunction and vigilance disturbances with in- patients. Significant differences in focal cerebral dysfunction and paroxysmal patterns could only be demonstrated in the age- paired comparisons of seroneg./AIDS and LAS/AIDS patients.
Conclusion. The results confirm the dependence of the developing diffuse CNS- dysfunction not only from the clinical stage but also from the severity of the HIV- infection.

Th.B.P.276 QUANTITATIVE VIBRATION THRESHOLD TESTING (QVTT) AND COMPUTER-BASED NEUROBEHAVIORAL TESTING (NES) OF PERSONS INFECTED WITH HIV

Franzblau, Alfred; Letz, R.E.; Hershman, D.; Mason, P.; Wallace, J. and Bekesi, J.G.
Mount Sinai Medical Center, NY, USA 10029

OBJECTIVES: To compare neurobehavioral performance (NES) and vibrotactile thresholds (QVTT) among homosexual men at various stages of HIV infection (N=HIV(-), n=13; P=Asymptomatic HIV(+), n=29; A=ARC/AIDS, n=16); to assess change in neurologic performance over time; to learn how QVTT and NES can be applied to study persons with HIV infection. METHODS: Standardized questionnaire; QVTT applied to index fingers and great toes; NES, including mood scales and 8 performance tests; total lymphocytes, CD4+ lymphocytes (helper T-cells), and serologic markers of HIV. RESULTS: Fifty-eight persons have entered this study for multiple testing. At this time we report only results of the first cycle. The three groups did not differ in mean age (N=40.1; P=41.9; A=38.5), number of years of education (N=15.9; P=15.5; A=15.2), or vocabulary scores (N=19.8; P=20.1; A=20.0; maximum possible=25). Mean absolute numbers of helper T-cells were N=821, P=424, A=112 (N>P>A, $p<.001$ paired analyses). Employment status at time of testing: N=12/13; P=27/29; A=13/16. History of AZT use: N=0/13; P=6/29; A=14/16. Group scores did not differ significantly on any mood scale. Scores of asymptomatic HIV(+) and HIV(-) men did not differ significantly. On the other hand, vibratory thresholds of ARC/AIDS patients were significantly elevated compared to the combined asymptomatic HIV(+)/HIV(-) group (two-tailed t-test, $p<.02$ each digit). Although ARC/AIDS patients were significantly worse on grooved pegboard (non-preferred hand) compared to the combined asymptomatic HIV(+)/HIV(-) group, group means did not differ significantly on any other neurobehavioral test. The frequency of abnormal individual neurobehavioral test scores (at least 1.65 standard deviations below mean) in this sample was low with a slight (nonsignificant) trend toward being greater among asymptomatic HIV(+) and ARC/AIDS patients compared to HIV(-) homosexual men. There were no significant correlations between absolute lymphocyte count or absolute number of helper T-cells and vibrotactile thresholds or neurobehavioral test results. CONCLUSIONS: Within this homogeneous cohort of very functional homosexual men, there were no differences between group means of HIV(-) and asymptomatic HIV(+) men; ARC/AIDS patients performed somewhat more poorly, particularly on vibrotactile thresholds. Absolute number of lymphocytes and helper T-cells had no relationship to measures of neurologic function. The test systems employed in this pilot study are quantitative, rapid, non-invasive, and non-aversive, and therefore appear useful for prospective study of neurologic/neuropsychologic function among persons infected with HIV.

Th.B.P.277 NEUROTOXICITY BATTERY FOR PHASE I HIV DRUG ASSESSMENT: INITIAL APPLICATIONS

Parker, Elizabeth*, Bridge, T.P.**, Ingraham, L.**, Eaton, E.***, and Heseltine, P.N.R.***
*Center for Neuropsychology, Irvine, CA., **National Institute of Mental Health, Bethesda, MD., **University of Southern California, Los Angeles, CA., U.S.A.

Objective. To evaluate the ability of a battery of standard neuropsychologic tests with multiple forms and population norms to detect neurotoxicity in Phase I anti-HIV studies.
Methods. Administration of this battery of tests is made every two weeks following baseline assessment and training to optimal performance. Up to 8 repeat administrations of this battery are possible. Domains assessed are those shown to be affected by HIV infection including memory, attention, mood, motor speed, and cognitive processing efficiency.
Results. This battery for Phase I studies of anti-HIV drugs for HIV patients and matched controls is sensitive to neurotoxicity (3 S.D. decrement on 1/10 tests or 1.5 S.D. decrement on 3/10 tests) or drug effects (up to 3 S.D. increments). Results are presented by standardized norms and by individual and group variation from baseline scores.
Conclusion. Repeat neurotoxicity testing with standard neuropsychologic tests in combination with clinical evaluation demonstrates sensitivity to HIV infection and drug effects without being burdensome to patients or research resources.

Th.B.P.278 COGNITIVE ABNORMALITIES AS A FUNCTION OF HIV-1 CLINICAL STATUS AND USE OF AZIDOTHYMIDINE (AZT): THE MULTICENTER AIDS COHORT STUDY (MACS)

Miller Eric N*, Selnes OA**, Cohen B***, Becker J****, Park L**, Visscher B*, et al. *University of California, Los Angeles, **Johns Hopkins Medical Institutions, ***Northwestern University, ****University of Pittsburgh, Pittsburgh, PA, U.S.A.

Objectives: To characterize early HIV-1 related cognitive abnormalities and to identify neuropsychological measures sensitive to these cognitive changes.
Methods: A sample of 86 HIV-1 seropositive homosexual/bisexual men with diagnoses of AIDS as of December 1988 were matched on age, education and MACS center with subsamples of 86 asymptomatic seropositive men (ASP) and 86 seronegative men (SN). All subjects had completed a brief battery of neuropsychological (NP) tests including WAIS-R Digit Span, Symbol Digit Substitution, Rey Auditory Verbal Learning Test, Grooved Pegboard Test, and Verbal Fluency. Of the 86 subjects with current diagnoses of AIDS, 54 had not yet been diagnosed with AIDS at the time of their initial NP assessment (pre-AIDS group). Of the 32 subjects with AIDS at the time of their NP assessment, 19 were taking AZT.
Results: The five subject groups (SN, ASP, pre-AIDS, AIDS with AZT, AIDS without AZT) were compared using multivariate analysis of variance. There were significant group differences on the Symbol Digit Test ($p < .02$) with subjects in the AIDS subgroups performing more poorly than SN subjects. Post-hoc ANOVA comparing SN controls with each of the four seropositive subgroups revealed significantly poorer performance for subjects with diagnoses of AIDS (with AZT, $p < .02$; without AZT, $p < .02$) relative to the SN group on the Symbol Digit Test. No significant differences were found between the SN group and either the ASP or pre-AIDS groups on the Symbol Digit Test. AIDS patients taking AZT performed slightly better on this task than AIDS patients not taking AZT. We are currently analyzing for effects of self-reported depression.

	Seronegative	Asymp Seropos	Pre-AIDS	AIDS with AZT	AIDS without AZT
Symbol Digit	57.65 (n=86)	55.45 (n=86)	54.99 (n=54)	52.29 (n=19)	49.54 (n=13)

Conclusions: These data suggest that the Symbol Digit test, a measure of psychomotor functioning, is particularly sensitive to cognitive changes associated with HIV infection, although significantly poorer performance on this measure was found only following diagnosis of AIDS.

Th.B.P.279 DECISION-MAKING SPEED IN EARLY HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION

Martin, E., Edelstein, Howard, Robertson, L.
University of California Medical School, Davis, CA, and Veterans Administration Medical Center, Martinez, CA, USA

Objective. To investigate signs of cognitive slowing in early-stage HIV infection by measuring decision-making speed in AIDS-Related Complex (ARC) and HIV-positive asymptomatic (Asx) patients.
Methods. In an ongoing study, 12 patients with early HIV infection (4 Asx and 8 ARC) and 9 controls performed computerized simple and choice reaction time tasks. They were also given a measure of rate of encoding as a control task.
Results. Analysis of obtained reaction times indicated that, as predicted, groups did not differ in speed of simple reaction time. However, ARC patients were significantly slower than controls in speed of choice reaction time. Mean choice reaction times for Asx patients were in the predicted direction (e.g., slower than controls) but this difference fell short of statistical significance. There were no significant group differences on the control task.
Conclusions. Cognitive slowing is a prominent clinical characteristic of AIDS dementia. In the current study, subtle cognitive slowing (increased decision-making time) was demonstrated in individuals with less advanced disease. Cognitive abnormalities in patients with early HIV infection have not been demonstrated reliably on standard clinical neuropsychologic tests in previous studies. Our data indicate that reaction time-based procedures may provide a more reliable and sensitive measure of cognitive dysfunction than other standard clinical tests in this population.

Th.B.P.280 ABNORMALITIES OF EEG AND OTONEUROLOGIC TESTS IN ASYMPTOMATIC HIV INFECTED HOMOSEXUALS : A PROSPECTIVE CONTROLLED STUDY.

Koralnik Igor, Beaumanoir A., Häusler R., Kohler A, Delacoux R., Hirschel B. et al.
Geneva University Hospital, 1211 Geneva, Switzerland. Phone 41 22 22 64 16.

Objective : To study the earliest neurologic manifestations in HIV1 infected individuals (CDC group 2 and 3).
Methods : After exclusion of any use of i.-v. or psychotropic drugs, and of prior neuropsychiatric illness, 25 HIV seropositive asymptomatic homosexuals and 30 seronegative homosexuals volunteered to participate in this study. It included neurologic and neuropsychologic evaluation, MRI, EEG, multimodal evoked potentials (pattern visual(P-VEP), somatosensory (SEP) and brainstem auditory (BAEP)), and otoneurologic tests (audiogram, impedance measurement, binaural lateralization test, electronystagmogram). The investigators were blinded to the serologic results.
Results : Seropositives (Ps) and controls (Cs) were closely matched with regard to age and education. As expected, Ps were more likely to have serologic evidence for syphilis (60%) than Cs (33%),($p = .026$). Likewise, the mean CD4 count was 628 for Ps and 1059 for Cs. ($p = .002$). Neurologic and neuropsychologic examinations and MRI failed to show any significant differences between the 2 groups. Increased P-VEP and SEP latencies were found in two different HIV positive individuals. The otoneurologic evaluation was pathologic in 8 (32%) Ps and in 1 (3%) C ($p = .017$). EEG was abnormal in 11 (44%) Ps and 3 (10%) Cs ($p = .028$), showing diffuse theta waves and reactivity abnormalities. Altogether, electrophysiologic abormalities were found in 60% of P and only 13% of C ($p = .012$).
Conclusion : This study suggests that electrophysiologic tests may be the most sensitive indicators of subclinical neurologic manifestations in HIV infected individuals. Results from the first follow-up examination will be presented.

Th.B.P.281 EEG FINDINGS AND COGNITIVE PERFORMANCE IN 82 HIV- INFECTED PATIENTS.

Parisi, A.**; Bono, G.*; Sinforiani, E*; Turla, M.*; Minoli, Lorenzo** and Nappi, G.*
*3rd Dept.of Neurology, IRCCS C.Mondino and **Dept.of Infectious Disease, IRCCS Policlinico S.Matteo, University of Pavia, 27100 Pavia, Italy.

Aims.To detect subclinical/clinical changes in the mental performance of HIV-infected patients; to correlate eventual neuropsycological damage with the EEG findings; to evaluate the occurrence of the above alterations in the same subjects.
Methods.N.82 patients (CDC group II: n. 23; II: 30; IV A: 10;IV B: 6; IV D-E: 13) were selected based on the absence (neuroimmaging and laboratory exams) of focal/diffuse CNS pathology due to tumors, opportunistic infections and/or other conditions complicating AIDS. A set of n. 14 neuropsychological test exploring short/long-term memory (verbal and non-verbal), language and visuoperceptive functions were administered, together with standard EEG recordings.
Results.Neuropsychological and EEG abnormalities were found with increasing degrees of frequency/severity from group II to groups IV: long-term memory, attention, logic abilities, were the mostly affected functions. Correlation coefficients were calculated for the total population and each diagnostic group: significant values ($p<0.05$) were obtained, particularly for groups III and IV. For these patients, the concomitant evidence of EEG and neuropsicholpgical abnormalities, in absence other demonstrable CNS disease, may indicate "early-possible" AIDS-dementia complex.

Th.B.P.282 ETUDE EN IMAGERIE PAR RESONNANCE MAGNETIQUE NUCLEAIRE (IRM) ET CORRELATION ANATOMOCLINIQUE, LORS D'ATTEINTES NEUROLOGIQUES DU SIDA.

Brion J.P.°, Leclercq P°, Stahl J.P.°, Micoud M°, Lebas J.F.°°, Tomasi M°°
Centre Hospitalier Régional Grenoble°, Hôpital Neurologique - Lyon°° - France

Objectif : Il s'agit d'une corrélation anatomoclinique entre Tomodensitométrie* IRM** et IRM sur cerveaux fixés par le formol, chez 12 patients décédés de SIDA et présentant des signes neurologiques.
Méthode : Pour chaque malade, a été réalisé un examen neurologique complet et répété, associé à une évaluation biologique et immunologique. Une TDM avec injection iodée a été pratiquée dans tous les cas, et dans 4 cas une IRM réalisée du vivant du malade. L'encéphale a été prélevé et fixé dans le formol à 10 %. L'étude en IRM a été effectuée en coupes axiales jointives de 9 mm. L'examen neuropathologique a été effectué selon les plans de coupes de l'IRM et l'étude histologique en microscopie photonique.
Résultats : - 3 patients présentaient une encéphalite à cellules géantes avec TDM non significative et hyposignal de la substance blanche en IRM., - L'IRM a décelé un cryptococome bilatéral des noyaux gris dans 1 cas, - 2 patients ont présenté un accident vasculaire cérébral, - Dans 3 cas, seule l'histologie a permis un diagnostic (toxoplasmose, granulome à mycobactérie et leucoencéphalite débutante), - Chez 3 patients, atteints de Sarcome de Kaposi disséminé, il n'y avait pas d'atteinte encéphalique.
Conclusion : Dans 5 cas sur 9, le TDM n'a pas décelé de lésion alors que dans 8 cas sur 9, l'IRM a mis en évidence des anomalies évocatrices. Par ailleurs, l'IRM représente un examen de choix pour l'exploration de la substance blanche et le diagnostic des atteintes encéphaliques du SIDA.
* TDM ND8000 Thomson CGR - ** IRM : Magniscan 500 Thomson CGR

Th.B.P.283 PROSPECTIVE EVALUATION OF AN ALGORITHM FOR THE DIAGNOSIS OF AIDS-RELATED NEUROLOGIC ILLNESS: EXPERIENCE WITH OVER 200 PATIENTS

Levy, Robert; Grohmann, S.; Cohen, B.; Von Roenn, J. and Murphy, R.
Northwestern University Medical School, Chicago, IL USA

Algorithms for the diagnosis of neurologically symptomatic HIV infected patients have been based upon retrospective experience. To prospectively evaluate one such algorithm, we have applied it to all HIV infected patients at our institution. From September 1987 to December 1988, 205 such patients were evaluated; 58 (28%) were neurologically symptomatic. These patients underwent cranial MRI or double dose contrast enhanced cranial CT scans. Patients with multiple intracranial lesions, if neurologically stable and alert or only mildly lethargic, were treated empirically for toxoplasmosis. If either the followup MRI or the clinical examination were not improved by this therapy, or if patients deteriorated during the empiric trial, CT guided stereotactic brain biopsy was performed. In patients with solitary MRI lesions or in those who were stuporous or comatose, emergent biopsy was performed without an empiric trial of therapy. Ten patients underwent 11 CT-guided stereotactic brain biopsies. Thus, 4.9% of our overall population underwent biopsy; this agrees well with the projected rate of 6.8%. There was one hemorrhagic complication which resulted in unilateral facial weakness (11% morbidity; 0% mortality). Of the 10 patients undergoing biopsy, 3 had toxoplasmosis, 3 had PML, 2 had primary CNS lymphoma, and 2 had HIV encephalitis. The 3 patients with PML are dead (mean survival 2.3 months). Both patients with lymphoma died prior to completing radiation therapy. One patient with refractory toxoplasmosis died, the other 2 are alive and well, following changes in their medical regimens, 13 and 16 months after biopsy. One patient with HIV-1 encephalitis is stable 2 months after biopsy, the other died 4 months after biopsy. Based upon this early prospective experience, this then appears to be a logistically feasible and effective algorithm for the diagnosis of AIDS patients with neurological illness.

Th.B.P.284 PATTERNS OF NEUROPSYCHOLOGICAL DYSFUNCTION IN A SELECT GROUP OF HIV+ INDIVIDUALS IN COMPARISON TO PSYCHIATRIC CONTROLS

Martin, Alex; Salazar, A.M.; Kampen, D.; Williams, J.; Law, W.; Gomez, C.; & Walter Reed Retrovirus Research Group.
Uniformed Services University of the Health Sciences & Henry M. Jackson Foundation, Bethesda, Maryland; Walter Reed Army Medical Center, Washington, DC, USA.

Objective. To investigate the nature of cognitive impairment in HIV+ individuals, either complaining of, or suspected of cognitive dysfunction.
Methods. Fifty (50) HIV+ and 15 seronegative patients with adjustment disorders (ADJ DIS) were tested on a battery of 40 standard and experimental tasks assessing different types of attention, motor, memory, language, perceptual, and problem solving abilities. Patients were classified in Walter Reed Stages 1-5; the majority had persistent lymphadenopathy (WR-2, 52%); 84% were in WR Stages 1-3. The ADJ DIS patients were matched with the HIV+ group on education, depression, anxiety, types of cognitive complaint, and number of recent stressful life events. Results. Based on predetermined cut-off scores, 48% of the HIV+, but only 7% of the ADJ DIS, patients were impaired on >10 of 51 measures derived from the battery. Twenty-four percent (24%) of HIV+, but none of the ADJ DIS were impaired on >20 measures. Although heterogeneous with regard to type of cognitive impairment, the most common difficulties were on tasks of attention span, visuomotor dexterity, spatial functions, word knowledge, and new learning. No group differences were observed on measures of visual perception, fluency, or concept formation and problem solving. Overall, neither extent nor type of deficit was significantly related to history of risk factors, anxiety, depression, total T_4, T_8, or T_4:T_8 ratio.
Conclusions. Although not addressing the prevalence of cognitive dysfunction, these data do indicate that a variety of deficits can occur in relatively asymptomatic HIV+ individuals that cannot be attributed to current mood state. These findings highlight the need for longitudinal study of an unselected sample.

Th.B.P.285 CURRENT PERCEPTION THRESHOLD IN HIV-POSITIVE PATIENTS

Katims, Jefferson J.*; Taylor, D.N.**; Wallace, J.I.***, ****; Bekesi, J.G.**** and Masdeu, J.C.***, New York, N.Y.
*Cabrini Medical Center, **City Univ. of New York, ***St. Vincent's Medical Center of New York, and ****Mount Sinai School of Medicine, New York, U.S.A.

Objective. To evaluate perception of nerve stimuli in neurologically asymptomatic HIV-positive individuals.
Methods. Using a sine-wave transcutaneous stimulator, current perception thresholds and habituation at various frequencies were determined from 17 asymptomatic HIV-positive individuals, 12 patients with ARC and 10 with AIDS, all free of sensory symptoms (ages 29-62, median = 36). HIV status was unknown to the examiner. Following previously described painless, non-invasive procedures *(Katims J et al., Arch Phys Med Rehab 1987;68:210; Appl Neurophysiol 1986; 49:86)*, peroneal, median and trigeminal nerves were tested bilaterally, in a double-blind forced-choice paradigm of 20 minutes duration.
Results. Eighty-two percent of all subjects had measures that differed ($p<0.05$) from age-matched controls. Trigeminal perception impairment correlated with severity as determined by CDC classification ($r=.56$, $p< 0.001$) which correlated with total T4 cell count ($r=.54$, $p< 0.001$). Inability to maintain trigeminal perception was only observed in the ARC (33%) and AIDS (60%) subgroups.
Conclusion. Perception abnormalities were detected in a high percentage of neurologically asymptomatic HIV-positive individuals. The inability to maintain sensory perception of trigeminal stimuli was characteristic of the more advanced stages and may reflect a deficit of attentional mechanisms. Current perception determination is a sensitive test for the evaluation of the sensory system in HIV-positive individuals.

Th.B.P.286 NEUROPSYCHOLOGICAL EVIDENCE FOR EARLY INVOLVEMENT OF THE BASAL GANGLIA REGION IN A SUBGROUP OF HIV+ INDIVIDUALS

Martin, Alex; Kampen, D.; Salazar, A.M.; Williams, J.; Law, W.; Roller, T.; & Walter Reed Retrovirus Research Group.
Uniformed Services University of the Health Sciences & Henry M. Jackson Foundation, Bethesda, Maryland; Walter Reed Army Medical Center, Washington, DC, USA.

Objective. To investigate the performance of HIV+ individuals on procedural or skill learning (SL) and egocentric spatial (ES) tasks. Previous findings suggest that performance on these types of tasks is disrupted by involvement of basal ganglia region. For example, both Huntington's (HD) & Parkinson's (PD) patients show impaired skill learning, while amnestic patients do not. Similarly, HD & PD patients show impaired egocentric spatial ability, while patients with parietal lesions or early Alzheimer's disease do not. Methods. Fifty HIV+ individuals referred for neuropsychological testing and 15 seronegative patients with adjustment disorders (ADJ DIS) were tested on an SL task requiring solving the same visual maze presented three times at 20 minute intervals. Egocentric spatial ability was tested using Money's Road-Map Test of Direction Sense, and a newly devised experimental procedure; the Room Test. Patients were classified in Walter Reed Stages 1-5; the majority had persistent lymphadenopathy (WR-2, 52%); 84% were in WR Stages 1-3. The ADJ DIS patients were matched with the HIV+ group on education, depression, anxiety, and number of recent stressful life events. Results. The HIV+ patients were significantly slower, but not less accurate, than controls on all Maze trials. A subgroup of patients (N=28) performed as fast as controls on the initial trial, but exhibited significantly less learning than controls over the remaining trials ($p<.01$). The patients also performed worse than controls on both measures of ES ability ($p=.01$, $p<.05$, for the Road-Map & Room tests, respectively). Performance on these measures was highly correlated($p<.001$). Conclusions. At least some relatively asymptomatic HIV+ individuals exhibit a pattern of cognitive difficulties suggestive of early involvement of the basal ganglia or nigrostriatal system.

Th.B.P.287 PROSPECTIVE NEUROLOGICAL AND NEUROPHYSIOLOGICAL ASSESSMENT IN A COHORT OF HOMOSEXUAL MEN.

McAllister RH, Harrison MJG, Griffin GB, Fowler CJ, Newman SP, Herns MV, Weller IVD.
UNIVERSITY COLLEGE & MIDDLESEX SCHOOL OF MEDICINE, LONDON UK. W1N 8AA.

Objective: To evaluate neurophysiological abnormalities as markers of sub-clinical neurological disease in HIV infection.
Methods: 117 gay men participating in the Medical Research Council Cohort Study of the natural history of HIV infection underwent standard neurological history & examination, lower limb nerve conduction studies & somatosensory evoked potentials (SEPs). Those with pre-existing neurological disease or CDC Group IV HIV disease were excluded. 74 HIV seropositive (SP) and 32 seronegative (SN) men were eligible. Neurophysiological results were compared using analysis of variance with age & height as covariates.
Results: SP men were significantly more likely to complain of problems with memory (chi-square, $p = 0.04$) and concentration ($p = 0.08$) but did not otherwise differ from SN men on history, examination, mean sensory or motor action potential amplitudes or conduction velocities, 'f' wave latencies, or vibration perception thresholds in the lower limb. Lower limb SEP latencies were consistently and, on the left, significantly longer in the SP group (ANOVA, $p = 0.01 - p = 0.05$). Differences observed between left and right may have been due to order effects.
Conclusion: Asymptomatic SP men appear to have prolonged lower limb SEP latencies compared with a well - matched SN group. Slowing of peripheral nerve conduction does not account for the difference.

Th.B.P.288 CHANGES IN PERFORMANCE ON THE TRAIL-MAKING TEST BEFORE AND AFTER HIV-1 SEROCONVERSION AND DIAGNOSIS OF AIDS: THE MULTICENTER AIDS COHORT STUDY (MACS)

Miller Eric N*, Selnes OA**, Visscher B***, McArthur JC**, Satz P*, Dudley J***. *University of California, Los Angeles, **Johns Hopkins Medical Institutions, ***UCLA School of Public Health, U.S.A

Objectives. To examine longitudinal performance on the Trail-Making Test for HIV-1 seronegative, asymptomatic prevalent and incident seropositive, and symptomatic seropositive (AIDS) homosexual/bisexual men in the Multicenter AIDS Cohort Study (MACS).
Methods. A cohort of 551 HIV-1 seronegative, 441 asymptomatic prevalent seropositive (seropositive since 1984), 73 asymptomatic incident seropositive (seroconversion between 1984 and 1988), and 113 symptomatic seropositive (confirmed diagnoses of AIDS) homosexual/bisexual men from the Los Angeles and Baltimore cohorts of the MACS were administered Part B of the Trail-Making Test semi-annually from 1986 to 1988. This task correlates highly with other neuropsychological measures including Verbal Fluency, Symbol Digit, and Digit Span, and is considered one of the most sensitive for detecting HIV-related cognitive decline.
Results. Performance on the Trail-Making Test was adjusted for the effects of age, education and repeated administration using multivariate analysis of covariance. We found no differences between the seronegative and asymptomatic seropositive groups on this task across any of the 6 semi-annual testing intervals. Similar results were obtained comparing HIV-1 seroconverters with age- and education-matched seronegative controls, with no significant differences found between these groups for up to 1 year prior to seroconversion through 2 years following seroconversion. Longitudinal comparison of subjects with diagnoses of AIDS and age- and education-matched seronegative controls showed a trend toward steadily declining performance on the Trail-Making Test from 6-months prior to a diagnosis of AIDS through 1.5 years following an AIDS diagnosis, although this difference was statistically significant only 1.5 years following initial diagnosis. We are currently analyzing these data for effects of AZT use.
Conclusions. These findings suggest that HIV-related abnormalities on the Trail-Making Test become evident only following initial AIDS diagnosis. We observed no evidence of gradual decline on this measure among otherwise asymptomatic seropositive subjects. These data support previous cross-sectional data from the MACS suggesting no increased risk for cognitive abnormalities among asymptomatic seropositive individuals.

Th.B.P.289 NEUROPSYCHOLOGICAL PERFORMANCE IN HIV-1 IMMUNOCOMPROMISED PATIENTS

Van Gorp, W.* **; Miller, E.**; Satz, P.**; and Visscher, B.** *West Los Angeles Veteran's Administration Medical Center **UCLA School of Medicine, U.S.A.

Objective. To examine the pattern of neuropsychologic performance in 3 subject groups: AIDS, ARC and seronegative gay males.
Methods. Twenty patients with AIDS, 14 with ARC and 13 seronegative gay male controls were administered a comprehensive neuropsychologic test battery. Subjects with a past history of chronic substance abuse, neurologic disease or focal findings on CT or MRI were excluded.
Results. The AIDS group performed significantly more poorly (p.<.002) or showed a trend (p.<.01) toward poorer performance than the ARC and seronegative groups on one speeded and one non-speeded measure of visuoconstructional skills (Block Design; Picture Completion), all measures of motor speed and cognitive flexibility (Digit Symbol, Trailmaking Test A/B), and all measures of nonverbal memory (Visual Reproductions, Rey Osterrieth delayed recall). The groups did not differ on any measure of attention, language, verbal memory or Mini-Mental State Examination (MMSE) scores.
Conclusion. Tests involving psychomotor speed, cognitive flexibility and nonverbal memory appear most sensitive to early disruption in progressive stages of HIV-1 related immunocompromise, presumably related to central nervous system involvement. The MMSE scores were uniformly high and in the non-impaired range (>23) for our immunocompromised subjects. This is consistent with observations that the MMSE is not sensitive to mental status abnormalities in this population until later or end stage dementia is present.

Th.B.P.290 ANTISACCADIC EYE MOVEMENT ABNORMALITIES IN ASYMPTOMATIC HIV SEROPOSITIVE INDIVIDUALS

Currie, Jon (1,2); Ramsden, BM; Lynch, JM; McArthur, CL. Benson, EM; Perdices, M et al.
(1) Mental Health Research Institute of Victoria, Melbourne, Australia; (2) Save Sight and Eye Health Research Institute, Sydney; AUSTRALIA

Objectives: to determine whether antisaccadic eye movements are of clinical use in detecting the early onset of neurological dysfunction in asymptomatic HIV seropositive (HIV+) subjects.
Methods: we used high resolution infrared oculography and an eye movement test battery that included an antisaccadic paradigm. Subject groups included homosexual HIV seronegative (HIV-) and heterosexual HIV- controls, asymptomatic HIV+ subjects, neurologically intact AIDS patients and patients with cortical or subcortical dementia.
Results: In asymptomatic HIV+ subjects, pro-saccades, smooth pursuit and antisaccadic accuracy did not differ significantly from controls. However, antisaccadic latencies were significantly prolonged in 38% of asymptomatic HIV+ subjects (p<0.01), suggesting a subtle impairment of frontal lobe ocularmotor programming.
Conclusions: The antisaccadic eye movement paradigm is a valuable, rapid and non-invasive technique for the early detection of neurologic dysfunction in non-demented AIDS patients and in asymptomatic HIV+ subjects. In particular, it may be of use in selecting high risk patients requiring antiviral therapy, in quantitatively monitoring neurologic disease or response to therapy and in providing reassurance to well subjects by helping to differentiate affective disturbance from early dementia.

Th.B.P.291 SEQUENTIAL AUTONOMIC FUNCTION TESTS IN HIV INFECTION

Scott, Gordon*; Piaggesi, A**; Ewing, D J**.

*Dept. of G-U Medicine, Edinburgh Royal Infirmary, Edinburgh, Scotland.
**Dept. of Medicine, Edinburgh University, Edinburgh, UNITED KINGDOM.

Objective. To determine whether progressive abnormality of autonomic function on sequential testing might act as a prognostic indicator in HIV infection.
Methods. 20 men with varying stages of HIV infection were studied (13 CDC group II/III, 7 CDC group IV). Standard haematological and immunological indices were recorded. The following standard autonomic function tests were carried out:- heart rate response during the Valsalva manoeuvre, lying to standing, and deep breathing; and the blood pressure responses to standing up and sustained handgrip. 14 of these patients also underwent 24 hour monitoring for measurement of heart rate variation.
Results. The mean T4 lymphocyte count of the group was 545, and the mean serum IgA was 3.25g/l. Only one patient showed significant abnormality of autonomic function. In those in whom the tests were repeated one year later, although there was evidence of progression of HIV-associated disease in that the mean T4 count had fallen to 370 and the mean IgA level had risen to 4.9, there was no significant alteration in autonomic function.
Conclusion. Significant changes in autonomic function that might act as a prognostic indicator in HIV infection do not seem to develop during this time span.

Th.B.P.292 Neuro-Performance Measurement and Memory Profiles of Disability in HIV Seropositive Individuals

K. Syndulko, E. Singer, P. Ruane, B. Fahy-Chandon, G. Kondraske*, Wallace. W. Tourtellotte
Neurology Service, VAMC W. Los Angeles, CA 90073, Dept. Neurology, UCLA School of Medicine. 213 824-4307, and *Depts. of Electrical and Biomedical Engineering, University of Texas at Arlington, Arlington, TX, U.S.A.

Objective:: To examine HIV related central nervous system (CNS) changes as a function of systemic indices of HIV disease progression.
Method: 93 HIV infected individuals without CNS opportunistic infections/tumors were categorized as systemically Asymptomatic Seropositive (ASP, n=53), ARC (n=34) or AIDS (n=6), and were tested on a battery of 43 computerized memory and motor neuro-performance (NP) tests (including right and left limbs separately).
Results: Decreased memory for name/face associations and first/last names, decreased upper extremity (speed, simple and 2-choice reaction time [RT], tracking, and dexterity) and lower extremity performance (speed, simple RT and standing balance) were significantly (p<0.01) associated HIV disease category (ASP vs. ARC/AIDS). In addition, for patients with HIV related neurologic signs/symptoms, tests of memory for spatial position of objects, telephone numbers, and facts showed concordant statistically significant (p<0.01) worsening compared to those without neurologic signs and symptoms Subgroups showing performance deficits also showed increased anxiety, depression and other indices of psychological distress.
Conclusions: In support of previous studies, there is an objective profile of neuro-behavioral changes in HIV seropositive individuals that includes increased anxiety and depression, motor slowing, decreased dexterity, impaired balance and memory deficits and that is modestly related to clinically defined decreasing immune competence even in the absence of AIDS and CNS opportunistic infections.

Th.B.P.293 Latency of P300 and Pattern Visual Evoked Potential Are Not Sensitive to Early HIV Related Neurologic Disease.

K. Syndulko, E. Singer, P. Ruane, B. Fahy-Chandon, Wallace. W. Tourtellotte.
Neurology Service, VAMC W. Los Angeles, CA 90073, Dept. Neurology, UCLA School of Medicine,
Los Angeles, CA, U.S.A.

Objective: To use patterned visual evoked potentials (PVEP) and P300 for the evaluation of neurophysiological changes associated with HIV infection
Method: 70 HIV sero-positive individuals without CNS opportunistic infections or tumors were categorized clinically as systemically asymptomatic (ASP, n=32), ARC (n=32) or AIDS (n=6) at the baseline of a longitudinal study to examine CNS changes as a function of several systemic indices of HIV disease progression (HIV medical classification, blood T-cell subsets, blood HIV cultures and HIV antigens) All individuals were also categorized as Neuropositive and Neuronegative (with and without HIV related neurologic signs and symptoms, respectively). Two classes of ERPs were obtained using standard recording procedures: 1) PVEP for each eye separately using video generated 30' checks reversed at 2/sec; and 2) the P300 component of the auditory ERP in a standard tone-pip target detection task.
Results: PVEP showed no significant changes with HIV disease category or with neurologic status. P300 latency was not related to decreasing immunological status (T4 helper cell numbers or HIV disease category) nor to the presence of HIV related neurologic signs and symptoms. In contrast to previous results for Alzheimer Disease and cognitive declines in Parkinson disease, HIV seropositive individuals who were clinically classified as moderately to severely cognitively impaired (n=5), i.e. "AIDS Dementia Complex", did not show significantly longer P300 latencies than normal controls.
Warranted Conclusions: The data suggest that the CNS changes in HIV neuro-disease are qualitatively different than those seen in Alzheimer disease and the dementia associated with Parkinson Disease. In addition, there was no evidence for conduction deficits along the optic pathways in HIV related neurologic disease.

Th.B.P.294 COMPUTERIZED SCREENING FOR HIV-RELATED COGNITIVE DECLINE: CROSS-SECTIONAL ANALYSES AND ONE-YEAR FOLLOW-UP

Miller Eric N*, Satz P*, Van Gorp W*, Visscher B**, Dudley J**.
*University of California, Los Angeles, **UCLA School of Public Health, Los Angeles, CA, U.S.A.

Objectives. To standardize and validate a computerized neuropsychological (NP) screening battery for early detection of cognitive decline in HIV-infected individuals.
Methods. A cohort of 171 HIV-1 seronegative (SN), 128 asymptomatic seropositive (ASP), and 28 symptomatic seropositive (ARC or AIDS) gay men from the Los Angeles cohort of the Multicenter AIDS Cohort Study were administered a computerized reaction time battery together with a conventional neuropsychological screening battery on three occasions over the course of 1 1/2 years. Both of the screening batteries were designed to assess cognitive domains representative of NP deficits found in HIV-related encephalopathy, including motor speed and divided attentional skills. Subjects were designated as 'outliers' on both sets of measures if they scored 2 or more SDs below the mean for SN's on 2 or more measures at any one visit, or if they showed significant decline (1 SD or greater) on 3 or more measures between visits.
Results. There was considerable agreement between the computerized and conventional tasks, with the two sets of measures agreeing on outlier status from 84-87% of the time across the three visits. Both the computerized and conventional screening measures identified approximately the same numbers of SN and ASP men as being outliers at each visit on cross-sectional analyses. A significantly higher proportion of asymptomatic (X^2 = 6.45, p < .02) and symptomatic (X^2 = 6.92, p < .01) SP subjects showed decline on the computerized measures from Visit 1 to Visit 2 than did SN subjects, although this finding was not replicated at one-year follow-up. No such finding was obtained for the conventional NP screening battery either at six-month or one-year follow-up. Discrimination of the SN and SP groups was significantly improved when results from both the computerized and conventional screening measures were taken into consideration.
Conclusions. These findings suggest that computerized techniques may prove practical as a rapid, efficient and inexpensive screening tool for detecting early cognitive decline in HIV-infected individuals, although these measures work best in conjunction with traditional neuropsychological measures. When used longitudinally, this type of measure appears to have slightly greater sensitivity for identifying individuals at risk for HIV-encephalopathy than do conventional neuropsychological screening procedures.

Th.B.P.295 EVENT-RELATED POTENTIAL MEASURES OF DEMENTIA IN HIV DISEASE

Christine Ollo, R. Johnson, Jr., J. Grafman, L. Govoni, D. Rubinow, P. Bridge. National Institute of Mental Health, National Institutes of Health, Bethesda, MD, USA

Objectives It is estimated that 40-70% of HIV-infected patients will develop AIDS dementia complex (ADC). Early cognitive changes in ADC include decreased concentration and cognitive and motor slowing. Event-related potential (ERP) components such as P3 provide a physiological measure of cognitive processing. P3 latency reflects brain changes associated with normal aging and dementia, while amplitude varies with stimulus characteristics and processing demands. ERP assessment of HIV-infected patients may reveal early encephalopathic changes that are not apparent using other techniques.
Methods To date, six control and 13 HIV+ males (4 asymptomatic, 4 ARC, 5 AIDS) without current clinical signs of physical illness or neurological involvement have been tested. A brief neuropsychological battery was given to assess cognition and mood. After audiometric screening, EEG was recorded using gold cup electrodes at FPz, Fz, Cz, Pz and Oz with a sterno-vertebral reference and amplified at a HF cut-off of 60 Hz and a TC of 10 sec. ERPs were recorded for 1150 msec with a 50 msec prestimulus baseline at a sampling rate of 200 Hz. Auditory (50 msec binaural tone pips of 1000 and 1500 Hz) and visual (the letters 'X' and 'O') ERPs were recorded in separate choice reaction time tasks at two levels of probability, 20:80 and 50:50. Only correct response trials free of eye-movement artifact were included in the averages. Peak latencies and baseline-to-peak amplitudes were measured for the early and late ERP components including N200 and P300 in the averaged waveforms.
Results Preliminary data analysis indicates that P300 amplitude was greatly reduced in HIV+ patients including some asymptomatic patients. The amplitude decrement was greatest in response to the rare auditory stimulus at Cz (F=5.14; df 3,17; p<.02). Component latencies were prolonged also; 25-50% of HIV+ patients had latencies exceeding the upper limit of the control subject range in each task.
Discussion The results of this ongoing study show both ERP latency prolongation, more typical in organic disorders, and amplitude reduction which may reflect faulty processing of sensory information and also can occur in psychiatric disorders including depression. The relationship between the ERP variables and cognitive status and mood will be evaluated in the larger sample. The data suggest that ERPs may be useful in clarifying diagnosis by identifying patients with cognitive changes due to degenerative processes from those with depression and provide a tool for assessing disease progression and evaluating treatment outcome.

Th.B.P.296 CLINICAL VALIDATION OF A BEDSIDE ANTISACCADIC TEST FOR THE ASSESSMENT OF AIDS DEMENTIA

Currie, JN. (1); Benson, Elisabeth M.(2); Ramsden, BM.(1); Lynch, JM.(1); McArthur, CL.(1); Cooper, DA. (3)
(1) Mental Health Research Institute of Victoria, Melbourne, Australia; (2) Monash University Medical School, Melbourne, Victoria; (3) NHMRC Special Unit in AIDS, Sydney, New South Wales.AUSTRALIA

Objectives: High resolution eye movement recordings are of value in the early diagnosis and management of the AIDS dementia complex (ADC). However, the equipment used is expensive and requires a laboratory setting. We describe and clinically validate a bedside antisaccadic eye movement test that can be administered by a single examiner and requires no equipment.
Methods: We tested 350 subjects, including both homosexual and heterosexual controls and patients with cortical or subcortical dementias, including ADC. The antisaccadic test was administered over five minutes using a standardised protocol. The % antisaccadic error score and antisaccadic latencies were correlated with Mini-mental status (MMS) and color-form sort (CFS) scores.
Results: 95% of the control population made fewer than 25% errors. Most subjects with clinical dementia made >25% errors. Error scores correlated linearly with MMS and CFS scores, but not with tests of sustained attention or more general arousal.
Conclusion: The bedside antisaccadic test is simple, robust and inexpensive, and correlates with frontal lobe dysfunction. It may be useful in the assessment of ADC, particularly in field studies or population surveys in Third World countries.

Th.B.P.297 MULTIMODALITY EVOKED POTENTIALS IN HIV INFECTED SUBJECTS: A LONGITUDINAL STUDY

Gala,Costanzo *; Ducati, A.**; Donati, R.**; Vianello, L.***; Mansi, M.****; Martini, S.*.
* Institute of Psychiatry, ** Institute of Neurosurgery, *** Transfusional Center, **** Institute of Dermatology, University of Milan, Italy.

Objective: evaluation of cortical function impairment in the early course of HIV infection, by means of multimodality evoked potentials (MEPs).
Methods: 20 HIV infected subjects were studied (16 homosexual males, 2 heterosexual males, two heterosexual females). They were seropositive for at least 6 months before entering the protocol. All subjects underwent a session of MEP recording that included brainstem acoustic evoked potentials (BAEPs), somatosensory evoked potentials (SEPs), pattern reversal visual evoked potentials (PR-VEPs). The same session was repeated between 6 and 8 months after the first one, in the same subjects.
Results: electrophysiological data referring to the first session demonstrated a significant change of cortical responses in more than 50% of subjects. The data of the second recording did not show an increase of the percentage of abnormal results in the same group of subjects, but in 3 patients, whose response were already pathological, a definite worsening was observed.
Conclusion: our results suggest that the involvement of the cerebral cortex takes place early in the course of the HIV infection.

Th.B.P.298 BODY COMPOSITION IN ASYMPTOMATIC HIV-POSITIVE MEN

Gold, J.*; Oliver, C.*; Allen, B.J.**; Blagojevic, N.**; Rose, A.**.
*Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia, **ANSTO Lucas Heights Research Laboratories, Menai, Australia.

Objective. To assess effect of HIV virus on the body composition of Group II or III males.

Methods. Body protein and water compartments are determined from measurements of total body nitrogen, total and extracellular water, and anthropometric data taken at 6 monthly intervals. Prompt neutron activation and tritium, NaBr and 35SO4 dilution techniques are used. The immunocompetence and nutritional status of each subject is obtained from immunological, haematological, biochemical and dietary tests. Subjects are classified according to their staging and any drugs used to control the disease. No effort has been made to control drug intake or lifestyle because of problems relating to compliance.

Results. Intitial relationships between staging and body composition parameters will be presented for the target cohort of 100 subjects.

Key Words. body composition, cachexia, nutrition, neutron activation analysis, diet.

Th.B.P.299 NUTRITIONAL STATUS IN AIDS PATIENTS.

Scevola Daniel, Barbarini G., Zambelli A., Bottari G.
Institute of Infectious Diseases, University of Pavia, ITALY

Objective. To assess the nutritional status of AIDS patients in relation to evolution of disease, incidence rates and type of opportunistic infections.
Methods. We studied nutritional status of a group of HIV infected patients affering to Institute of Infectious Diseases, University of Pavia, Italy, using classic anthropometric methods, immunologic and biochemical parameters. Estimation of body composition (FFM, FAT, TBW) and body mass index was performed by means of a computerized bioelectrical impedance method. Incidence, type and severity of infections were considered in relation to nutritional indices.
Results. We found a clear relationship between physical condition and incidence rate of opportunistic infections in the majority of AIDS patients. The more important nutritional deficits are significantly related to a greater incidence of severe infections.
Conclusion. The nutritional status of the AIDS patients also in western countries appears to be one of the more important determinant for incidence of opportunistic infections and evolution of disease. The supply of sufficient nutrients capable to restore a normal weight is mandatory in this condition and may contribute to enhance host defence against different types of pathogens and prolong the survival of AIDS patients.

Th.B.P.300 LESS DIARRHEA SEEN IN HIV-POSITIVE (HIV+) PATIENTS ON A LOW-FAT, ELEMENTAL DIET (ED)

King, Alison B.*; McMillan, G.**, St. Arnaud, J.**; and Ward, T.T.** *Norwich Eaton Pharmaceuticals, Inc., Norwich, NY, U.S.A., **Portland V.A. Medical Center, Portland, OR, U.S.A.

Objective. Describe effects of a low-fat, low-residue ED (Vivonex T.E.N.) on body weight (WT), bowel movements (BM), and GI symptoms (pain, vomiting, bloating, nausea, and appetite) (GIS) in HIV+ adults who have chronic or intermittent diarrhea.
Methods. In this 2-week prospective, non-randomized, multicenter study, subjects consumed their usual diet during a 2-day (d) baseline period (B), then ED for 10 d, and usual diet again during a 2-d follow-up (FU). WT was measured pre-study, during ED, and post-study. Subjects completed daily diaries recording food, beverage, and ED intake; BM; GIS; medications; and activities. Data on 7 subjects are presented here. This protocol will be extended through at least 40 subjects.
Results. Subjects showed a 65% reduction in mean #BM from 2.6/d during B to 0.9/d during ED. Mean #BM increased to 1.6/d during FU. Five of the 7 subjects maintained or increased WT during the study. One subject developed acute symptoms of influenza and lost 3 kg; another subject did not advance the diet according to protocol and lost 1 kg. ED appeared to be well tolerated by study subjects, although adjustments in diet strength was needed occasionally. No clear trends were seen in pain, vomiting, bloating, nausea, and appetite.
Conclusion. Dietary management with a low-fat, low-residue, elemental diet may be a useful adjunctive therapy to help maintain body weight and reduce diarrhea in some HIV+ patients. Controlled studies should be conducted.

Th.B.P.301 IDENTIFICATION DES BESOINS D'INFORMATION EN NUTRITION AVEC L'INFECTION PAR LE VIH

Cossette, Michèle; CLSC CENTRE-VILLE, Montréal, Québec, Canada.

Objectif. Déterminer les besoins d'information en nutrition des personnes atteintes et des intervenant-e-s lors d'une infection par le VIH.
Méthodes. L'analyse des besoins s'applique aux adultes francophones de la région de Montréal affectés par le VIH. Une approche basée sur la recherche du consensus a été utilisée pour l'identification des besoins auprès des personnes atteintes et des intervenant-e-s. Dans l'ensemble, une centaine de personnes ont été consultées. Une combinaison de différentes techniques comme l'approche par informateurs-clés et la technique du groupe nominal a été utilisée pour faire ressortir les préoccupations en matière de nutrition et d'infection par le VIH.
Résultats. Les préoccupations majeures des personnes affectées par le VIH sont le maintien du poids, la stimulation du système immunitaire par l'alimentation, le potentiel de guérison des thérapies nutritionnelles alternatives ainsi que les solutions aux problèmes reliés à l'ingestion et à l'absorption de la nourriture tels que la diarrhée, la perte d'appétit, etc... Ces problèmes ainsi que le maintien du poids préoccupent aussi les intervenant-e-s. Ils-elles s'interrogent de plus sur les répercussions possibles de certaines pratiques nutritionnelles alternatives et de l'ingestion de suppléments alimentaires naturels ou de vitamines et minéraux sur l'état de santé de leurs clients.
Conclusion. En réponse aux divers besoins d'information exprimés, nous avons conçu 2 documents et 3 modèles alimentaires. La formation des intervenant-e-s en matière de nutrition figure également parmi les priorités d'action.

Th.B.P.302 AIDS NUTRITION NETWORK (ANN)

S.L. Matheny*, D.F. Moore*, WILLIAM F. HORN*/**. * Health Resources and Services Administration, Public Health Service, DHHS. ** Nutrition Services Consulting, San Jose, CA, U.S.A.

Purpose. To create a national/international information support system for dietitians/nutritionists responding to the nutritional needs of persons with HIV/AIDS.
Accomplishments. Increased professional membership (over 300 members) and awareness. Provided quarterly updates on nutrition issues to selected professionals based in community health centers, hospitals, state health departments and clinics, medical centers, universities and the private sector. Facilitated workshops/conferences and other training sessions via referral of human resources and print materials. Stimulated interest and cooperation of other professional groups, i.e., American Dietetic Association, Society for Nutrition Education, Association of State and Territorial Nutrition Directors, American Public Health Association and ASPEN Publishers.
Projections. 1. Develop regional resource referral stations.
2. Collect and catalog nutrition and AIDS curricula.
3. Stimulate the infusion of AIDS and nutrition curriculum into dietetic internship program course work and graduate nutrition courses in schools of public health.
4. Create a resource lending library.
5. Edit a nutrition and AIDS textbook.

Th.B.P.303 EVALUATION OF THE ZINC TASTE TEST (ZTT) IN AIDS PATIENTS

Johnson, Sandra† Peters, B.S†† Johnson, G††* Hems, G.M.† Pinching, A.J** Departments of *Dietetics, **Immunology and ***Chemical Pathology, St. Mary's Hospital, London, UNITED KINGDOM.

Objective. To compare the ZTT in AIDS patients with normal controls.
Methods. Malabsorption or dietary insufficiencies in AIDS patients may lead to nutritional defects. Some, such as zinc deficiency, may further compromise immune function. There is no accepted, reliable test for nutritional zinc status. Zinc is a component of gustin, a polypeptide involved in the sense of taste and patients with severe zinc deficiency have impaired taste. The ZTT (Bryce-Smith et al) has been suggested as a simple and sensitive means of detecting zinc deficiency. A colourless 0.1% solution of zinc sulphate is tasted, responses recorded on a taste scale of 1-4 (1=negative, 2=slight, 3=strong, 4=powerful/unpleasant). We conducted double blind tests using distilled water as comparison in 24 AIDS patients and 10 HIV negative controls. 4/24 AIDS patients had chronic diarrhoea and possible malabsorption. Serum zinc was measured in both groups; diet and nutritional status were assessed.
Results.

ZTT Result	AIDS Patients (24)	Controls (10)
Abnormal: 1,2	16	1
Normal: 3,4	8	9
Mean Serum Zinc umol/1	12.7	13.9
Standard Deviation of mean	2.7	1.86

Abnormal ZTT responses were seen in AIDS patients compared to HIV negative controls (Fisher exact test, $p<0.025$). Diet was comparable in both groups although nutritional status was much poorer in the AIDS patients.
Conclusion. If the ZTT can be confirmed as a marker of zinc deficiency it would provide a simple clinical means of assessing the need for zinc supplements in AIDS patients.

Th.B.P.304 GARLIC AS AN ANTIMICROBIAL AND IMMUNE MODULATOR IN AIDS

Abdullah, Tariq*; Kirkpatrick, D.V.**; Williams, L.* and Carter, J.**. *Akbar Research Foundation, Panama City, Florida, U.S.A., **Tulane University Medical Center, New Orleans, Louisiana, U.S.A.

Objective. To ascertain in a small preliminary trial the potential of garlic as an immune modulator and antimicrobial in AIDS.
Methods. Ten patients with documented HIV antigen and antibody positive infections began a 12 week experimental study taking 5 grams daily of an aged garlic extract called SGP (Special Garlic Preparation) for 6 weeks as a food supplement followed by 10 grams daily for another 6 weeks.
Results. Seven of 10 patients were able to complete the garlic regimen with significant improvement of immune parameters analyzed and of several opportunistic infections.

Immune Modulation Noted in AIDS with Garlic Extract

Patient ID	% NK Cell Activity - Helper:Suppressor Ratios* Baseline	6 Weeks	12 Weeks
1	4% - 0.5	53% - 0.4	28% - 0.2
2	5% - 0.8	26% - 0.8	38% - 0.8
3	12% - 0.2	33% - 0.3	68% - 0.3
4	2% - 0.7	14% - 1.0	28% - 1.9
5	3% - 0.2	38% - 0.3	30% - 1.0
6	10% - 0.2	28% - 0.4	35% - 0.5
7	2% - 0.5	-0-	25% - 1.1

*Normal range for NK activity is 22 - 85%. Normal range for Helper:Suppressor ratio is 0.8 - 1.8.

Conclusion. The above data suggest further studies are warranted to elucidate the therapeutic role of garlic in AIDS.

Th.B.P.305 PROTEIN TURNOVER AND SUBSTRATE CYCLING IN AIDS PATIENTS.

Stein, T. Peter , Coodoluci D , Nutinsky, C , and Bodwell, CE. . Univ. of Med. and Den. of NJ - SOM, NJ, and USDA, Beltsville, MD, USA.

Objective. Weight loss is a frequent finding in AIDS patients. The objectives were to determine whether this occured via a simple starvation type response or a 'hypermetabolic' response.
Methods. We compared (i) protein synthesis and breakdown, (ii) glucose cycling (G-CYL) through glucose 1,6 P and fructose-P and (iii) triacyl glycerol - free fatty acid cycling (TGFFA-CYL) in asymptomatic AIDS patients (I), septic AIDS patients (II) against healthy controls (III) and controls given a 40% calorie deficient diet for 4 weeks (IV). The PSR and PBR were measured with ^{15}N glycine, G-CYL with 6,6 D and 2-d glucose, TGFFA-CYL with 1-^{13}C palmitate and 5-d glycerol.
Results. Data is mean ± SEM, statistics by ANOVA or paired t-test. $p<0.05$ I vs II = a, I vs III = b, I vs IV = c and d = $p<0.05$ for III vs IV by one way paired t-test.

GROUP	I	II	III	IV	stats
n	9	3	6	6	
PSR (g prot/kg/d)	1.9(0.3)	2.9(0.3)	1.3(0.2)	0.9(0.1)	abcd
G-CYL (mg/kg/hr)	77(13)	194(109)	97(5)	89(4)	abd

Conclusion. (1) Asymptomatic AIDS have increased PSR as is found with other stress related protein wasting states (e.g. trauma, sepsis, CA). (2) Glucose substrate cycling is reduced more than is to be expected from reduced intake alone.

Th.B.P.306 EARLY PREDICTORS OF NUTRITIONAL STATUS IN HIV-INFECTION.

Beach, R.S.*,**, Mantero-Atienza, E.*,**,; Eisdorfer, C.**; Fletcher, M.A.**; Morgan, R.**; Fordyce-Baum, M.K.*,**;
*Department of Epidemiology **Biopsychosocial Center For Studies of AIDS. University of Miami, School of Medicine, Miami, Florida, USA.

Objectives. To determine nutritional parameters that may predict malnutrition early in the HIV continuum.
Methods. Subjects were 30 homosexual males seropositive for HIV who were asymptomatic except for lymphadenopathy (CDC Stage III). Anthropometric measurements (height, weight, left arm triceps skinfold thickness), serum albumin and total protein, retinol binding protein (RBP),and immunoglobulins were measured using standard techniques.
Results. Anthropometric determinations revealed 7% of the participants had significantly low body weight, triceps skinfold thickness and body mass index ($p<0.05$). In contrast, 25% of the subjects had RBP level below normal of 3.0-5.0 mg/dl, and additional 12% had RBP level in the marginal range of 3.0 - 3.5 mg/dl. Only 9% had serum albumin levels below the normal 3.5 - 5.5 mg/dl. Total serum protein was normal or high in all subjects, reflecting the increased levels of immunoglobulins.
Conclusion. RBP was shown in the past to be a more sensitive indicator of early malnutrition than more global measures, e.g. anthropometric measurements. The 25% of subjects with RBP below normal may indicate early signs of nutritional deficiency and may serve as an early prognostic indicator of those who will develop malnutrition.

Th.B.P.307 DIETARY INTAKE IN HIV INFECTION: RELATIVE CALORIC DEFICIENCY IN PATIENTS WITH AIDS.

Rowan T. Chlebowski, M. Grosvenor, S. Kruger, L. Bulcavage, K. Beck, G. Small. Harbor-UCLA Medical Center, Dept. of Medicine, Torrance, CA 90509, U.S.A.

The relentless weight loss in AIDS adversely influences patient survival (Proc ASCO 7:271), but has received only limited prior attention. To evaluate potential etiologic influences on nutritional status, dietary intakes of HIV infected pts with or without an AIDS diagnosis were determined using 7 day food records (to accurately estimate caloric and macro- and micronutrients). Caloric intake was correlated with clinical, nutritional, and immunological status. Most pts were receiving (50%) or had received (18%) therapy with AZT. Demographics were similar in the 14 HIV positive, non-AIDS pts [HIV] compared to 14 AIDS pts [AIDS], but nutritional and immunological status differed. Albumin, 4.1 gm/dl ±0.3 vs 3.5±0.4; no weight loss vs 8.7± 4.0% weight loss and CD4 of 436±67 vs 132±74 for HIV vs AIDS, respectively (all $p<0.05$). The significant weight loss experienced by AIDS pts was associated with a decreased current caloric intake compared to HIV pts without weight loss (2048±193 vs 2314±117 kcal/d, mean ±SEM). Protein and carbohydrate intakes were maintained in AIDS patients with caloric loss seen largely in fat. If maintained, the 266 kcal/d deficit seen in AIDS pts would result in an 8.7% decrease in weight in 4 months. We conclude that despite AZT therapy, a relative caloric deficiency in AIDS pts may represent a major contributing factor to the malnutrition.

Th.B.P.308 DIETARY INTERVENTION IN ARC PATIENTS.

Paul Kahl*, Sam Golden*, and Barry Sears**. *Medica, Homestead, PA 15220 and **BioSyn, Marblehead, MA , U.S.A.

Objective. To determine the role of dietary intervention in ARC patients.
Methods. A six month double blind placebo controlled study was conducted to determine the benefits of essential fatty acid supplementation on the clinicial status of 18 ARC patients. 10 patients were concurrently on AZT and were split between the active and placebo groups, thus intergroup comparisons could be made.
Results. Statistical analysis was conducted on the physician's assessment of the patient's clinical improvement using CDC criteria established for ARC patients. Ranking of the individual responses was based upon a subjective scale ranging from significantly improved (+2) to no change (0) to significantly worse (-2). Upon this basis using a t-test analysis the following conclusions were reached. The total active group (n=9) who had an average score of +1.00±0.24 did significantly better ($p\leq 0.005$) than the total placebo group (n=9) who had an average score of -0.56±0.34. Among the patients using AZT, similar results were obtained. Those using AZT and active (n=5) had an average score of +1.00±0.45 whereas those on the placebo and AZT (n=5) had an average score of -0.80±0.37. These results were also statistically significant ($p\leq0.01$). Patients using the active without AZT (n=4) had an average score of +1.00±0.00 which was statisically significant compared to patients on the placebo and AZT ($p\leq0.005$) and also to patients on placebo without AZT (n=4) who had an average score of -0.25±0.63 ($p\leq0.01$). There was no correlation between the clinical improvement and T_h or T_s counts which were taken every two months.
Conclusion. Dietary intervention with activated essential fatty acids improves the quality of life of an ARC patient. It remains unknown as to whether the course of the disease is altered.

Th.B.P.309 MEGESTROL ACETATE IN THE TREATMENT OF HIV-RELATED CACHEXIA.

J. Von Roenn, R. Murphy, L. Williams, S. Weitzman, Northwestern University, Chicago, IL, U.S.A.

Cachexia is a frequent problem in persons infected with the Human Immunodeficiency Virus (HIV). Megestrol acetate (MA) an agent used for the treatment of metastatic breast cancer has, as a side effect, appetite stimulation and weight gain. We have treated 22 HIV positive patients (14 previously reported) with MA beginning at a dose of 80 mg orally 4 times daily. All patients had lost at least 10% of their pre-illness weight. The median weight loss was 25 lbs with a range of 12 to 59 lbs. Patients (pts.) have been followed on therapy from 2 to 72 weeks. Twenty-one of the twenty-two pts. have gained weight. The average weight gain is 16 lbs (range - 9 to 38 lbs). Three pts. failed to gain weight on 320 mg per day of MA; 460 mg/day of MA in one and 640 mg/day in another pt., led to appetite stimulation and weight gain. One pt. continues to lose weight in spite of 480 mg/day of MA. The median time to peak weight on MA is 14 weeks. Seven pts. have returned to within a few pounds of their normal body weight. In 3 of the 22 pts. treated, MA and zidovudine were started simultaneously. For these 3 patietns weight gain was potentially due to the recognized weight gain associated with the initiation of zidovudine therapy. For the remaining 19 pts., appetite stimulation and weight gain were a result of megestrol acetate. All pts. have tolerated the drug well and report improvement in appetite while on therapy. No pt. has developed peripheral edema or drug related impotence. The appetite improvement and weight gain seen in this initial series is encouraging. The true effectiveness of MA for HIV related cachexia and its effects on quality of life is currently being passed in a national prospective randomized double blind placebo-controlled trial, the results of which may well be available by June.

Th.B.P.310 NUTRITIONAL ABNORMALITIES IN EARLY HIV-1 INFECTION. II. TRACE ELEMENTS

Fordyce-Baum, Marianna K.; Mantero Atienza, E.; Van Riel, P.; Morgan, R.; Beach, R.S.. The Biopsychosocial Center on AIDS University of Miami, School of Medicine, Miami, Florida, USA

Objective. To determine nutritional status in HIV-1 positive participants by measuring plasma trace elements by standard methodology.
Methods. We have examined fifty HIV-1 seropositive homosexual males who were asymptomatic other than lymphadenopathy (CDC stage III).
Results. Mean plasma zinc (Zn) was 0.81±0.07 (mean + SEM), considered within normal limits for adult males. While no subjects had Zn levels which were overtly deficient, 23% were marginal (0.70-0.85μg/ml), therefore at increased risk of developing Zn deficiency. In contrast, mean erythrocyte (RBC) Zn levels were sharply elevated with mean levels of 14.8 μg/ml ± 0.9, significantly higher than those of controls ($p<0.005$). Furthermore, 53% of study subjects had RBC Zn values above the range considered normal (>12.5μg/ml). Mean plasma copper (Cu) levels were significantly lower than those of controls ($p<0.001$) and 55% of subjects displayed deficient plasma Cu status (Cu<0.085μg/ml). Marginal Cu deficiency (0.85-1.00μg/ml) was found in 22% of subjects. Finally, mean selenium plasma levels were also significantly lower in participants than in controls ($p<0.005$). Forty two percent of subjects were below normal levels (<0.90μg/ml) and 27% were marginally deficient (90-120 μg/ml).
Conclusion. Trace mineral abnormalities early in the HIV infection may have important prognostic implications for disease progression, immune dysregulation and may provide an important adjunct for treatment of HIV-1 infected individuals.

Th.B.P.311 PLASMA NUTRITIONAL CHANGES ANTEDATE AIDS IN HEMOPHILIACS.

Andes, W. Abe*; Warrier, R.**; Lybanon J.I.*; Sharma R.***
*Tulane University School of Medicine, Section of Hematology/Oncology; **Louisiana State University, Department of Pediatrics; and ***Veterans Administration Hospital, New Orleans, Louisiana, USA.

Fourteen patients with hemophilia developed AIDS during a 29-month period. Seroconversion occurred after the use of nontreated coagulation factor concentrates from 23-75 (mean 53±16 S.D.) months before the diagnosis of AIDS. Their ages ranged from 7 to 74 and plasma and blood counts were taken at various times throughout their clinical courses. Five patients are still alive but 8 have died of complications of AIDS. Most patients developed clinical evidence of protein energy malnutrition before AIDS. In comparing values while patients were still seronegative with those values antedating AIDS by cholesterol fell 11, 28, and 13% respectively while retinol-binding protein (Rbp) actually rose 7%. T-helper lymphocytes (CD4) numbers were generally not tested before HIV exposure but fell after seropositivity. Their numbers did not allow prediction of the onset of AIDS.
Such measures of nutritional status may allow a better understanding of the evolution of AIDS in hemophiliacs and thereby prognostication. Mechanisms of the onset of disease may also be better understood which then offers the hope of better nutritional support and therapy of HIV infections.

Th.B.P.312 EFFECT OF ENTERAL NUTRITIONAL THERAPY ON BODY CELL MASS IN AIDS.

Ferraro, Robert; Kotler, DP; Culf, P; Tierney, AR; Smith, R; Heymsfield, S.
St. Luke's-Roosevelt Hospital, Columbia University, New York, NY, USA.

Objectives. To determine if enteral nutritional therapy can successfully *replete body cell mass in* malnourished AIDS patients; to determine if body mass repletion is associated with improvement in tests of immune function.
Methods. Six AIDS patients who had lost more than 10% of weight, ate less than 80% of estimated needs, had adequate xylose absorption, and no severe active complications were chosen for study. Nutritional therapy was provided using an percutaneous endoscopic gastrostomy tube (PEG), and consisted of a hydrolyzed protein solution (Reabilan HN, O'Brien Pharm). Nutritional assessments were performed 3 times over 2 months and included determinations of total body potassium (TBK), a measure of body cell mass, in a whole body counter, total body and extracellular water volumes by isotope dilution, and body fat content by anthropometry. In addition, selected immune studies were performed before and after nutritional therapy.
Results. The values for TBK increased significantly in all patients. There was a more variable effect upon body weight and body fat content. No significant changes were seen in total or CD4+ lymphocyte counts or serum immunoglobulin concentrations.
Conclusions. Enteral nutritional therapy can promote body mass repletion in AIDS. Successful nutritional therapy is not associated with obvious benefit in immune function.

Th.B.P.314 NUTRITIONAL KNOWLEDGE, HEALTH BELIEFS AND PRACTICES IN THE HIV-1 INFECTED PATIENT.

Mantero-Atienza, E.; Fordyce-Baum, M.K.; Van Riel, F.; Beach, R.S.
Center for the Biopsychosocial Study of AIDS, University of Miami School of Medicine, Miami, Florida, USA.

Objective. To assess nutritional beliefs and knowledge in HIV-1 positive gay males.
Methods. Seventy-five HIV-infected homosexual males, asymptomatic other than generalised lymphadenopathy, were interviewed to determine the nutritional health beliefs and knowledge using a standard questionnaire.
Results. 90% of the participants changed their diet at the time of, or subsequent to diagnosis of HIV-infection. The most common alternatives were decreased intake of red meat (37%), whole milk (31%), butter (21%) and alcohol (33%). Increased intake of vegetables (33%), fruits (32%), seafood (20%) and whole wheat bread/whole grains (21%); 87% of the participants felt that vitamin and mineral supplements could favorably influence their immune function with 59% reporting an increase in their consumption of such supplements since diagnosis; 90% did not know the daily requirements of essential vitamins and 50% consuming supplements did not know the amount they were consuming. The most frequently reported sources ofnutritional infor-mation and counseling were friends (75%),. newspapers and magazines (48%). Asymptomatic HIV-infected patients view nutritional and dietary issues of key importance in maintaining their immune function and asymptomatic status.
Conclusion. Subjects adapt strategies based upon a poor information base and these strategies may, at times, be ill-advised. Practitioners must provide the HIV-infected patient with basic nutritional information.

Th.B.P.316 FUNCTIONAL CORRELATES OF DECREASED SERUM ZINC IN HUMAN IMMUNODEFICIENCY VIRUS (HIV) DISEASE

Falutz, Julian; Tsoukas, C; Deutsch, G.
Montreal General Hospital, McGill University, Montreal, Canada

Objective:To determine the functional significance of the decreased serum zinc (Zn) that we have previously shown occurs in HIV disease, we studied the mitogenic effect of Zn on lymphocytes from patients and controls.
Methods:14 HIV+ men and 16 HIV- controls were studied. Proliferative responses of mononuclear cells (PBMC) to exogenous Zn, in concentrations from 0.01 mM to 2.00 mM, either in the absence or presence of PHA, were determined. The percent increase in the stimulation index (SI) at each Zn concentration relative to a saline control was determined. Statistical analysis of the mitogenic effect of each Zn dose was determined using t-tests for paired comparisons.
Results:Mean serum Zn of the HIV- & HIV+ groups were 17.0±2.5 & 14.1±2.8 mmol/L respectively (p<.05). Zn had a significant mitogenic effect on PBMC from controls only at the highest doses [Zn 1.00 & 2.00 mM:SI increase of 193±170% (p<.01) and 125±143% (p<.01)], whereas on HIV+ PBMC's, a greater range of added Zn produced a significant response [Zn .20,.50,1.00, & 2.00 mM:SI increase of 42+71% (p<.05), 52±78% (p<.05), 66±67% (p<.01), and 58±100% (p<.05) respectively]. In controls, no concentration of Zn augmented the SI achieved with PHA alone, whereas in HIV+ subjects, Zn at both 0.50 & 1.00 mM increased the SI due to PHA[22±27% (p<.01), and 34±43% (p<.01) respectively].
Conclusions:PBMC's from HIV+ subjects, with lower serum Zn, may be more sensitive to the mitogenic effects of Zn. Zn in HIV+ subjects only, may augment PHA induced proliferative responses. The decreased serum Zn found in advanced HIV disease may be a cofactor in HIV-induced immunosuppression.

Th.B.P.313 LOW VITAMIN B_6 LEVELS AND IMMUNE DYSREGULATION IN HIV-1 INFECTION.

Mantero-Atienza, E.*,**; Beach, R.S.*,**; Van Riel, F.*; Fletcher, M.A.**; Morgan, R.**; Eisdorfer, C.**; Fordyce-Baum, M.K.*,**;
*Department of Epidemiology **Biopsychosocial Center For Studies of AIDS. University of Miami, School of Medicine, Miami, Florida, USA.

Objective: To determine vitamin B_6 status and its relationship with immune indices in HIV-1 infection.
Methods: Subjects were 50 homosexual males aged 20-50 years who tested HIV-1 seropositive by Western blot and who remained asymptomatic other than lymphadenopathy. Pyridoxine status was evaluated by assessing stimulation of red cell aspartate aminotransferase. CD4 cell number and phytohemagglutinin (PHA) stimulation was performed by standard techniques.
Results: Thirty-five percent of study participants showed overt pyridoxine deficiency and an additional 18% marginal deficiency in spite of adequate B_6 dietary intake. A variable degree of depression of immune function was also noted; when correlated with pyridoxine status, individuals with vitamin B_6 deficiency had uniformly lower CD4 cell counts than did participants with normal vitamin B_6 levels. Moreover, the response of peripheral blood lymphocytes to mitogens such as PHA demonstrated significant correlation over the entire continuum of vitamin B_6 levels; subjects with the most deficient vitamin B_6 status had the poorest response to PHA (r=-0.42, P<0.004).
Conclusion: Pyridoxine deficiency occurs relatively frequently in HIV-infected individuals and may play a significant role in immune dysfunction and disease progression in the HIV-1 continuum.

Th.B.P.315 THE ROLE OF ZINC IN HIV-INDUCED IMMUNOSUPPRESSION.

Falutz, Julian; Tsoukas, C; Deutsch, G.
Montreal General Hospital,McGill University,Montreal,Canada

Objective:HIV infection causes a progressive but variable rate of CD4+ cell depletion. Cofactors may thus be important in disease progression. Zinc (Zn) deficiency causes reversible cell-mediated immune (CMI) abnormalities similar to those observed in HIV disease. We determined serum Zn levels and studied its functional role in HIV-infected subjects.
Methods:Serum Zn was measured in 200 subjects and controls (CDC HIV classification) by atomic absorption spectrophotometry. T cell subsets and serum albumin were measured. Proliferative responses of isolated mononuclear cells (PBMC) to phytohemagglutinin (PHA) were determined in 36 HIV positive subjects. Statistical analysis was based on Student's t-test between groups and regression analysis between variables.
Results:Groups IV-A, IV-D, and IV-C1 had serum Zn levels significantly less than in HIV negative controls (x̄=15.1±2.8, 14.4±2.0, and 12.9±2.4 mmol/L vs 17.1±2.8 mmol/L; p<0.05,p<0.01, and p<0.001 respectively). A significant correlation was found between the serum Zn (range 9.2-19.3 mmol/L) and the proliferative response of PBMC to PHA (p<0.01) but not between the number of CD4 cells (range 16-765/microL) and the proliferative response to PHA. There was no correlation between serum albumin (range 32-52 g/L) and PHA response.
Conclusion:Serum Zn decreases significantly in advanced HIV disease, and is correlated with the proliferative response to PHA. The absent correlation between albumin and PHA response suggests that the decreased serum Zn is of multifactorial origin. The lack of correlation between PHA response and CD4 concentration requires further investigation. Zn may be an important cofactor in the progressive immunosuppression occurring in HIV infection.

Th.B.P.317 EXOCRINE PANCREATIC FUNCTION IN HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN LONDON AND KAMPALA PATIENTS

Kapembwa, Moses; Fleming, S.C.; Sewankambo, N.°; Griffin, G.E.; Caun, K.§; Pinching, A.J.§ and Harris, J.R.W.§.
St. George's and §St. Mary's Hospitals, London, UK, °Mulago Hospital, Kampala, Uganda.

Objective. To assess exocrine pancreatic function (EPF) in HIV infection.
Background. Chronic diarrhoea and weight loss are common features of HIV infection and have been associated with jejunal villous atrophy in the absence of enteropathogens or intestinal Kaposi sarcoma. Such symptoms may however be seen in exocrine pancreatic insufficiency (EPI). This study tested the hypothesis that EPI is present in HIV infection.
Methods. EPF was measured using the PABA test in 25 London homosexual and 26 Kampala heterosexual HIV antibody positive subjects presenting at different clinical stages of infection (CDC groups II, III and IV). Control values were obtained in 25 London and 9 Kampala healthy volunteers. The recovery of Para-Amino Benzoic Acid (PABA) in urine (expressed as % oral dose) following oral administration of N-Benzoyl-Tyrosyl-para-Aminobenzoic Acid correlates well with direct measurements of luminal chymotryptic activity and is a validated index of EPI. Para-Amino Salicylic Acid (PAS) administered concurrently serves as a marker of PABA absorption and metabolism. Reduced PABA with normal PAS recovery results in low PABA excretion index (PEI) and is characteristic of EPI.
Results.

		%PABA#(normal>40%)	%PAS#(normal>40%)	PEI#(normal>0.70)
London	controls(25)	58.9±2.2	56.4± 1.7	1.05±0.04
	EPI(3/25)	**34.3±1.0	63.6±10.1	*0.57±0.08
Kampala	controls(9)	57.1±4.2	57.9± 5.1	1.04±0.09
	EPI(4/26)	Δ28.0±6.5	54.6± 5.4	Δ0.50±0.10

*p<0.01; **p<0.0001; Δp<0.05 compared to controls. #mean±SEM.

Conclusion. EPI was present in 3 (12%) London and 4 (15%) Kampala subjects and is therefore not a common feature of HIV infection.

SIDA buccal
Oral AIDS

Th.B.P.318 NUTRITIONAL STATUS PARAMETERS ASSOCIATED WITH PSYCHOSOCIAL WELL BEING SEEN IN AIDS/ARC CLIENTS AT AN OUTPATIENT CLINIC IN SAN FRANCISCO.

Bonnie Broderick, J. Messet, M.P.H., R.D., Mt. Zion Hospital & Medical Center/Better Health Programs, San Francisco, CA, U.S.A.

The purpose of this study was to (1) document changes in nutritional status from baseline measurements, (2) determine the efficacy of nutritional counseling, (3) define appropriate nutrition interventions, and (4) determine if nutritional status parameters correlated with psychsocial indices.

Patients underwent comprehensive nutritional assessment at both the initial outpatient clinic visit and after three months of routine nutritional counseling. Assessments consisted of anthropometric and biochemical measurements, three-day food records, nutritional histories, Hopkins Symptoms checklist, and Personal Orientation Inventory (POI), self-esteem and hassles questionaires. Education was provided on general nutrition and strategies for management of symptoms associated with opportunistic infections and other HIV disease-related conditions that may impact nutritional status. Additionally, a positive correlation between nutritional status and quality of life parameters were found.

Th.B.P.319 SINGLE-DOSE THERAPY FOR ESOPHAGEAL CANDIDIASIS WITH FLUCONAZOLE : A PILOT STUDY.

Chave, Jean-Philippe *; Vernazza, P.**; Margalith,D.*** and Glauser, M.P.*.
* Division of Infectious Diseases, *** Division of Gastroenterology, Centre Hospitalier Universitaire Vaudois, Lausanne, and ** Medical Clinic A, Kantonsspital, St.Gallen, Switzerland.

Objective. Oesophageal candidiasis is a frequent complication of symptomatic HIV infection. In this setting, topicals are ineffective, clinical resistance to ketoconazole is common, and amphotericin is poorly tolerated. Moreover, zidovudine has to be stopped (or can not be initiated) because of side-effects potentiation. In this context, the pharmacokinetic properties of fluconazole (a novel bis-triazole antifungal agent), such as a good oral absorption and a long plasma half-life, are of special interest.
Methods. Eleven adults with a biopsy-documented candidal esophagitis have received a single oral 400 mg fluconazole dose as sole treatment and have been seen again on days 3 and 7. The therapeutic response was ascertained in all cases by a second esophagoscopy on day 7, with cultures and biopsy of any lesion.
Results. On day 3, dysphagia was still present in 1/11 patient, who received a second 400 mg dose. Symptoms had disappeared in all patients on day 7, and endoscopic examination was normal in 10/11 cases. One patient presented persisting endoscopic inflammatory signs, but with no evidence of fungi on biopsy and culture. One other patient relapsed 41 days later (follow-up: 9-259 days, median 119 days). Transitory headache and nausea have been observed in one patient 6 hours after fluconazole ingestion. No other subjective side effect and no hepatic, renal or hematologic signs have been recorded.
Conclusion. These preliminary results suggest that a single oral dose of fluconazole may cure esophageal candidiasis and is well tolerated. This treatment ensures optimal drug compliance and could avoid hospitalisation and/or zidovudine interruption in patients with AIDS.

Th.B.P.320 SITES AND RELATIVE PREVALENCE OF HAIRY LEUKOPLAKIA, PSEUDOMEMBRANOUS CANDIDIASIS, AND ERYTHEMATOUS CANDIDIASIS.

Greenspan, Deborah*; Overby, G.*; Feigal, D.W.**; MacPhail, L.*; Miyasaki, S.*; Greenspan, J.S.*
The Schools of * Dentistry and ** Medicine, University of California, San Francisco, Oral AIDS Center, San Francisco, CA, U.S.A.

Objective: To describe the locations in the mouth where hairy leukoplakia (HL), and the various forms of candidiasis with their relative prevalence in a referral population to an Oral AIDS Clinic.
Methods: The Oral AIDS Epidemiology project initiated a uniform prospective set of data collection procedures for the oral complications of HIV in both community cohorts, AIDS clinics and the Oral AIDS Clinic. This analysis is based on the findings in the referral patients to the Oral AIDS Clinic. HL is biopsy proven in the majority of cases. Candidiasis is confirmed by KOH exam or cultures. The location of each lesion is sketched on a m.p of the mouth.
Results: Hairy leukoplakia was the most common lesion observed in 226 individuals. 87% of patients had involvement of the lateral (including extension to the ventral surfaces), and 29% the dorsum of the tongue. The buccal mucosa was less frequently involved , 3%, as was the soft palate (.4 %). (No lesions were seen on the hard palate). Pseudomembranous candidiasis (thrush) was observed throughout the mouth in 106 patients, most commonly involving the tongue, 42% lateral 48% dorsum. The hard palate 20% and soft palate (19%) were also frequently observed, as was the buccal mucosa (15%). Erythematous candidiasis (n=66), easily overlooked with a flat red appearance, was most frequently seen on the hard palate (60%), soft palate (17%), and dorsum of the tongue (57%) where depappilation was a common finding. Angular cheilitis due to candida was observed in another 14 patients.
Conclusions: Hairy leukoplakia although almost universally found on the lateral surface of the tongue also appears in the buccal mucosa. Pseudomembranous candidiasis occurs almost twice as often as the other manifestations of candidiasis and can affect almost any surface in the mouth. Erythematous candida is much more characteristic of the tongue and hard palate. Concurrent HL and candida was a common finding.

Th.B.P.321 ORAL FINDINGS IN PATIENTS WITH ASYMPTOMATIC HIV DISEASE

Schulten, Engelbert A.J.M.*; ten Kate, R.W.**, and van der Waal, I.*.
*Dept. Oral Pathology and Oral Surgery, **Dept. Internal Medicine, Free University Hospital, Amsterdam, The Netherlands.

Objective. To determine the prevalence of oral mucosal lesions in patients with asymptomatic HIV disease (CDC-II/III), and to compare the results with findings in patients with symptomatic HIV disease (CDC-IV).

Methods. Oral examination was performed in 70 HIV-positive patients (65 men, 5 women; mean age 36 yr; range: 18-65). Fifty-six patients (80%) were homo/bisexual men. Physical examination, including laboratory evaluation, was completed in all patients. Twenty-two, 11, and 37 patients were classified in group CDC-II, III, and IV, respectively. Of the latter group, 34 patients were diagnosed as having AIDS (CDC, 1987).

Results. In 52 patients (74%) one or more oral mucosal lesions were detected (CDC-II/III: 23 (70%); CDC-IV: 29 (78%)). Oral candidiasis, hairy leukoplakia, and periodontal disease were present in all groups.

Conclusion. Our data show, that oral mucosal lesions frequently occur both in asymptomatic and symptomatic HIV disease.

Th.B.P.322 SINGLE DOSE THERAPY FOR ORAL CANDIDIASIS WITH FLUCONAZOLE IN HIV-INFECTED ADULTS.

The Swiss Group for Clinical Studies on AIDS (Cajot, Angela; Division of Infectious Diseases, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland).

Objective. To assess the efficacy and tolerance of a single dose of fluconazole for the treatment of oral candidiasis (OC). Fluconazole (FCA) is a new antifungal agent with a good oral absorption and a prolonged half-life.
Methods. From 1.10.1987 to 1.11.1988, all patients presenting with OC were proposed a single 150 mg dose of FCA. Diagnostic criteria for OC included mouth symptoms (burning, pain, dryness) and signs (white patches on a hyperemic base) with a positive swab culture. Patients were asked to attend weekly visits for two months. Clinical response was defined by the total disappearance of signs and symptoms. Relapses were treated with another single dose.
Results. Forty-five patients were included: 26 of them had presented ≥ 1 prior episode of OC within the last 12 months, and AIDS was present in 28. A response was noted in 39/45 patients (87%) on day 7 and in 16/43 (37%) on day 21 after the first 150 mg dose. The median follow-up observation period was 55 days (95% CI: 17 to 84), with a cumulative total of 2308 patient-days. During this follow-up period, 27 patients (including 22 with AIDS) presented 59 relapses, all of which responded to a single dose FCA. Median interval before relapses was 14 days (95% CI: 6-45). Analysis of variance showed that patients with AIDS and previous OC history were more likely to relapse. Altogether, of the 111 clinical OC episodes during this study, 93 (84%) responded to a single 150 mg dose. Two patients had minor side effects (nausea).
Conclusion. FCA single dose therapy for OC was easy to administer, effective and well tolerated in this pilot study. Relapses were more frequent in patients with a history of OC and with a symptomatic HIV infection. These episodes responded again to another FCA single dose, suggesting the absence of clinical resistance. The single dose approach could avoid continuous treatment in patients already receiving multiple therapies.

Th.B.P.323 THE IDENTIFICATION AND TRACKING OF CANDIDA ALBICANS ISOLATES FROM ORAL LESIONS IN HIV-SEROPOSITIVE INDIVIDUALS

Miyasaki, Shelley H.*; Polacheck, I.**; Hicks, J.**; Greenspan, D.* and Greenspan, J.S.
*Oral AIDS Center, U.C.S.F., Calif., **Research Inst. of Scripps Clinic, La Jolla, Calif. USA

Objective. Candida albicans is recognized as the most frequent cause of oral candidiasis in HIV infection, however, very little else is known regarding these C. albicans biotypes.
Methods. Clinical isolates were obtained from 26 HIV-seropositive individuals with and without oral lesions, plus 8 HIV-seronegative controls. The isolates were hybridized with a number of C. albicans specific DNA probes to assess strain relatedness between isolates obtained over time. The DNA probes yield a "fingerprint" that can be used to follow individual C. albicans strains for long periods and through repeated re-isolations.
Results. C. albicans has been isolated from all individuals with oral lesions. We have determined that each individual in the study carries a distinct C. albicans strain identifiable by its DNA fingerprint. Furthermore, C. albicans was isolated from a significant fraction of asymptomatic individuals both HIV-seropositive and HIV-seronegative. In the two cases so far observed where new lesions developed following "successful" antifungal treatment, the same strain was found, indicating that the same yeast is harbored by the individual during the asymptomatic phase.
Conclusions. The finding of the same strain of C. albicans both before and after standard antifungal therapy raises questions as to the effectiveness and aims of current accepted therapeutic regimens. If in fact C. albicans organisms are altered under selection pressure from the host environment or can adapt to each host uniquely, than it is not surprising that they are such successful opportunistic pathogens. The present finding of a unique C. albicans strain in each individual harboring C. albicans suggests a mechanism for this yeast's continued presence in a population of immunocompromised and nonimmunocompromised individuals.

Th.B.P.324

ORAL MUCOSAL LESIONS AND LYMPHADENOPATHY IN HIVI SEROPOSITIVE PATIENTS.

Manzala P.[1], Manji F.[1], Plummer F.[2], Pindborg J.J.[3]

1. Kenya Medical Research Institute
2. University of Nairobi, Microbiology Department & University of Manitoba, Winnipeg, Canada
3. Royal Dental College, Copenhagen

Findings of an examination of oral mucosal lesions related to HIVI, and palpation for enlarged lymphnodes done on a cohort of 334 women prostitutes by September 1988 are presented.

In the seropositive patients (80% of the women), oral mucosal lesions were found in 13.2% (mainly oral candidiasis) whereas persistent generalized lymphaderopathy (PGL) was found in 42.2% individuals.

	WITH LESIONS		WITH NO LESIONS	
	No.	%	No.	%
PGL	24	55.1	94	32.2
No PGL	20	44.9	196	67.8

(Chisquare = 8.16 p-value = 0.004)

The epitrochlear lymphnodes were most affected in both groups, and in addition with the supraclavicular and the submandibular, statistical significant difference in occurence was found between the two groups.

The data suggests that these two clinical parameters may be useful indicators of early progression of HIVI infection in these women.

Th.B.P.325

ORAL MUCOSAL LESIONS IN INFANTS OF HIV+ve AND HIV -ve MOTHERS.

Manzala P.*,Datta P.**,Temmerman M?* , Pindborg J. J.***, KisumbiM,**** , Kariuki H.**** , * Kenya Medical Research Institute, ** University of Nairobi (Microbiology Dept.),*** Royal Dental College, Copenhagen, **** University of Nairobi(Dental School)} Kenyatta National Hospital (Dental Clinic). Nairobi.

OBJECTIVE :- The aim of the study was to determine the prevalance of oral mucosal lesions in infants of seropositive and seronegative mothers.
METHOD :- Infants of HIV +ve and HIV -ve mothers enrolled in a vertical HIV transmission study in Nairobi, Kenya were followed. prospectively and were examined for occurrence of oral mucosal lesions. Smears were obtained for microscopic examination.
RESULTS :-

	Maternal HIV status		
	Seroneg.(n = 106).	Seropos (n=58).	
A.Mean age of infants at examination.(weeks).	19.5	31.9	
B.Lesions in infants.	n(%)	n(%)	p-value
1.Pseudomembranous cand.	7(6.6)	4(6.9)	.92
2.Erythematous candid.	7(6.6)	5(8.6)	.72
3.Hyperplastic Candid.	1(0.9)	1(1.7)	.71

(Mantel-Haenszel test,odds ratio = 1.22, with age statified).
CONCLUSION :- The results indicate that the occurrence of oral lesions (mainly oral candidiasis)is not HIV-specific forinfants.

Th.B.P.326

ERYTHEMATOUS CANDIDIASIS: EARLY CLINICAL MANIFESTATION IN HIV-REACTIVE PATIENTS

Cahn,Pedro*;Casariego,Z*;Pérez,H*;Casiró,A*;Grinberg,N*; Muchinik,G**,et al.
*Hospital Fernández,**IIHEMA,Academia Nacional de Medicina,Buenos Aires, Argentina.

Objective. To evaluate Erythematous Candidiasis (EC)in asymptomatic HIV-reactive patients (aHIV Pt).
Methods. Clinical follow-up and stomatological control of 105 aHIV Pt was made during 8 months. Dental-eye photograph was taken and culture performed for those lesions suspected of EC. Nystatin and/or gentian violet were administered locally to confirmed cases, while severe ones were treated orally with Ketoconazol.
Results. EC shows as a diamond-like reddish spot(72%) or as "patches"(28%) in the median and back raphe before the *papillae vellate*, causing disappearance of filiform papillae(58% of the cases), in the hard palate(49%), in the soft palate(42%) and in the jugal mucosa(12%). More than 1 site was found in 65 Pt. Only 3 Pt showed evolution towards pseudomembranous candidiasis 8 months later.
Conclusion. EC was the only clinical manifestation found in the 105 aHIV Pt studied. Early diagnosis may be useful as an early clinical marker; likewise, early treatment may delay evolution towards pseudomembranous candidiasis, which involves greater severity.

Th.B.P.327

HAIRY LEUKOPLAKIA IN SPANISH HIV-INFECTED PATIENTS:AN EARLY MARKER OF HIV-DISEASE PROGRESSION.

Podzamczer,Daniel; Bolao,F.; Pagerols, X.; Romeu,A.; Gudiol, F. Hospital de Bellvitge. University of Barcelona. Barcelona. Spain.

Objective. To study the incidence of hairy leukoplakia (HL) and its value as a clinical sign of progression of HIV-infection.
Patients and methods. Three hundred seventy two HIV-infected pts were observed during a 4-year-period: 299 drug addicts (DA), 38 homosexuals (HMS), 8 both groups (DH), 21 heterosexuals (HTS) and 6 other risk groups. The diagnosis of HL was made using clinical and/or histological criteria.
Results. Fifty five (15%) pts presented HL: 39/239 DA (13%), 11/38 HMS (29%) 2/8 DH (25%) and 3/21 HTS (14%). HL was diagnosed in 27% of 78 AIDS pts (HL-AIDS), and in 12% of 306 pts in earlier stages of HIV-infection (HL-preAIDS) Other mucocutaneous lesions (MCL) were observed in 90% of HL-AIDS pts and in 37% of HL-preAIDS pts ($p < 0.0001$). In HL-preAIDS pts, HL was the first clinical sign of HIV-disease progression to CDC-IV group in 59%, while in the remainder 41% it was associated to constitutional symptoms or other infections of CDC-IV-C2 group. Serum CD4+ values of pts with HL was 0.25 x 10/L, range 0.02-0.59. HL was observed earlier than oral candidiasis (64% in preAIDS and 36% in AIDS vs. 29% in preAIDS and 71% in AIDS respectively)$p < 0.001$
Conclusions. 1) HL is a frequent event in spanish HIV-infected pts and may appear in different risk groups. 2) In our population HL presents earlier than other CDC-IV-C2 group infections such as oral thrush. 3) In more than half of our preAIDS cases HL was the only MCL observed and the first clinical sign of HIV-disease progression. 4) HL may be an early indication for antiretroviral therapy.

Th.B.P.328

ITRACONAZOLE VS KETOCONAZOLE IN THE TREATMENT OF MUCOCUTANEOUS CANDIDOSIS.

DON.E.SMITH. M.ALLAN. G.M.CONNELLY. J.MIGLEY. B.G.GAZZARD. ST.STEPHENS HOSPITAL, FULHAM ROAD, LONDON, UNITED KINGDOM.

OBJECTIVE: To determine the efficacy of Itraconazole or Ketoconazole in the treatment of buccal or buccal and oesophageal candidosis in ARC and AIDS patients.
METHOD: 100 HIV positive patients with mucocutaneous candidosis were randomised to a 4 week course of either Itraconazole or Ketoconazole in a double blinded study. Clinical and mycological assessments were made at entry,one week and four weeks. All patients with dysphagia were endoscoped at entry and again at end of treatment. Patients were followed up for three months after completeing the treatment course to determine time to relapse.

RESULTS:	RESPONSE (buccal) CLINICAL/	MYCOLOGICAL	RESPONSE (oesophageal) CLINICAL	RELAPSE WITHIN THREE MONTHS
ITRACONAZOLE:	39 (98%)	30 (77%)	11 (92%)	27 (82%)
KETOCONAZOLE:	38 (100%)	34 (92%)	10 (100%)	28 (80%)

Adverse reactions; There were statistically more episodes of hepatotoxicity with Ketoconazole 2/48 (4%) vs Itraconazole 0/52 (0 %).
CONCLUSION: Itraconazole appears equally as effective as Ketoconazole in acheiving clinical responses (98% vs 100%) but has a lesser effect on mycological responses (77% vs 92%). However Itraconazole has a much lower incidence of hepatotoxicity and therefore is justfiable as a first line therapy for mucocutaneous candidosis in ARC and AIDS patients.

Th.B.P.329

Oral candidiasis (o.C.) determined by a quantitative method - correlation to marker of the immunologic system

Plettenberg, Andreas*, E.Reisinger**, U.Lenzner*, H.Ernst***, P.Kern**, W.Weigel*
* Allgemeines Krankenhaus St. Georg, Hamburg - ** Bernhard-Nocht-Institut, Hamburg- *** Forschungsinstitut Borstel, Borstel, Germany

Objectives:1) To study the advantage of quantitative determination of yeasts in throat washing 2) To determine the correlation between o. C., neopterin- level, CD4-cell counts, Zolla-Pasner- classification (Z.P.C.) and progression to Aids
Methods: 29 patients (pat) in WR- stage II- IV were investigated at the beginning of the study and after 6, 12, 18 and 24 weeks. The parameters included a clinical check up of the oral mucosa, yeast counts of throat washing (pathologic > 10^3), neopterin levels (normal: < 11 nmol/l) and counts of CD4- and CD8- lymphocytes.
Results: 11 of the 29 pat developed o.C. 6 pat had a progression to Aids, 5 out of these 6 pat developed o.C. prior to progression to Aids. The median time between first diagnosis of o.C. and Aids was 10 weeks. In pat with CD4- counts < 400 at the beginning of the study o.C. occured in 70 %. Pat with neopterin levels > 20 nmol/l showed o.C. in 63 %. Pat with Z.P.C. II or III at the start of the study, showed o.C. in 73 % (s. tab.). In the throat washing of one pat, who later developed a Candida-Oesophagitis, we found pathologic yeast counts several times, but we never observed clinical signs of o.C.

	Nr.of pat	at start of study			during the study
		CD4- cells	neopterin	Z.P.C.IIorIII	progression to Aids
o.C.	11	417	23.6	8 (73 %)	5 (45 %)
no o.C.	18	763	14.3	4 (40 %)	1 (6 %)

Conclusion: There is a statistically significant correlation between alteration of immunologic markers and the manifestation of Aids. The progression to Aids in 5 of 11 pat with o.C. after a median time of 10 weeks demonstrates the prognostic value of o.C. The determination of yeast counts in throat washing is a useful method to evaluate the manifestation of Candida in oral mucosa.

Th.B.P.330 ORAL MELANOTIC MACULES IN PATIENTS INFECTED WITH HIV-1

Picarra, Giuseppe*; Shillitoe, E.**; Adler-Storthz, K.**;
Gaglioti D.*; Di Pietro, M.*; Riccardi, R.*.
*University of Florence and USL 10/D, Florence, Italy;** University of Texas, Houston, Texas, Houston, USA.

Objective. To describe the features of 9 cases of oral melanotic macules (OMM) in patients (pts) infected with HIV-1.
Methods. Between Dec.87 and March 88, 9 pts developed OMM. Plasma cortisol level was measured. Electron microscopy was done in 5 specimens. In situ hybridization to Epstein-Barr virus (EBV) was done under stringent condition.
Results. The mean age was 31.6 years. Five pts were men and 4 women. Six pts were IVDA. One pt had asymptomatic infection, 3 LAS and 5 ARC. In 3 pts the OMM were single and in 6 multiple. None of the pts developed clinical or laboratory evidence of adrenal damage. Six pts received treatment courses of topical nystatine or systemic ketoconazole. Six pts also had hairy leukoplakia. Increased melanin deposition in the basal-cell layer and upper lamina propria was observed. In 6 cases koilocytes were present. No ultrastructural alterations were observed. DNA of EBV was found in 2 OMM tissues and in 1 specimen of normal mucosa. In some pts the OMM enlarged or recurred after excision.
Conclusion.The etiology of OMM is not know, although several causes should be considered. Subtle adrenal damage, latent viral infection and drug therapy can be involved. OMM might represent a new manifestation of HIV-1 infection.

Th.B.P.332 IMMUNOHISTOCHEMICAL STUDIES OF ORAL SCRATCHES IN HIV INFECTED PATIENTS.

Langford,Angelika[1], Kunze,R.[2], Schmelzer,S.[1], Pohle,H.D.[3], Reichart, P.[1].
Free University[1], Robert Koch Inst.[2], Rudolf Virchow Univ.[3], D-1-Berlin-65, FRG

Objective: To examine keratinocytes gained from oral scratches for viral antigens and cytokeratin differentiation markers.
Material and methods: Scratch material (lat. border of the tongue) (HIV+ patients n=30, HIV- n=20) was filtered, centrifugated onto slides and examined by means of immunohistochemistry (APAAP) and in situ hybridisation (ISH). Applied antibodies: anti cytokeratin (K) 8.60, K 8.12 and K 4.62 and Kl1; EBV, CMV, HSV 1/2.
Results: Compared to HIV- in scratches of HIV+ the number of K 8.60 ("cornification marker") positive cells was 2.6 times increased, of K 8.12 ("fast cell turnover") 2.5 times and of K 4.62 ("basal cell marker") 7 times. In scratches of HIV+ patients the number of Kl1 positive cells was 3 times higher than in HIV-. Viral antigens of EBV were not detected in HIV-, but in 15/30 HIV+ patients (APAAP, ISH); 10/15 showed oral hairy leukoplakia (HL), while 3 further patients developed HL during an observation time of 8 months. CMV was observed in 8/30 (ISH) and in 6/30 HIV+ patients (APAAP). In 9/30 (HIV+) patients HSV1/2 + cells were found (ISH). Detection of viral antigens and of immature keratinocytes was highly correlated with AIDS manifestations.
Conclusion: 1. The presented non-invasive technique ("scratch") is a sensitive aid for regular monitoring of HIV associated oral lesions, such as HL. 2. Proliferation and differentiation of cytokeratin in oral epithelium is altered during HIV infection.
3. Detection of EBV in oral scratches seems to be a valuable marker for the later development of HL.

Th.B.P.334 FLUCONAZOLE IN THE TREATMENT OF OROPHARYNGEAL CANDIDIASIS IN HIV-POSITIVE PATIENTS.

Just, Gudrun*, Schnellbach, M.*, Böttinger, C.*,
Gentschew, G.*, Helm, E.B.*, Stille, W.*
*Universitätsklinik Frankfurt, ZIM, Infektiologie, Theodor-Stern-Kai 7, 6000 Frankfurt, FRG

Objective: To describe efficacy and restrictions of Fluconazole in the treatment of oral candidiasis in AIDS-patients.
Methods: 104 HIV-positive patients with clinical and cultural signs of oropharyngeal candidiasis were treated in 112 treatment courses. Initial dosage was 200 mg/die, followed by a daily dosage of 100 mg. Duration of therapy was approximately 3 weeks in approximately 60% of cases. For quantification of colonisation, the oral wash-out method was used.
Results: At the end of treatment with Fluconazole, clinical symptoms and complaints completely disappeared in approximately 90% of patients, although the oral wash-out still showed a remarkable number of candida spp. in the culture. The group of "non-responders" consisted of patients in an advanced stage of disease, patients under cytostatic therapy, or of patients with a selection of C. glabrata (12 patients) or C. tropicalis (2 patients). Fluconazole was well tolerated with only a small number of adverse effects even after long term therapy.
Conclusion: Fluconazole is effective in the treatment of oropharyngeal candidiasis. Elimination of clinical symptoms and complaints is not always accompanied by elimination in the culture. The selection of C. glabrata might become a therapeutic problem.

Th.B.P.331 LOCAL DESTRUCTION OF LABIAL SURFACE OF MANDIBULAR TEETH BY DIRECT APPLICATION OF COCAINE IN DRUG USERS WITH AIDS

Quart, Arthur M.; Small, C.B. and Klein, R.S.
North Central Bronx Hospital, Albert Einstein College of Medicine, Bronx, New York, U.S.A.

Objective. To describe a newly recognized oral lesion in drug users with AIDS.
Methods. 92 consecutive drug users with AIDS underwent periodontal and oral examination by a periodontist. Destructive lesions not explicable on the basis of periodontal disease or other recognized oral pathology were noted and photographed. Patients were questioned about direct mucosal application of cocaine.
Results. Five patients had focal destruction of the soft and hard tissue of the labial surface of mandibular anterior teeth. Affected areas could not be attributed to adjacent periodontitis. Subjects included 3 male and 1 female intravenous drug users (IVDU) and 1 female who denied parenteral drug use and whose risk behavior for AIDS was sexual contact with an IVDU. All 5 reported at least several weeks of cocaine use by direct application to the affected areas, described as the "freeze" method of cocaine use.
Conclusion. Drug users with AIDS who take cocaine by the "freeze" method are at risk for focal destruction of oral tissue at the site of drug application. Individuals involved in the oral care of drug users with AIDS should recognize this entity.

Th.B.P.333 RECURRENT ORAL APHTHAE IN HIV-INFECTED HOMOSEXUAL MALES.

Lozada-Nur, Francina; Huang, M. and Silverman S., Jr.
University of California, San Francisco, San Francisco, CA, U.S.A.

Objective. To develop a profile and assess cofactors in HIV positive homosexual males afflicted with progressive oral aphthae.
Methods: 12 homosexual males; 9 with AIDS and 3 patients with ARC were evaluated and treated. Mean age was 37 (range 27 to 56). Followup mean 10 months. Patients were divided into 2 groups — those with lesions <6 mm (minor), >6 mm (major). History of recurrent aphthous ulcerations, frequency, and disease severity prior to 1988 and after HIV test, time of diagnosis of ARC or AIDS and medications were recorded. Tests included HSV by monoclonal Ab, culture (bacterial and fungal) and complete blood counts.
Results. 9/12 patients had a previous history of recurrent aphthous prior to HIV infection; 8 patients presented with major ulcers and 4 with minor ulcers; severity and frequency of their oral disease has worsened in 9 patients prior to the onset of ARC or AIDS and in 3 patients after the diagnosis of AIDS; 9/12 tested patients were negative to HSV; 6/8 patients with major ulcers were anemic and neutropenic: RBC (mean 2.6), Hb (mean 9.5), WBC (mean 2.5); all patients responded to therapy whether systemic (Prednisone) or topical (Clobetasol propionate).
Conclusion. Increased severity and frequency of RAU is a complication of HIV infection; anemia and neutropenia appear to be cofactors; RAU in HIV positive patients is not HSV related; patients with the major type are likely to be anemic and neutropenic.

Th.B.P.335 CARRIAGE OF ORAL CANDIDA ALBICANS : CORRELATIONS WITH HIV INFECTION AND CELLULAR IMMUNITY IN HEROIN ABUSERS.

Muga Roberto, Tor J.,Moltó E.,Ginestá C.Rey-Joly C,Foz M.
Service of Internal Medicine.Hospital de Badalona "Germans Trias i Pujol".
Universitat Autònoma de Barcelona.Barcelona.Spain.

Objective. To study the carriage of oral candida albicans in intravenous drugs abusers (IDAs) and their relationship with HIV infection and underlying immunodeficiency.
Methods. 196 IDAs (130 M ,39 F) were studied from 1/86 to 12/87. HIV test (ELISA),CD4-CD8 lymphocyte counts and CD4/CD8 ratio were practised.Oral samples were included in Stuart medium and cultivated in Sabouraud medium. Results were lectured the 7th day after Gram stain.
Results. 73% of IDAs were carriers of 1 or more candida albicans colonies vs 29.6% of controls (p<0.001).HIV prevalence was 77.9% (127/163) without difference in the number of colonies for seropositives (40.9±57.8 col) and seronegatives (32.6±56 col)(p=0.44).Oral thrush (35.6% of patients) was related to a greater number of colonies (64.8±59.4) comparing with cases without oral lesions (22.6±44.2 col;p=0.009). Association between oral thrush and HIV seropositivity (p<0.04) was also demonstrated.However, being asymptomatic carrier of 1 or more colonies could not be associated for HIV serostatus (p<0.44).
73 out of 96 (76%) patients with CD4/CD8 had a ratio lower than 1.2 with a mean of 39.3±53 col. and 23 cases with CD4/CD8 >1.2<2.1 showed 26.3±36.7 col. (p=0.718).
Conclusion. There is a high incidence of candida albicans carriers in IDAs, but this finding not appear related to HIV infection or underlying immunodeficiency in asymptomatic heroin abusers.

Th.B.P.336 TUMEURS LYMPHOIDES DU CAVUM AU COURS DE L'INFECTION PAR LE V.I.H.

Pulik, Marc * ; Oksenhendler, E. ** ; Lido, H. * ; Gaulier, A. * ; D'Agay, M.F. ** ; Clauvel, J.P. **.
* Hôpital Victor Dupouy, Argenteuil, France, ** Hôpital Saint-Louis, Paris, France.

Objectif. Décrire les 3 premiers cas de tumeur lymphoïde polyclonale du cavum chez des patients séropositifs, et préciser leur nature.
Méthodes. Examens endoscopique et tomodensitométrique. Histologie et immuno-marquage pour étudier la composition cellulaire. Etude du réarrangement des gènes du récepteur T et du gène des immunoglobulines pour affirmer le caractère mono ou polyclonal. Recherche du génome viral en hybridation moléculaire pour apprécier le rôle pathogénique éventuel de l'EBV.
Résultats. Une otalgie et un encombrement nasal chroniques font découvrir une volumineuse tumeur du cavum n'envahissant pas les structures osseuses, chez 3 hommes (28, 30, 33 ans) porteurs d'anticorps anti-VIH1 (2 toxicomanes, 2 originaires des Caraïbes). Dans 2 cas il existe un syndrôme sec, associé à une parotidite chez 1 patient, à un syndrôme lymphadénopathique et une hypertrophie amygdalienne chez l'autre. Dans les 3 cas on note : une lymphopénie T4 (588, 497, 280/mm^3) : une hypergammaglobulinémie polyclonale (21.3, 22, 29 g/l). La biopsie révèle une prolifération lymphoïde intense composée de lymphocytes polyclonaux B et T (à prédominance de T4 : 60 %). Il n'y a pas de réarrangement du gène des immunoglobulines ni du récepteur T (3 patients). La recherche d'EBV en hybridation moléculaire est négative dans les biopsies (2 patients).
Conclusion. Nos 3 observations élargissent le spectre des tumeurs lymphoïdes polyclonales observées au cours de l'infection VIH. Ces tumeurs du cavum symptomatiques ont une composition histologique identique à celle observée dans les ganglions du syndrôme lymphadénopathique. Le rôle de l'EBV souvent évoqué dans les proliférations lymphoïdes des immunodéprimés ne semble pas pouvoir être retenu ici.

Th.B.P.337 ORAL PATHOLOGY IN HIV INFECTED PACIENTS

Bertazzoli,RCB;Rissi,AC;Rissi,RCG;Lima,MPJS;Bellucci,SB.
Centro Corsini. Campinas. Brazil (CCII)

Objective:Diagnostic and early treatment of oral manifestations in HIV infected patients.
Method:HIV positive test pacients (E/WB) listed in the CCII were examined by the Center's Dental Dept. Pacients without symptoms are reexamined each two months, and patients presenting symptoms are examined whenever necessary.
Results:Of 66 pacients examined,34 did not show symptoms in the first exam, and throughout the program, only 6 developed some oral pathology. The first and most frequent pathology found was candidiasis. Gengivitis was also observed in 4 pacients. In patients presenting symptoms in the first consultation (32) the most frequent oral pathology was gengivitis following candidiasis SK was observed in 2 patients.
Conclusions:a)The majority of the pacients which did not present symptoms in the first exam follow the initial exam, remain without symptoms;b)The concern with oral health maintenance reflects in the search of a better quality of life the positive test pacients;c)The dental dept. has shown a very important part in keeping the patient within the CCII's program.

Th.B.P.338 CORRELATION OF HIV IN GINGIVAL CREVICULAR FLUID WITH HIV IN SERUM

Winkler, James R.*; Murray, P.A.* ; French, C.K.**; Lippke, J.A.**; and Vaccaro, K.K.**
Oral AIDS Center, University of California San Francisco, USA and BioTechnica Diagnostics, Cambridge Massachusetts, USA

Objective: To determine the presence of HIV in gingival crevicular fluid (GCF) and to correlate the presence of HIV in GCF to HIV in the serum.
Methods: Samples were taken from 3 tooth sites in 35 HIV-positive men and 47 HIV-negative men. GCF and associated subgingival plaque (2 µl) was collected by paper points placed to the base of the periodontal pocket. The fluid and associated cells were solubilized and prepared by standard procedures and hybridized with a commercially available HIV-DNA probe.
Results: In all cases, all three sites were either negative or positive. As seen in the table, the sensitivity of the DNA probe assay was 91.4% and the specificity was 91.5%.

	Western Blot		
DNA Probe	HIV+	HIV-	Total
HIV+	32	4	36
HIV-	3	43	46
Total	35	47	82

Conclusion: These results suggest detection of HIV in blood and in GCF is approximately equal, and that the DNA probe is specific for the detection of HIV. In addition, these data suggest GCF as a potential site of HIV in oral fluids. Furthermore, the ease of sample collection and sample stability, may make examination of GCF an additional tool for epidemiologic surveys in large patient populations or in third world nations.

Th.B.P.339 AN IMMUNOHISTOCHEMICAL AND ULTRASTRUCTURAL STUDY OF ORAL HAIRY LEUKOPLAKIA IN HIV-POSITIVE PATIENTS

Mongiardo,Nicola*;Manca V.**;Pellegrino F.*;Lami G.*; D'Andrea L.* and De Rienzo B.*.
*Dept.Infectious Diseases and **Dept.Dermatology,University of Modena,Italy.

Objective.The aim of our study was to describe the ultrastructural features of hairy leukoplakia (HL) and to confirm the presence of Epstein-Barr virus (EBV) by immunohistochemistry and transmission electron microscopy (TEM).
Methods.Biopsy specimens of HL were taken from the lateral border of the tongue of 3 HIV-seropositive male patients belonging to stage IV C2 of the CDC classification and processed for routine histopathology,immunohistochemistry and TEM.
Results.The common histological features were a mild hyperkeratosis,parakeratosis and acanthosis of the epithelium,with characteristic koilocytotic prickle cells.In the upper epithelial layers the presence of EBV antigens was detected using an anti-EBV policlonal Ab in a three step immunofluorescence technique on frozen sections.At the ultrastructural level,ballooned keratinocytes were observed within the spinous layer.The infected cells were increased in size,with few cytoplasmic organelles and degenerated mitochondria; their pycnotic nuclei showed areas of condensed chromatin.The nuclei contained varying amounts of viral nucleocapsids.Some showed the central electrondense portion typical of herpes viruses.In our investigation the papilloma virus was not detected at the EM level.

Th.B.P.340 ORAL KAPOSI'S SARCOMA: THE SEQUENCE OF APPEARANCE WITH RESPECT TO OTHER AIDS COMPLICATIONS

Dodd C.L.*, Greenspan, D.*, Overby, G.*, Feigal, D.W.*, Hollander H.*, Schiødt M.*+, MacPhail, L.* and Greenspan, J.S.*. *University of California, San Francisco, Oral AIDS Center and the Adult Immunodeficiency Clinic (AIC); +University Hospital and Royal Dental College, Copenhagen, Denmark.

Objective: To describe the natural history of mucosal Kaposi's sarcoma (KS) in the sequence of the development of other AIDS complications.
Methods: Since 1985 a prospective registry of all new patients to the AIDS clinics at UCSF, including 774 men and 16 women at the AIC and 59 men who presented at the clinic of the UCSF Oral AIDS Center (OAC) was kept. Kaposi's sarcoma lesions on the skin and the oral mucosa are described in detail.
Results: In the AIC, 173 patients had Kaposi's sarcoma on physical exam: trunk 52%, leg 45%, arm 38%, face 33%, and oral cavity 40%. Of the 69 with oral KS at the AIC the other locations were: trunk 54%, leg 47%, arm 44%, face 42%, a similar proportion and distribution to those without oral KS. 15% with oral KS already had an episode of Pneumocystis carinii pneumonia (PCP) while 18% of those without oral KS had prior PCP. KS occurred initially in the mouths of 25/59 (42%) of the patients studied at the OAC. Oral KS was the first AIDS diagnosis in 13/59 (22%) of these patients. The palate was involved in 97% of the cases. Hairy leukoplakia, candidiasis, or both were seen in 74% of these patients and periodontal disease in 26% of these patients.
Conclusion Visceral KS, involving bowel and lung is associated with more rapidly progressive disease. In 42% of the patients at the OAC, oral lesions were their first presentation of KS and in 22%, it gave the first diagnosis of AIDS. Oral KS seems to fit the timing of skin involvement, both in terms of prior AIDS complications and severity of concomitant lesions. Supported by NIH DE PO1-07946.

Th.B.P.341 CLINICAL ASPECTS AND TREATMENT OF ORAL/OROPHARYNGEAL KAPOSI'S SARCOMA

Ficarra, G., Silverman, S., Lozada-Nur, F., Berson, A.M., Quivey, J.M., Migliorati, C.A., Sooy, D.D. Schools of Dentistry and Medicine, University of California, San Francisco, California USA

Objectives. To describe clinical characteristics and treatment of patients with oral Kaposi's Sarcoma (KS).
Methods. Between 1982 and 1987 134 homosexual/bisexual men with oral/oropharyngeal KS were evaluated at the University of California Medical Center, San Francisco.
Results. Median age was 34 and 3 were intravenous drug abusers. Palate and gingiva were the most common sites. Thirty-six had sufficient signs/symptoms (pain, growth, bleeding) associated with their oral KS to require treatment. In 29 oral KS was the first sign of AIDS. Sixty-one had concomitant skin and/or visceral lesions that at this time did not demand therapy. Thirty-four were treated by external radiation using 150 cGy fractions to a total dose of 1500 to the oral lesion(s). All 34 had regression of signs and resolution of symptoms. Two were controlled by CO_2 laser and intralesional vinblastine injections.
Conclusion. Oral KS is a common site of occurrence and may be the first sign of AIDS. Because of significant symptoms and disruption of function, treatment is often indicated. External radiation therapy is an effective form of palliative management in which beneficial effects far exceed adverse reactions.

Th.B.P.342 ORAL HYPERPIGMENTATION ASSOCIATED WITH HIV INFECTION.

Langford, Angelika[1]; Kunze, R.[2], Groth, A.[1], Gelderblom, H.[2], Pohle, H.D.[3], Reichart, P.[1]
Free University[1], Robert-Koch-Inst.[2], Rudolf-Virchow Univ.[3], D-1-Berlin 65, FRG.

Objective: To characterize the clinical and morphological features of hyperpigmentations (h.p.) observed on the oral mucosa of 15 non-smoking HIV-infected patients, biopsies of h.p. (HIV+ n=10; HIV- n=5) and of normal oral mucosa (o.m.) (HIV+ n=5; HIV- n=5) were examined.
Methods: Light microscopy (LM): H&E, Fe2 and Fe3, silverimpregnation. Electron microscopy (EM). Immunohistochemistry (IMHAPAAP): antibodies against CD1, CD4, CD8, CD25, IgA2, TAC and transferrin receptor (ATR).
Results: Localisation of h.p. in HIV+: pl. buccale, palate, gingiva, tongue, extraoral (face, hands, finger/toe nails). During observation time (avge. 8.2 mths.) the size of h.p. in HIV+ increased in 3 pat., 2 of them (AIDS) died, 1 pat. developed AIDS. LM/EM of h.p. (HIV-/HIV+): accumulation of melanosomes within keratinocytes/melanocytes of the basal/superficial cell layers, in fibroblasts/phagocytes of the connective tissue (c.t.). IM: comparison h.p. HIV-/HIV+: the number of CD4+ (3 times), HLA DR+ (4 times) and CD8+ (5 times) cells was increased within c.t.(HIV+). Within c.t. of h.p. (HIV+) only single cells stained + for CD25, TAC receptor, ATR and IgA2. Compared with h.p. (HIV-) and with o.m. (HIV+) the number of CD1+ cells within c.t. of h.p. (HIV+) was markedly increased, while their number within the epithelium was comparable.
Conclusion: The high imbalance of distribution and status of local immunocytes in h.p. (HIV+) may reflect the functional impairment of the oral mucosa. The sudden onset of melanin deposition might be caused by inflammatory/postinflammatory reactions and seems to be correlated with the progression of AIDS manifestation.

Th.B.P.343 ORAL HAIRY LEUKOPLAKIA: CLINICAL BEHAVIOR AND TREATMENT RESULTS

Gaglioti, Domenico; Ficarra,G.; Di Pietro, M.; Paci, P.; Ravina, A.
University of Florence and USL 10/D, Florence, Italy.

Objective. To report on the clinical behavior and treatment results of oral hairy leukoplakia (OHL).
Methods. Appearance of OHL and its clinical behavior were correlated to the T4-cell count in 64 HIV-1 infected patients (pts). In 20 pts treatment response to oral acyclovir was also evaluated. Median follow-up was of 12 months (3-24).
Results. In 64 pts the median T4-cell count, at the appearance of OHL, was of 390 cells/mm^3 (16-1626). In several pts, OHL appeared after a progressive declining of T4-cell count. 25 pts received no specific treatment. Of these, 6/25 showed spontaneous remission of OHL, 6/25 ciclic size variation, 7/25 progression and 11/25 no change. Remission and size variation were associated with incisional biopsy and fluctuation of T4-cell count. Oral acyclovir (1600 mg/d for 14 days) in a open trial determined an objective response (CR=6;PR=8) in 14/20 pts. Median duration of response was 6.5 months (2-11).
Conclusion. Declining level of T4-cells influences the appearance and clinical behavior of OHL. Depletion of T4-cells may facilitate the replication of Epstein-Barr virus (EBV) within the lingual epithelium. Oral acyclovir is an effective therapy of OHL. This favors the pathogenetic role of EBV.
This study is supported by a grant from the Regione Toscana-Progetto HIV.

Th.B.P.344 SALIVARY SIgA AND HIV INFECTION

Sinicco,Alessandro;Moniaci,D.;Greco,D.;Raiteri,R. and Marietti,G..
University of Turin,Turin,Italy.

Objective. To determine the salivary SIgA levels during the HIV infection and evaluate their possible role in the control of oral HIV-related lesions (OHRL).
Methods. 93 subjects were studied: 72 AbHIV+ and 21 healthy controls (H.C.). 32 AbHIV+ didn't show OHRL, 25 were affected by oral candidiasis and 15 by hairy leukoplakia (H.L.). SIgA RID-plates, containing a monospecific anti-secretory component antiserum, were used to evaluate SIgA. IgM and IgA immunoprecipitation allowed to exclude that free secretory component and /or SIgM presence could distort our results. Total salivary proteins (T.P.) and albumine were also tested to exclude the phlogosis influence. Mean value for every patient group are reported in the table.

Results. GROUPS	SIgA (mg%)	T.P. (mg%)	SIgA/IgA
H.C.	30.8±13.2	162.0±43.3	2.8±0.4
AbHIV+ without lesions	45.4±22.4	266.7±88.9	3.6±2.3
AbHIV+ with oral cand.	48.9±17.5	252.4±78.0	3.9±2.3
AbHIV+ with H.L.	64.5±27.2	279.0±57.1	3.1±1.4

Conclusion. A significant SIgA increase appeared in AbHIV+ compared with H.C.. No difference resulted between patients with or without OHRL. The lack of significant difference in the SIgA synthesis shows the minor role of the local humoral response in the control of these lesions. On the contrary, the strict relation ship between circulating CD4+ decrease and OHRL emphatized the cell-mediated immune response importance also in the oral cavity.

Th.B.P.345 OCCURENCE OF ORAL PATHOLOGY AMONG DIFFERENT RISK GROUPS OF HIV INFECTED PATIENTS

Loeb, I*.; Prieels, F*.; De Wit, Stéphane**; Clumeck, N**.
Division of *Stomatology and **Infectious Diseases, St Pierre University Hospital, Brussels, Belgium.

During a 6-year period, 700 HIV patients (P) were examinated; 73% male and 27% female. Risk factors of acquisition of HIV infection were: homosexual or bisexual (homo): 38.8%, African (Afr): 35%, IV drug abusers (IVDA): 14.4%, heterosexual (hetero): 9.7%, unknown (unk): 1.4%, blood transfusion (blood): 0.7%. Clinical stage and immunological status were comparable in all risk groups. Among those 700 P, 300 (43%) presented at least one oral lesion (1 OL). The most frequent findings were: candidiasis (Cand), hairy leukoplakia (HL), periodontal diseases (PD), Kaposi's sarcoma (KS) and recurrent aphtous ulcerations (RAU). Occurence of oral lesions:

Risk factor	P Nb	1 OL	Cand	HL	PD	KS	RAU
Homo	271 P	144 P	59 P	34 P	30 P	13 P	8 P
Afr	245 P	84 P	54 P	6 P	2 P	8 P	7 P
IVDA	101 P	44 P	21 P	7 P	8 P	-	-
Hetero	68 P	28 P	18 P	3 P	1 P	-	-
Unk	10 P	-	-	-	-	-	-
Blood	5 P	-	-	-	-	-	-

In conclusion : 1) Prevalence of all oral lesions is significantly greater in the homosexual group (p 0.001). 2) Hairy leukoplakia and periodontal diseases are two oral lesions which appear preferentially in the homosexual group (p 0.001).

Th.B.P.346 ORAL MANIFESTATIONS OF HIV INFECTION IN ABIDJAN, COTE D'IVOIRE

Likimani, Soniato*; De Cock K.M.*; Green T.L.**; Colebunders R.*; Odehouri, K*; Greenspan, JS** et al.
*CDC/WHO. **Oral AIDS Center University of California, San Francisco, San Francisco, CA, U.S.A.

Objective: To describe oral manifestations associated with HIV infection in hospitalized patients in Abidjan, Cote D'Ivoire.
Methods. Two hundred and fifty-six hospitalized patients (Internal Medicine, Pulmonary Medicine, Infectious Diseases, Dermatology, Gynecology) had a medical, including oral, examination, and were tested for HIV-1 and HIV-2 infection. Clinically significant oral lesions were biopsied for histologic examination.
Results. Fifty-two percent of sera were repeatedly reactive on HIV-1 and/or HIV-2 ELISA. The seroprevalence for HIV-1 and/or HIV-2 infection was higher in males (63%) than females (36%). Oral candidiasis was more frequent in HIV+ve (64/130) than in HIV-ve (21/121) patients (OR - 4.62; p<10-7). For diagnosing HIV infection, oral candidiasis was 49% sensitive, 83% specific, and had a positive predictive value of 75%. No association was found between oral candidiasis and the taking of antibiotics or corticosteroids. Hairy leukoplakia (HL) was suspected clinically in 18/130 HIV/ELISA+ and in 11/121 HIV/ELISA-ve patients (NS). In 17/19 (90%) biopsies taken HL was histologically confirmed. Twelve (63%) of the confirmed HL cases were HIV/ELISA+ve. The predictive value of HL was increased to 71% by histological confirmation.
Conclusions. (1) Oral candidiasis is highly predictive for HIV infection in African patients; (2) HL occurs in African patients with HIV infection.

Th.B.P.347 NATURAL HISTORY OF HIV-ASSOCIATED SALIVARY GLAND DISEASE.

Schiødt,Morten*+;Greenspan,D.*;Dodd,C.*;Chernoff,D.*;Wara, D.*;Leggott,P.*;Hollander,H.* and Greenspan,J.*. *Oral AIDS Ctr, UCSF, San Francisco, CA, USA, +Univ.Hosp. & Dental Coll.,Copenh.,Denmark.

Objective. To describe the natural history of HIV-associated salivary gland disease (HIV-SGD), i.e., presence of salivary gland enlargement and/or xerostomia in HIV infection.
Methods. In 12 patients with HIV-SGD (1 child, 11 adults) followed for a median of 13 months we assessed symptoms, stage of HIV disease, resting whole salivary (RWS) flow rate (FR), stimulated parotid (SP) FR, and immune status (T4, T4/T8). The salivary FRs of the 9 with parotid gland enlargement (PGE) were compared with those of a control group of HIV infected adults without HIV-SGD but with a similar degree of immune deficiency.
Results. The symptoms of dry mouth and the parotid gland enlargement (PGE) were generally unchanged without treatment. PGE disappeared in 3 patients taking various medications (steroids, zidovudine). Acyclovir did not change the PGE in 2 patients. Patients with PGE had significantly lower salivary flow than the control group (P<0.01).

HIV-SGD patients	1st exam.	Follow-up.
No with AIDS	2/12 (17%)	5/12 (44%)
No with PGE	9	6
Mean T4 cells/mm3,T4/T8	283, 0.41	222, 0.28
Mean RWS FR, ml/min	0.46	0.47 (P>0.05)
SP FR, ml/min/gland	0.17	0.27 (P<0.03)

Conclusion. HIV-SGD is associated with low T4 counts and a high risk of development of AIDS. Patients with PGE have reduced parotid flows compared to HIV+ with similar immune deficiency. Unexpectedly, the salivary flow did not decrease with time in spite of further impaired immune status. This effect may partly be due to the given medications. The pathogenesis of this Sjogren's syndrome-like disease is unknown. Supported by NIH PO1-DE07946,the Danish Med. Res. Council (#12-7499,12-8465), and AIDS Fondet,(DK).

Th.B.P.348 TREATMENT OF HIV+ PATIENTS WITH OROPHARYNGEAL AND/OR OESOPHAGEAL CANDIDIASIS: THE RESULTS OF A D.B. STUDY.

Esposito Roberto; Uberti Foppa, C. and Cernuschi, M.
Clinic of Infectious Diseases, University of Milan, Milan Italy.

Objective. To compare in a double blind randomized trial fluconazole and ketoconazole in the treatment of oropharyngeal and/or oesophageal candidiasis in patients with HIV infection.
Methods. Fifty patients with clinical and microbiologically documented candidiasis and HIV infection received either fluconazole 50 mg once a day and 1 placebo capsule once a day for 28 days or ketoconazole 200 mg capsule twice a day for 28 days. Clinical and microbiological responses were evaluated at 7, 14, 21 and 28 days together with analysis of safety and tolerance.
Results. At the end of treatment, clinical cure was recorded in 91,7% of patients treated with fluconazole and in 58,3% of patients treated with ketoconazole. A further 4,2% of patients treated with fluconazole and 33,3% of patients treated with ketoconazole was considered clinically improved. The mycological eradication rate was 44% for fluconazole and 41,7% for ketoconazole. The incidence of clinical side effects was similar in both groups (8%). The incidence of treatment-related laboratory test abnormalities was higher for the patients treated with ketoconazole (elevated values for SGOT in 4 cases and for SGPT in 3 cases vs. 2 cases of elevation of SGOT and 2 cases of elevation of SGPT).
Conclusion. In oropharyngeal and/or oesophageal candidiasis associated with HIV infection, fluconazole appears to be clinically more effective than ketoconazole. In the study no significative mycological differences are observed between the two drugs. Fluconazole seems better tolerated than ketoconazole.

Th.B.P.349 CARBON DIOXIDE LASER TREATMENT OF ORAL KAPOSI'S SARCOMA.

Hadderingh, Roel J., Meulen, F.W. van der

Academic Medical Center, University of Amsterdam, the Netherlands.

Objective. The use of the CO_2 laser in the local treatment of oral Kaposi's sarcomas to reduce the morbidity as seen after treatment with radiotherapy and with the same therapeutic results.
Methods. To avoid the severe mucositis as we have seen after radiotherapy of oral Kaposi's sarcomas we have used the CO_2 laser to remove the tumor of the hard and soft palate as well as from the pharynx and larynx. Uptil now we treated 9 patients. Five of them had sarcomas on the hard palate, one on the soft palate, two in the pharynx and one in the larynx. The surgery was done under general anastesia.
Results. Macroscopically we could remove all tumors but pathological examination made clear that in four cases there was a tumor residue. The period of patients stay in our clinic was from 2 till 7 days. The patients could drink immediately after the surgery and their diet could be extended in the following days. The postoperative pain was controlled with small doses of minor analgetics during a maximum of four days. The follow up has been just four months but we haven't seen local tumor recurrences.
Conclusion. The CO_2 laser surgery of oral Kaposi's sarcomas is effective and gives less morbidity, a shorter stay in hospital and less discomfort to the patients than radiotherapy.

Th.B.P.350 PREDOMINANT MICROFLORA OF HIV-RELATED PERIODONTITIS

T.E.RAMS*, MARIO ANDRIOLO, D.FEIK*, S.N. ABEL, T.M. McGIVERN, and J.SLOTS*. *University of Pennsylvania School of Dental Medicine, Philadelphia, PA, USA, and St.Clare's Hospital and Health Center, New York, NY, USA.

Objective. To document the predominant microflora of a rapidly destructive form of periodontitis that has been associated with HIV-infection.
Methods. The subgingival microbiota in 12 HIV-infected males with severe periodontitis and no history of recent systemic antibiotic therapy were examined. Also studied were 5 HIV-related periodontitis patients with a history of recent antibiotic therapy. Subgingival plaque specimens were collected with paper points from diseased and normal sites and transported in VMGA III. The microbial samples were plated on selective and enriched brucella blood agar and incubated in 85% N_2-10% H_2-5% CO_2, and in 10% CO_2.
Results. Actinomyces viscosus was the most frequent subgingival isolate in normal periodontal sites. Periodontitis sites revealed higher mean CFUs and % gram-negative anaerobic rods. Predominant species included Actinobacillus actinomycetemcomitans (mean % of flora in culture-positive patients = 10.6%), Wolinella spp. (8.1%), Peptostreptococcus micros (21.4%), Bacteroides intermedius (15.5%), Fusobacterium spp. (9.3%), and spirochetes (15.2% of microscopic count). Low levels of Candida spp. and enteric gram-negative rods were detected in the subgingival flora of approximately 50% of the patients studied. Patients with recent antibiotic therapy generally had significantly lower proportions of suspected periodontopathic species.
Conclusion. These findings may facilitate clinical management of HIV-related periodontitis and demonstrate that the subgingival flora in HIV-infected persons may serve as a reservoir for pathogenic organisms.

Th.B.P.351 IN SITU CHARACTERIZATION OF THE INFLAMMATORY INFILTRATE IN HIV ASSOCIATED PERIODONTITIS

Stern, Michael; Murray, P.A.; Winkler, J.R.; Williams, C. and Greenspan, J.S.
Oral AIDS Center, University of California, San Francisco, San Francisco, CA, U.S.A.

Objective. The clinical features of HIV associated periodontitis (HIV-P) have been well documented. However, little is known about the immunopathology of this lesion. The purpose of this study is to characterize the mononuclear cell infiltrates in this lesion.
Methods. Thirteen gingival biopsies were obtained from patients with HIV-P. Similarly oriented, serial cryostat sections were stained for MNC subsets using monoclonal antibodies and the indirect immunoperoxidase technique. Antibodies used were specific for pan T-Cells (Leu 4+5b), T-helper (Leu 3a+b), T-suppressor (Leu 2a), B-cells (Leu 14), monocyte/macrophages (Leu M5), Langerhans cells (Leu 6) and cells expressing HLA-Dr. Positive and negative staining cells were counted in corresponding areas of each section for each antibody. The mean percent of each cell subset was then established for all 13 biopsies.
Results. The mean percentage of cells reacting with antibody specific for T-cells was 31.6%. 23.7% and 15.1% of the cells were identified as T-helper and T-suppressor cells respectively. The mean helper:suppressor ratio was 2.0. Analysis of B-cell infiltration revealed that 11/13 specimens contained only a few (<10) B-cells within the entire section. A mean of 23% of the cells bore markers for the monocyte/macrophage family. 62% of the cells bore HLA-Dr. Uniformly distributed dendritic cells were detected within the epithelium using antibody against both HLA-Dr and Langerhans cell markers.
Conclusion. HIV-P is dominated by T-cells, particularly T helper cells. The majority of the cells express HLA-Dr, thus activated T-cells must represent a substantial proportion of the total T-cells. Monocyte/macrophages are also present in large numbers. There does not appear to be a gross reduction in Langerhans cells. Finally, B-cell infiltration is not a prominent feature of this lesion. Supported by NIH/NIDR PO1 DE-07946

Th.B.P.352 PERIODONTAL DISEASE IN HETEROSEXUAL PATIENTS WITH AIDS

Quart, Arthur M.; Small, C.B. and Klein, R.S.
North Central Bronx Hospital, Albert Einstein College of Medicine, Bronx, New York, U.S.A.

Objective. To determine the prevalence and severity of periodontal disease (PD) in heterosexual patients (pts) with AIDS.
Methods. Consecutive pts with AIDS underwent periodontal and oral examination by a periodontist. Homosexual and bisexual men were excluded from analysis. Abnormal findings were photographed.
Results. 101 AIDS pts were studied. Periodontal findings by risk group and gender are shown: (IVDU = intravenous drug user).

	Number of subjects (percent)			
Extent of PD	IVDU(N=91)	Non-IVDU(N=10)	Male(N=60)	*Female(N=41)
No abnormality	23(25)	1(10)	22(37)	2(5)
Gingivitis only	15(16)	0(0)	11(18)	4(10)
Early PD	19(21)	2(20)	13(22)	8(20)
Moderate PD	15(16)	4(40)	6(10)	13(32)
Advanced PD	19(21)	3(30)	8(13)	14(34)

*PD was significantly more severe in females (odds ratio = 6.1, p<.001)
Periodontal lesions were more severe than those generally seen in non-AIDS pts. 13 pts with PD had severe ulcerative gingival lesions. Additionally 94 pts had candidiasis, 18 had lesions consistent with hairy leukoplakia, 5 lesions suggestive of Kaposi's sarcoma, and 9 oral ulcers.
Conclusion. Periodontal disease is common and severe in heterosexual pts with AIDS. Females have significantly more severe disease. Other oral pathology, especially candidiasis, frequently occurs concurrently.

Th.B.P.353 SALIVARY INHIBITION OF HIV-1 INFECTIVITY IN SERONEGATIVE MEN, WOMEN, AND CHILDREN AND SEROPOSITIVE MEN.

Fox, Philip C.; Wolff, A.; Yeh, C-K.; Atkinson, J.C. and Baum, B.J. CIPCB, NIDR, NIH, Bethesda, MD, U.S.A.

Objective. Inhibition of HIV-1 infectivity by saliva from healthy individuals and HIV-1 infected men was assayed in vitro.
Methods. Unstimulated whole saliva was collected from 25 seronegative persons: 9 men (ages 21-42), 9 women (ages 24-42) and 7 children (4 males, ages 4-11 and 3 females, ages 4-9). Samples were obtained also from 9 seropositive males, ages 33-54. Inhibitory activity was assayed on 2 occasions by measurement of infection of stimulated human peripheral blood lymphocytes by HIV-1 which had been incubated first for 60 minutes with saliva samples or control fluids. Preliminary experiments showed that saliva was not toxic to target lymphocytes.
Results. Inhibition of infectivity was observed in all saliva samples tested. HIV-1 infection was completely inhibited by all salivas from the women and children. Salivas from 6 of the healthy males (66%) completely inhibited infectivity and partial inhibition was found in the remaining 3 samples. The seropositive males salivas had a similar distribution: 7 of 9 (78%) complete and 2 partial inhibition. Dilution of a sample of saliva from a single healthy male showed a dilution-dependent decrease of inhibitory activity, with substantial (~50%) inhibition remaining at a 1:20 dilution.
Conclusion. Salivary HIV-1 inhibitory activity is commonly found in human oral secretions and may play a role in the low risk of HIV-1 transmission by the oral route.

Th.B.P.354 DISINFECTION/STERILIZATION PROTOCOLS RECOMMENDED BY IMPRESSION MANUFACTURERS

Cottone, James A. and Dinyarian, P. University of Texas Health Science Center, San Antonio, Texas, U.S.A.

Objective. To determine the validity of disinfection/sterilization protocols recommended by impression material manufacturers particularly regarding their virucidal activity.
Methods. A mail survey of 6 companies manufacturing 12 commonly used impression materials was conducted. Follow-up questioning by telephone was used to correct incomplete responses. The protocols supplied were reviewed for completeness of documented testing and compliance with basic infection control principles.
Results. Company 1 recommended use of only one chemical disinfectant, which is marketed by another division of the same company. Company 2 recommended any "standard" chemical disinfectant. Companies 3-5 suggested protocols from the published literature. Company 6 provided a protocol based on their studies of their own products, however, only two chemical disinfectants were evaluated with little information provided on methods and materials.
Conclusion. None of the 6 manufacturers recommended a valid infection control protocol for disinfection or sterilization of impressions that did not conflict with basic infection control principles or was adequately documented particularly regarding virucidal efficacy.

Th.B.P.355 FLUCONAZOLE FOR OROPHARYNGEAL CANDIDIASIS IN ANTI-HIV POSITIVE HAEMOPHILIACS

Lim Seng Gee*, Hales, M*, Lee, C A*, O'Doherty, M**, Winter, M***, Kernoff, P B A*
From the Haemophilia Centre, Academic Department of Haematology, Royal Free Hospital*, Hampstead, London, Haemophilia Centre, St Thomas' Hospital**, London, and the Haemophilia Centre, Thanet District General Hospital***, Margate, England UNITED KINGDOM

Objective To assess the efficacy of fluconazole in oropharyngeal candidiasis in symptomatic anti-HIV positive haemophiliacs
Methods All anti-HIV positive haemophiliacs (total 15 currently) who developed oropharyngeal candidiasis on clinical and microbiological criteria were entered into this multicentre study. Those who had predisposing factors to the development of oropharyngeal candidiasis other than HIV disease were excluded from this study. The ages ranged from 25-69yrs (median 32). Initially, all patients entered the treatment phase of the study, where fluconazole was given therapeutically for 14-28 days(median 14) at a dose of 50 mg/d(1 tab). Thereafter, the study was double-blinded to 150 mg fluconazole/placebo weekly for prophylaxis. This phase lasted 6 months unless clinical or microbiological relapse occured, in which case, the patient was exited from the study. This ongoing phase includes regular clinical assessments, mouth swabs, and mouth washings for candida
Results All patients cleared oropharyngeal candidiasis clinically. However, 2 patients showed small residual evidence of candida microbiologically. The prophylactic phase of the study is ongoing and the code has not been broken
Conclusion Fluconazole, a new triazole anti-fungal antibiotic with a long half-life requiring infrequent dosing, has proven to be efficacious in the therapy of oropharyngeal candidiasis and may yet be of considerable benefit in the prophylaxis of oropharyngeal candidiasis (trial ongoing)

Th.B.P.356 ORAL BACTERIAL FLORA: ROLE IN THE INFECTIVITY OF HIV.

D. Ajdukovic*, Q.-L. Liu**, E. Garzon***, D. Meyrand**** and D.D. Pekovic*****.
*Institut Armand-Frappier, Laval, Qc, Canada; **Shanghai Institute of Biological Products, Shanghai, P.R. China; ***Université de Montréal, Montreal; ****Université Laval, Quebec, Qc, Canada; *****Biomedco Canada Inc., Montreal, Quebec, Canada.

Background. The presence of HIV in saliva of infected individuals has been demonstrated before. Although a transmission of HIV by saliva is difficult to prove the transmission of HIV by oral route has recently been reported. Body fluids (saliva or others) which contain infectious AIDS virus, when in contact with activated lymphocytes or other susceptible cells bearing CD4+ receptor (monocytes, macrophages) may affect the transmission of the virus to the susceptible host. Antigenic or mitogenic activation of those cells is the essential prerequisite for such infection to occur.
Objective. To demonstrate activation potential of oral flora of individuals with AIDS as well as of normal individuals.
Methods. Antigenic extracts of bacteria from oral cavity of normal and HIV-infected individuals were used to elicit blastic transformation of normal peripheral blood lymphocytes which were then infected with HIV. The virus multiplication was measured by detection of the reverse transcriptase activity and the expression of viral core protein p24.
Results. The levels of lymphocyte activation and subsequent virus expression was pronounced in HIV-infected individuals to various extent depending upon the evolution of the disease. In normal individuals, blastic transformation was generally suppressed. The study is in progress to evaluate the effects of oral flora of normal individuals who have pathogenic oral flora.

Th.B.P.358 SERUM BETA-2 MICROGLOBULIN AND CD4 LYMPHOCYTE COUNT IN HIV INFECTION

Gold, Julian*; Guinan, JJ*; Morlet, A*; Virtue, L**.
* Albion Street (AIDS) Centre, Sydney Hospital. ** Centre for Immunology, St. Vincent's Hospital, Sydney

Objective The objective of this study was to investigate the temporal association between serum beta-2 microglobulin (β2-M) and HIV disease progression.
Method Serial serum β2-M concentration and T-lymphocyte counts were determined for 73 HIV infected homosexual men over a three year period. Clinical indicators of disease progression are also being obtained.
Results Evidence of deterioration in immune function, as indicated by CD4 counts falling below $400x10^6$/L, has been observed in 54 patients (74%). In 51 of these patients a rise in β2-M above 2.6 mg/L was also observed. In most cases (46/51) a rise in β2-M level either preceded (23/51) or was detected at the same time (23/51) as the fall in CD4 count. A rise in β2-M was observed after a fall in CD4 count in only 5 patients. Of the 19 patients (26%) whose CD4 counts have remained above $400x10^6$/L, 11 had elevated β2-M levels while 8 did not. Progress data on these patients will be presented on completion of the study.
Conclusion The results obtained so far confirm the value of β2-M as an indicator of disease progression in HIV infection and suggest its use as a management tool in early intervention antiviral therapy. Its value as an independent predictor of disease progression will become more evident when changes in CD4 count over time are considered together with data obtained from the patients' clinical records.

Th.B.P.359 EVOLUTION OF THE CD4 4B4 AND CD4 2H4 LYMPHOCYTE SUBSETS DURING HIV-INFECTION.

Vandercam B., Senagui D., Cahill M., Sech F., Omar M., Fernez F., Latinne D., Debruyère M., Departments of Internal Medicine and Haematology.
St-Luc University Hospital, 1200 Brussels, Belgium.

The CD4 T-cell subset may be divided into subpopulations either defined by monoclonal antibodies (Mab) 4B4 or defined by Mab 2H4. CD44B4 T-cells include cells able to help in a humoral immune response and to respond to recall antigens. B-cell dysfunctions have been reported in HIV-patients (pts).
Methods : 49 and 23 pts respectively at stage II-III and IV were included into the study. Mab were supplied by Coulter. Dual color immunofluorescence was performed with EPICS C.
Results (mean) :

	CD4	CD4/CD8	CD4 2H4	CD4 4B4	4B4/CD4	2H4/CD4
Stage II-III	544	0,71	221	258	0,46	0,36
Stage IV	215	0,34	124	158	0,47	0,40

In conclusion, during the progression of HIV-infection, we noticed a progressive destruction of the CD4 cells both CD4 4B4 and CD4 2H4. There was no modifications in 4B4/CD4 or 2H4/CD4 ratios whatever the clinical stages of HIV-infection or the CD4 cells level. So, we found no evidence for the theory that a CD4 subpopulation may be a preferential target of HIV.

Th.B.P.360 INTRA LABORATORY EVALUATION OF A CRYOPROTECTED DOUBLE LABELED PREPARATION FOR FLOW CYTOMETRY

Mandy, Francis*; Bergeron, M.*; McCulloch, B.** and O'Shaughnessy, V. M.* *Bureau of Laboratories and Research Services, Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada. ** Regional Virus Laboratory, Eastern Ontario Childern's Hospital, Smyth Rd., Ottawa, Ontario, Canada.

Objective. To establish whether cryoprotected blood preparations with dual fluorescent labeled monoclonal antibodies against surface antigens (CD4 and CD8) could be useful as an intra laboratory calibration and/or a quality control product. Methods. Cryoprotected preparations were shipped frozen to 19 flow cytometry laboratories (FCL) though continental North America. Each package contained two 0.5 mL cell suspension, instructions and data report sheets. Results. Twelve institutions returned seventeen laboratory reports. The results were from 16 instruments (8 different models) made by two different manufacturers. All reported values fell within 3 standard deviation (SD). 97% of the results were within 2 SD. Over 62% of the results were within 1 SD. The 3% of data over 2 SD were from one instrument model. Conclusion. Cryoprotected human lymphocyte preparations can be utilized as calibration or quality control material for FCL. For universal applications the cooperation of instrument users and manufacturers is essential.

Th.B.P.361 A RAPID VERIFICATION OF MONOCYTE ENRICHMENT/ DEPLETION TECHNIQUE UTILIZING FLOW CYTOMETRY

Mandy, Francis; Sherring, A. and O'Shaughnessy, V.M. Bureau of Laboratories and Research Services, Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada.

Objective. The adherence-to-plastic techniques have been developed to separate monocytes from peripheral blood mononuclear cells (PBMC). Various solid-phase surface depletion methods have been utilized to either deplete or enrich monocytes from PBMC. A rapid verification of the enriching and depleting methods is possible with flow cytometry. Method. The cell suspension containing monocytes was incubated in plastic dishes of various kinds with and without fetal calf serum coating. Recovered cells were incubated with fluorescent labeled monoclonal antibodies specific to monocytes (LeuM3). The monocyte population was determined by flow cytometry. Result. Bacteriological grade plates (BGP) without coating were compared to tissue culture plates (TCP) for efficiency for monocyte enrichment, 75.8% and 41.9% were obtained respectively. For depletion utilizing BGP and TCP the monocyte values were 5% and 9.8% respectively. Conclusion. To enrich monocytes the less expensive method yielded better results. To remove monocytes the more costly plates with fetal calf serum coating is recommended.

Th.B.P.362 LEUKOAGGLUTINATION IN PATIENTS WITH HEMOPHILIA

Riera,N;Felippo,M;Rickard,E;Muchinik,Guillermo;Pérez Bianco, R;deBracco,MM de E
IIHEMA, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective: a) To evaluate the capability of hemophiliacs'(He) sera to agglutinate normal polymorphonuclear (PMN) leukocytes,since antilymphotic antibodies prevalence is greater in He HIV+ than in He HIV-. b) To look for a correlation of leukoagglutination (LA) to circulating immune complexes (CIC) and fibronectin (Fn).
Methods: One hundred ul of 5x10^{6} PMN/ml were incubated with 100 ul of inactivated serum (56°C), diluted 1/10 for 2 hs at 37°C and 18 hs at 4°C, and the percentage of agglutinated PMN was determined. CIC were measured by precipitation with polyethylene glycol 3.5% final concentration. Fn was evaluated by radial immunodiffusion.
Results: LA mean values were significantly higher in He HIV+ than in either He HIV- or normal controls (N) ($p<10^{-7}$). LA % ($\bar{x}\pm$SE): He HIV+: 39±4,n=28; He HIV-: 8± 4,n=21;N:4±1,n=14. LA was observed in 94% He HIV+,in 36% HeHIV- and in 7%N. High values were confirmed for CIC in He HIV+ (OD$_{280}$($\bar{x}\pm$SE): 0.41± 0.03,n=28) when compared with He HIV- and N(OD$_{280}$($\bar{x}\pm$SE)He HIV-:0.26± 0.03,n=21;N:0.20±0.01,n=14), but there was no statistic correlation between LA and CIC values. Seric Fn concentration was not different in these groups ug Fn/ml ($\bar{x}\pm$ SE):He HIV+: 208± 17,n=19;He HIV-:206± 35,n=14;N:222±25,n=10).
Conclusions: The presence of LA in He is independent of treatment-provoked antigenic stimulation, of CIC and Fn levels. However, LA could be associated with HIV-infection.

Th.B.P.363 INTRA BLOOD-BRAIN-BARRIER TOTAL IgG SYNTHESIS IN PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS INFECTION.

A. Sena*, V. Ferret-Sena*, A. de Sousa*, F. Maltez*, A. Morgado* and R. Proença*. Faculdade de Ciências Médicas, Centro de Diagnóstico Computorizado e Hospital Curry Cabral, 1100 Lisboa, Portugal.

Cerebrospinal fluid (CSF) protein profile was studied in 15 patients with human immunodeficiency virus (HIV) infection and clinical evidence of central nervous system (CNS) disorder. Total CSF and serum protein and IgG concentrations were determined and the CSF/serum albumin quotient was measured as an index of blood-brain-barrier function. Results were plotted into a diagram (1) and intra blodd-brain-barrier total IgG synthesis was quantified according to three formulas (2, 3, 4). Reiber's diagram detected an abnormal protein profile in 14 of 15 (93%) patients and total IgG synthesis within the CNS was present in 11 of 15 (73%) patients. No correlations were found between those CSF abnormalities and the clinical and CT scanning findings. It is concluded that the study of CSF protein profile is a clinically useful and very sensitive way of testing the development of CNS disorder in patients with HIV infection, the acquired immunodeficiency syndrome (AIDS) or AIDS-related complex.

Th.B.P.364 INCIDENCE OF AUTOANTIBODIES IN HIV INFECTION.

Quaranta,J.F.*; De Matteis,M.*; Casasnovas,C.*; Vivinus,M.*; Cassuto,J.P.**; Dellamonica,Pierre***.
* Laboratoire d'Immunologie, ** Médecine Interne, *** Maladies Infectieuses, C.H.R.U. Nice, France.

Objective. Dysimmune state (e.g. T4 lymphopenia and hyperimmunoglobulinemia) in seropositive HIV patients (HIV+) now are well known. We here reported the incidence of autoantibodies (AAb) in a series of 87 patients.
Methods. AAb were detected by indirect immunofluorescence, excepted for anti-HLA Ab (microlymphocytotoxicity), rheumatoid factor (ELISA), circulating immune complexes (CIC) (latex immunonephelometry).
Results. Anti-smooth muscle AAb were observed in 34/76 cases (45%). 37/50 sera react with lymphocytes without anti-HLA specificity (from 3 to 90% of the panel, mean = 41.3% with sd = 27.6). Anti-nuclear AAb and anti-thyroid microsomal AAb were always absent (0/87). Rheumatoid factor was only found in 3/59 cases (5%). Anti-epidermal AAb were present in 2/26 cases (7%), anti-keratin in 13/35 (37.1%) and anti-actin in one out of 35 cases (2.8%). CIC have been detected in a large percentage of HIV+ patients : 47/66 (71%).
Conclusion. The polyclonal B-cell activation and diffuse hyperimmunoglobulinemia, well-known features of HIV infection, account for the presence of these autoantibodies and an aberrant B-cell immunoregulation after HIV infection.

Th.B.P.365 LYMPHOCYTES CD4+,BETA 2 MICROGLOBULINE ET NEOPTERINE DANS LE L.C.R. ET LE SANG AU COURS DE L'INFECTION PAR V.I.H.

VERGNE A.†,CAUDIE C.†,BRUN J.**,TOURAINE F.†,LIVROZET J.M.*,QUINCY Cl.†,TOURAINE J.L.*
†Lab.Immunobiologie. Hôpital Neurologique 69394 Lyon Cédex 03. FRANCE.
**Lab.Radioanalyse.Centre méd. nucléaire 69394 Lyon Cédex 03.FRANCE.
* Pavillon P.Hôpital Edouard Herriot 69437 Lyon Cédex 03.FRANCE.

Objectif: Préciser l'intérêt des dosages , dans le LCR et le sang , pour apprécier une éventuelle atteinte neurologique chez les patients avec ARC et SIDA.

Méthodes: Etude chez 45 malades VIH+ (30 SIDA,10 ARC et 5 asymptomatiques) dont 20 présentaient des manifestations neurologiques.Numération des lymphocytes CD4+ et CD8+ (Cytométrie en flux sur EPICS C®) et dosages de la Bêta 2 microglobuline et de la néoptérine (RIA).

Résultats: Nous observons une destruction des lymphocytes CD4+ , une augmentation progressive de la Bêta 2 microglobuline dans le LCR et le sang , quel que soit l'état neurologique. Les taux de néoptérine sont significativement augmentés quand il y a atteinte neurologique au stade SIDA.

Conclusion: Chez les malades avec ARC et SIDA , le marqueur le plus performant pour apprécier l'atteinte neurologique est le taux de néoptérine; les 2 autres paramètres , CD4+ et B2M , sont des marqueurs d'évolutivité de la maladie.

Th.B.P.366 STUDY OF PREDISPOSING FACTORS ON THE SUSCEPTIBILITY OF INDIVIDUALS TO INFECTION BY HIV.

D. Ajdukovic*, Q.-L. Liu**, R. Turcotte*, D.D. Pekovic*** and G. Lamoureux*.
*Institut Armand-Frappier, Laval, Qc. Canada. **Shanghai Institute of Biological Products, Shanghai, P.R. China. ***Biomedco Canada, Inc., Montreal, Quebec, Canada.

Background. Numerous publications suggest an association of tuberculosis (TB) and AIDS. Individuals with active or latent TB may be more susceptible to the infection with HIV. Macrophages (MO) of TB patients even when "cured" have always been found to harbor TB bacilli and may serve as their latent reservoirs. Recent studies indicate that mononuclear phagocytes such as monocytes and macrophages (MNPC) may be subject to a similar strategy to hide HIV from body's immunological mechanism particularly in the early stages of HIV infection and/or in HIV carriers.
Objective. In vitro study of the susceptibility of MNPC of tuberculin positive (TB+) and tuberculin negative (TB-) individuals as well as patients with active TB to the infection by HIV.
Methods. MNPC were isolated and purified from blood of TB+ and TB- individuals as well as from TB-infected patients were infected with HIV, incubated for 7 days, then HIV production amplified in a co-culture with H9 cells for 5 days. The virus was determined by p24 antigen capture assay in the supernatants of broken and unbroken MNPC.
Results. Although the in vitro system employed may not represent a situation in vivo, the MNPC from TB+ individuals showed a higher resistance to infection by and/or production of HIV. Significance of this will be discussed.

Th.B.P.367 RAISED β-2-MICROGLOBULIN LEVELS IN ASYMPTOMATIC PHASE OF THE HIV-1 INFECTION.

Mayer,Vlastimil;Uherová,P.;Schmidtmayerová,H.;Feldes,O.;Mikulecký,M.+;Zachar,V.
Institute of Virology,Slovak Acad.Sciences,Bratislava,Czechoslovakia, +Medical Faculty,Comenius University,Bratislava,Czechoslovakia.

Objective. To define more precisely the individual differences in the course of HIV infection in asymptomatic persons.
Methods. In seropositive(n=19) persons were studied for two years at 6 month intervals absolute CD4+ and CD8+ lymphocyte counts,serum β-2-microglobulin(β2M, RIA),levels of the anti-core, anti-env and neutralizing antibodies(Ab),the HIV core p24 antigenemia.Comparatively also normal healthy persons(n=57),HIV-seronegative homosexual men(n=42) and 27 sera initially reactive in EIA,not confirmed as positive by immunoblot(DuPont).Data were processed by Kruskal-Wallis and Neményi tests.
Results. β2M were higher ($p<0.001$) in seropositive than in seronegative persons and in EIA initially reactive sera than in normal healthy subjects($p<0.05$).β2M levels correlated in the early phase of infection with CD8+ counts,later with the decrease of anti-core Ab and with the antigenemia presence,following closely the p24 concentrations(studied consecutively for 8 months).
Conclusion. β2M quantification,with other markers considered also,appears as valuable forthe HIV infection process monitoring in order to decide about antiviral treatment.

Th.B.P.368 HIV-1 IgG ANTIBODIES IN BREAST MILK: DETECTION METHODS AND CORRELATION WITH SERUM MARKERS

*Ruff, Andrea; *Farzadegan H; **Marzouka J; **Boulos R; *Saah A; *Halsey N; et al.
*Johns Hopkins University, Baltimore, MD; **Centers for Health and Development, Port-au-Prince, Haiti.

Objective. To determine the utility of breast milk analysis in the diagnosis of HIV-1 infection.
Methods. Blood and breast milk specimens were collected from 12 HIV-1 seropositive and 7 seronegative women residing in a periurban Haitian slum. Specimens were tested by Western blot (WB- Biotech, Biorad and Chiron) and p24 antigen capture.
Results. Breast milk specimens from 11 of 12 seropositive women were positive by WB analysis; breast milk and blood WB band concordance was observed in 10 of 11 women. One previously seronegative woman appeared by WB to have seroconverted recently; no WB bands were present in her breast milk. None of the 7 HIV-1 seronegative women had WB bands in their sera or breast milk specimens.
Conclusions. HIV-1 IgG antibodies are present in breast milk of seropositive women. Although WB analysis of breast milk appears to provide a specific method of screening for HIV-1 infections, recent seroconverters may not excrete detectable quantities of IgG HIV-1 antibodies in breast milk.

Th.B.P.369 COMPARISON OF 8ANTI-HIV ENZYMEIMMUNOASSAYS,3HIV ANTIGEN ASSAYS AND 2 WESTERN BLOTS ON A SEROCONVERTER PANEL

Allison A Imrie* and David A Cooper**
*Centre for Immunology,St VincentsHospital**The NationalHealth and Medical Research Council Special Unit in AIDS Epidemiology and Clinical Research, The University of New South Wales,Sydney,Australia

Objective.To compare limits of detection of 8 commercial Anti-HIV EIAs which employ either recombinant or whole virus antigens,and 2 WBs on a seroconverter panel;to compare the performance of 3 antigen assays on these sera
Methods.36 serial serum samples from 3 homosexual males with symptoms of 1° HIV infection collected over a period of 7-90 days after onset of symptoms were tested for Anti-HIV by 8 EIAs,3 Antigen EIAs and 2WBs.A mean of 12 samples were drawn from each subject(range 9-14).The mean time between the last sample negative by all tests and the first sample to be positive by at least one test was 4 days.
Results.Anti-HIV was not detected in any sample collected within one week of onset of symptoms.In the second week(days 8-14)one assay detected anti-HIV in 75% of samples compare with 25% detected by 4 other assays.7 out of 8 assays detected anti-HIV in 100% of samples by day 90.One WB produced a positive result during week 3 while the other assay did not show a clearly positive result until day 49.Indeterminate band profiles(anti-gag,then anti-env and anti-pol)suggestive of early S/C appeared in both assays by the second week following onset of symptoms.No viral specific bands were detected in sera collected within one week following onset of symptoms.
Conclusion.This seroconverter panel allows ranking of 8Anti-HIV assays and 2 WBs according to sensitivity.There is a wide range of detection limits between assays which does not seem to be related to the kind of assay used

Th.B.P.370 DETECTION OF HIV ANTIGEN AND HIV CORE ANTIBODY DURING SEROCONVERSION

Allison A. Imrie; Glenn Doherty* and David A. Cooper**
*Centre for Immunology, St. Vincents Hospital **The National Health and Medical Research Council Special Unit in AIDS Epidemiology and Clinical Research, The University of New South Wales, Sydney, Australia

Objective.To assess the incidence of HIV antigen during seroconversion and to investigate the relationship between HIV antigen and anti-Core antibody
Methods.903 serum samples from 124 seroconverting subjects were tested for HIV antigen,antibody and core antibody.A mean of 7.2 sera were drawn from each subject(range 2-36).
Results.18 out of 115subjects had detectable antigen prior to seroconversion. Of the 18 subjects,12(67%)had a time interval between last negative and first positive anti-HIV of less than 40 days.The remaining 6 subjects(33%) had a window period greater than 40 days.In no subject with a window period greater than 320 days was antigen detected prior to seroconversion.The majority of subjects((96%) with core antibody at or prior to S/C were not antigenaemic at this time;33% of subjects in whom appearance of core antibody delayed post seroconversion were antigenaemic at the time of seroconversion and all patients who demonstrate a persistent antigenaemia post seroconversion do not develop a detectable core antibody.
Conclusion. HIV antigen is detectable more frequently in seronegative subjects who susequently seroconvert when the window period between the last antibody negative and the first antibody positive sample is narrow.In no subject with a window period greater than 320 days was antigen detected prior to seroconversion.Antigenaemia at or post seroconversion is linked to a delayed core antibody response at this time.

Th.B.P.371 SENSITIVE DETECTION OF HIV-1 ANTIBODY WITH A PEPTIDE-BASED ELISA IN TWO SEROCONVERSION PANELS

Lacroix, Martial*; Dwyer, R.J.* and Fauvel, M.**
*IAF BioChem International Inc., Montréal, Canada, H7V 1B7;
**Laboratoire de Santé Publique du Québec, Montréal, Canada

Objective: Compare the ability of a new peptide-based ELISA with RIPA for the detection of early antibodies to HIV-1.
Methods: Serum samples are from two seroconversion panels. Each specimen was carefully characterised for the presence or absence of antibodies to HIV by the FDA licensed ELISA test kits then available as well as by IFA and WB. IAF BioChem's combined HIV-1/HIV-2 antibody detection kit is a peptide-based ELISA whose characteristics and performance are described elsewhere at this meeting. RIPA procedures are as described (Ozanne and Fauvel, J. Clin. Microbiol. 26: 1496, 1988).
Results:

Serum id.	BioChem ELISA	RIPA	Remarks
BBI-A01	NEG	NEG	
BBI-A02	NEG	NEG	
BBI-A03	POS	VERY WEAK POS	gp only (W.B. neg.)
BBI-C22	IND	VERY WEAK POS	gp only (W.B. neg.)
BBI-C23	POS	WEAK POS	gp only (W.B. neg.)
BBI-C24	POS	WEAK POS	gp only (W.B. neg.)

Conclusion: IAF BioChem's ELISA is more sensitive than WB and viral lysate ELISA and is comparable to RIPA in the early detection of antibodies to viral glycoproteins.

Th.B.P.372 IMMUNOCOMPETENT CELLS IN LIVERS OF CHILDREN WITH AIDS.

Thomas, P*; Greco, M.Alba*; Kahn, E§; Magid, M†; Mahnovski, V*; Anderson, V#. *New York University, NY NY §North Shore University Hospital, Manhasset, NY; †Cornell Medical Center,NY NY; °Childrens Hospital, LA, CA; #Pediatric AIDS Group, USA

Objective. To define the inflammatory cells, especially macrophages and antigen presenting cells (APCs) in livers of children dying of AIDS. Method. Seventeen livers from autopsies of AIDS children aged 2.5 mos to 7 yrs and sections from 11 non-AIDS controls were studied by immunohistochemistry. All had hepatomegaly and 4 had clinically evident liver disease. Results. Mild portal inflammation = 9(53%);moderate = 5(29%);severe = 3 (18%, 1 with lymphoid aggregate). Two cases, 1 mild/1 severe, had MAI granulomas. Lobular involvement was seen in 3 (18%, 1 with lymphoid nodules, 2 with granulomas). Antigen expression was as follows (# of cases):

	LCA	B cell	T cell	S-100	HLA DR	MS	LYSO	A1ACT
Lymphocytes	+(15)	+(1)	+(17)	-	-	-	-	-
Macrophages	-	-	-	*	-	+(17)	+(17)	+(15)
APCs	-	-	-	+(1)†	+(3)	+(3)	+(3)	+(3)
Kupffer cells	-	-	-	*	*	+(17)	+(17)	+(17)

* MAI organisms show weak S-100 (+); rare Kupffer cells (+) for S-100 and HLA-DR. † Lymphoid aggregates mimicked mature follicles (i.e., distribution of B,T, and APCs). MS=macrophage specifib; A1ACT=alpha-1-antichymotrypsin. Conclusion. T cells are the predominant lymphocytes in hepatic infiltrates. APCs are present in lymphoid nodules and granulomas; HLA-DR is more sensitive in detecting them. When lymphoid aggregates are seen, mature follicles are recapitulated.

Neurologie
Neurology

Th.B.P.374 NEUROLOGICAL MANIFESTATIONS IN PATIENTS WITH HUMAN IMMUNO DEFICIENCY VIRUS INFECTION

Goh, Beng*; Estreich, S*; Forster, G.E.*; Kennard, C**; Swash, M.**.
*Whitechapel Clinic and ** Department of Neurology, The London Hospital, London, England. UNITED KINGDOM

Objective: To determine the prevalence of neurological manifestations in patients infected with HIV.
Methods: 111 patients infected with HIV were analysed retrospectively with respect to age, sex, risk factors, stage of HIV infection, type and cause of neurological manifestations. Follow-up was from 6 - 29 months.
Results: 18 neurological episodes were identified in 17 (15%) of 111 patients: 10 of 29 patients with AIDS, two of 19 with AIDS-related complex, one of 28 with persistent generalised lymphadenopathy and four of 35 who were otherwise asymptomatic. Central nervous system involvement included three with HIV-related encephalopathy, three with CMV retinitis, one with grand mal fits associated with toxoplasmosis, one with oculomotor neuropathy, left hemiplegia and Parkinsonism associated with toxoplasmosis, five with Bell's palsy (two in association with herpes zoster) and one with blindness from necrosis of the optic chiasma in assocation with progressive multifocal leukoencephalopathy. Three patients had peripheral neuropathy.
Conclusion: Neurological manifestations occurred in 15% of patients; cranial neuropathies were common and rare complications such as Parkinsonism and optic chiasmal necrosis were seen.

Th.B.P.376 IMPAIRED MOTOR PERFORMANCE OF HIV-1 INFECTED PATIENTS IS NOT DUE TO SIMPLE FATIGUE

Keilp, John G; Sadler, AE; Wolf, L; Brew, BJ; Price, RW; Sidtis, JJ. Memorial Sloan-Kettering Cancer Center, NY, NY, USA.

Objective: To determine if impaired motor performance (finger tapping)in HIV-1 infected patients is related to the effects of fatigue.
Methods: 129 untreated HIV-1 infected patients at varying AIDS Dementia Complex (ADC) stages were evaluated with the Neuro-AIDS Study Group neurological history, exam, and neuropsychological battery. Subjects were staged as normal, mild, or moderate with respect to severity of ADC-related motor impairments. In order to assess susceptibility to fatigue, subjects were administered a modified finger tapping task: five 10-second trials spaced with no more than a 10-second pause between them.
Results: Finger tapping performance with both dominant [F(2,127)=31.80, p<.001] and non-dominant hands [F(2,127)=30.00,p<.001] declined with increasing severity of ADC-related motor dysfunction, with marked differences among the groups apparent on both hands from the first trial [F(2,129)=43.82, p<.001]. Only the normal and mild patients'performance declined on later trials; patients with moderate motor dysfunction showed no change in performance ("fatigue effect") over the five trials [F(4,24)=0.50, p=.735].
Conclusions: With increasing motor dysfunction due to ADC, poor motor performance appears to be related to deterioration of the capacity of the motor system, not simply to susceptibility to fatigue effects.

Th.B.P.373 SERIAL IMMUNOLOGIC STUDIES AS AN INDICATOR OF PROGRESSION TO AIDS IN A COHORT OF MALE SEXUAL PARTNERS OF MEN WITH HIV DISEASE

Read, Stanley, Coates, R., Farewell, V., Klein, M., MacFadden, D., Calzavara, L., et al.,University of Toronto, Toronto, Canada

Objective: To compare serial immune parameters in men who have developed AIDS.with those of men who are seropositive and seronegative controls.
Methods: At recruitment, 143/249 men were seropositive and 16 subsequently seroconverted. At the time of this analysis, 24 had developed AIDS. Serial routine hematology, T-lymphocyte subsets, blastogenic responses and quantitative immunoglobulins were done on all members of the cohort. Data was analysed based on comparison of values at intervals from estimated time of infection.
Results: There were significant differences in absolute T4 counts, T4/T8 ratios, response to PHA, IgM and IgA levels between seronegatives and seropositives who went on to develop AIDS. Most of these differences did not increase with time but were significant at the time of entry into the study. Only IgA levels showed a significant increase in the last 4 months in the group developing AIDS.
Conclusions: Differences in immune parameters between groups of uninfected, infected and progression to AIDS generally are unchanged on serial determinations. Also, variability in serial test results in an individual makes the use of a single test of limited value in prognosis.

Th.B.P.375 AIDS-RELATED NEUROLOGICAL ILLNESS IN TWO U.S. CITIES: A COMPARISON OF SIMILAR POPULATIONS

Stephen Grohmann*; Levy, R.*; Bredesen, D.**; Rosenblum, M.**; Cohen, B.*; Von Roenn, J.*; and Murphy, R.* *Northwestern University Medical School, Chicago, IL USA
**University of California, San Francisco, CA USA

To address the question of regional and risk group related variations in the incidence of AIDS-related neurological illness, we retrospectively evaluated the nature and frequency of neurological illness in two similar patient populations treated in University hospitals in San Francisco, California (SF) and Chicago, Illinois (CHI). In both SF and CHI, the predominant risk group for the acquisition of HIV infection was homosexual or bisexual exposure (99% and 79%, respectively), other major risk factors included IV drug abuse (2% SF, 7% CHI) and transfusion (>1% SF, 1% CHI). Signs or symptoms of neurologic illness were observed in 482 of 1286 (37%) of patients in SF and in 58 of 205 (28%) of patients in CHI. Peripheral nervous system symptoms were noted in 79 patients in SF (6.1%) and in 20 patients in CHI (9.8%), while CNS dysfunction was observed in 474 patients in SF (37%) and in 41 patients in CHI (20%). Major specific pathologic diagnoses included (SF;CHI): HIV encephalopathy (100, 28%; 20, 34%), cryptococcal meningitis (68, 14%; 4, 7%), toxoplasmosis (53, 11%; 7, 12%), primary CNS lymphoma (25, 5%; 2, 3%) and PML (8, 2%; 3, 5%). Less common diagnoses included HSV, CMV or HVZ encephalitis (28, 5.8%; 1, 1.7%) and rare cases of CNS tuberculoma, and intracerebral hemorrhage secondary to thrombocytopenia.

The data reflects a trend toward increasing neurologic illness with decreased T4 cell count. The mean T4 cell count in non-neurologically symptomatic patients was 143.5 + 14.4 while in neurologically symptomatic patients, the mean T4 count was 96.1 + 14.0. This trend may suggest that immunosuppression is a significant factor in the development of AIDS-related neurologic illness. The data further suggests that populations that are similar with respect to risk group, despite geographical location, may well have similar rates of neurologic disease.

Th.B.P.377 "EXPRESSION NEUROPSYCHIATRIQUES DU SIDA AU SENEGAL"

D'ALMEIDA L. DIOP A.G., A POVO C.
C.H.U. DE FANN- DAKAR (SENEGAL)

OBJECTIFS: Les divers effets dévastateurs du SIDA impose la nécessité délargir son approche biomédicale à des données sociales, culturelles par l'étude des problèmes psychiatriques et neurologiques, jusqu'ici absents des recherches sur le SIDA au Sénégal.
METHODES: les 6 cas de l'étude ont été analysés à partir:
- d'un guide d'observation neuropsychiatrique inspiré de L'A.M.D.P. et de la B.P.R.S.;
- d'un examen clinique neurologique;
- d'un examen clinique psychiatrique.
RESULTATS: Il a été noté un polymorhisme du tableau neurologique avec diverses topographies. Il n'existe pas de manifestations psychiatriques propres au SIDA.
CONCLUSIONS: Ces conclusions ne concernent que la population observée. Elles doivent être comparées, dans un an, à une population sidéenne plus large.

Nutrition

Th.B.P.378 NUTRITIONAL FACTORS ASSOCIATED WITH AIDS

Zumwalt, Sally A.* and Schmidt, R. M.**. Center for Preventive Medicine and Health Research, *San Francisco State University and *Pacific Presbyterian Medical Center, San Francisco, California, USA

Objective. To evaluate the nutritional status of patients with ARC and AIDS. Methods. Nutritional status, laboratory values for serum albumin, serum total protein and serum cholesterol, height and weight, medical history, and use of prescribed medications, vitamins, minerals and alternative therapies were evaluated in 20 ARC and 20 AIDS male patients. Twenty healthy males from the Health Watch program, a longitudinal prospective study of healthy aging, were used as a control group. Participants completed the Health Watch Questionnaire which provides quantitative scores of health status and lifestyle habits in 7 areas: nutrition, medical events, general well-being, psychological well-being, physical activity, alcohol use and smoking. ARC and AIDS patients were followed at 3 month intervals for a period of 6 months.
Results. Mean weight loss, deficiency in calories in comparison to the mean total energy expenditure (TEE), and serum albumin and cholesterol levels were significantly decreased in patients with ARC and AIDS. Health Watch Questionnaire scores were significantly lower for ARC patients than controls in all areas except alcohol use. AIDS patients achieved better scores than ARC patients, but had significantly lower scores in medical events, nutrition, psychological well-being and general well-being when compared to controls.
Conclusion. Malnutrition was shown to be associated with the laboratory values of serum albumin and cholesterol in patients with ARC or AIDS, these laboratory tests can be used as markers of progression of HIV infection. We recommend that nutrition, health behavior, serum albumin and serum cholesterol assessments be incorporated into current longitudinal studies on AIDS

Th.B.P.380 NUTRITIONAL ASPECTS OF AIDS PATIENTS IN AN INNER CITY CLINIC.

Forrester, C.*, Koller, S.**, Perez, G.*, Perez, E.*, Slim, Jihad*
*Saint Michael's Medical Center, Newark, New Jersey, U.S.A.
**University of Medicine & Dentistry, Newark, New Jersey, U.S.A.

Objective: Assessment of nurtition (Nut) practices and identification of patients at high risk for potential hypervitaminosis syndromes.
Methods: During a one week period in August 1988, clients (C) attending an inner city HIV clinic, participated in an anonymous survey of Nut practices.
Results: 25 C participated, demographics reflected clinic make-up: 60% I.V.D.U., 12% homosexual, 20% sex partners of I.V.D.U. 40% were using liquid nutritional supplement (NS). 76% were using vitamins (Vit) regularly, only half of these were ordered and monitored by M.D.s. 48% were using 2 or more Vit/day. 16% were using herbal teas, roots and Vit from Health Food Stores. 40% C had lost more than 5 kg in the last six months, 90% of these were using Vit, 70% were using 2 or more Vit/day. 72% of C were dissatisfied with Nut information provided by clinic. Only 12% reported that Nut had been discussed during either of the last 2 clinic visits. C used NS and Vit rather than dietary manipulation as a means of improving Nut.
Conclusion: C. with significant weight loss may be using multiple Vit and may represent a group at risk of Vit toxicity.

Th.B.P.382

Th.B.P.379 THE CHALLENGE OF NUTRITIONAL CARE OF PATIENTS WITH AIDS

Chrysomilides, Sonia, St. Paul's Hospital, Vancouver, B.C. Canada

Objective. To identify different nutritional complications present at different stages of HIV infection.
Results. Nutritional complications can be best described according to the following patient groups:

- Asymptomatic: only a few nutritional problems occur, the individual needs extensive nutrition education to prevent the development of malnutrition.
- Constitutional disease: the individual experiences fever, weight loss and diarrhea. A high protein high calorie diet, and for some individuals, one that is lactose free, restricted fibre and restricted fat, with complete supplements, is necessary.
- Opportunistic infections and malignancy: the individual experiences a number of nutritional complications, which require special nutritional care and attention. A number of gastrointestinal, liver or kidney problems dictate different dietary regimens and/or modifications. When oral and esophageal lesions are present, a soft, semi-soft or liquid diet would be suggested, avoiding citrus fruit, spicy, very hot or very cold foods.
- Food and drug interactions should be considered also at all times.

Conclusion. The maintenance of adequate nutrition in patients with AIDS is a major concern. However, the care plan cannot be generalized. The significant nutritional effects of AIDS challenge all dietitians who play a role in the care of AIDS patients, and requires that they understand the disease processs and its implications on nutritional status.

Th.B.P.381 DIETARY INTERVENTION IN KAPOSI'S SARCOMA PATIENTS.

Sam Golden*, Paul Kahl*, and Barry Sears**. *Medica, Homestead, PA 15220 and **BioSyn, Marblehead, MA U.S.A.

Objective. To determine the role of dietary intervention in Kaposi's sarcoma patients.
Methods. An open study was conducted with 5 patients with Kaposi's sarcoma (KS) to determine the role dietary intervention might play in this clinical manifestation of AIDS. The dietary intervention consisted of a combination of metabolically activated essential fatty acids formulated to increase the tissue levels of dihomo gamma linolenic acid (DGLA) relative to arachidonic acid (AA) in order to influence prostaglandin production.
Results. In patient #1 with early lesions, total regression was seen within 2 months. Biopsies taken four months since lesion regression demonstrated no evidence of active KS lesions. Patient #2 was being treated with AZT which had decreased the rate of lesion formation prior to supplementation. With dietary supplementation, the most recent lesions were observed to regress within 2 months. Biopsies in the areas of the regressed lesions indicate no evidence of active KS. There has been no change in the long term lesions. Patient #3 demonstrated a 50% reduction of his most recent lesions. Patients #4 and #5 who had much more advanced lesions, have not yet seen lesion regression. Patient #1 has been on the dietary supplementation program for 6 months, whereas Patients #2-5 have been on the dietary supplementation program for 2 months.
Conclusion. This initial data indicates that appropriate dietary intervention may play a role for regression of early Kaposi's sarcoma lesions. Potential mechanisms will be discussed.

B.501 SEMEN BANKS/EMBRYO BANKS: POTENTIAL HAZARD OF HIV TRANSMISSION: AN OVERVIEW

E.S.E. Hafez
World Federation of Contraceptive Health; Reproductive Health Center, Surfsong Road, Kiawah, SC U.S.A.

Donor artificial insemination (AID) and in vitro fertilization (IVF) using human fresh semen and cryopreserved/thawed semen from HIV-seropositive or asymptomatic donors play a critical role in HIV transmission. HIV and various strains of STD's can adhere to and penetrate the plasma membrane of human sperm head/midpiece. Mammalian sperm can express CD4 epitopes, which are involved in the binding of HIV with other cells. Certain surface proteins, involved in sperm-egg adhesion are attached to sperm plasma membrane via lipid phosphatidylinositol. Replication of HIV and subsequent budding of viron particles may occur within the cytoplasma/nucleus of sperm. HIV transmission from Semen Banks involves antigen cross-linkage among sperm/lymphocyte/NK cells; glyolipid/glycoprotein; and humoral/local immunity against sperm antigen. Other cofactors for HIV transmission inicude mucosal trauma in urogenital tract and its associated lymphoid tissues of semen donors and perhaps host recipients Little is known about the immunopathogenic mechanisms which regulate HIV replication/colonization of HIV in the female/male reproductive tract. HIV-infected sperm transmits HIV to the oocyte at the time of fertilization. As in rodents HIV-infected males can infect both the oocyte at fertilization as well as the fetus/neonate. These phenomena are related to Pediatric AIDS. Future research is needed to evaluate qualitative/quantitative, intermittent/persistent, levels and temporal changes of HIV viron particles in the seminal plasma vs sperm surface membrane

B.502 CONTRACEPTIVES, HIV INFECTIONS AND HETEROSEXUAL TRANSMISSION

Saad Hafez; El Tonsi, H.* and Lotfy, M.**.
Reproductive Health Center, Kiawah Island, SC U.S.A., *World Federation of Health, Egypt, **World Federation of Health, Saudi Arabia.

Contraceptive copper IUD's, contraceptive diaphragms, rubber condoms, and spermicides may produce allergic contact dermatitis in sensitized persons. Rubber chemicals may cause condom dermatitis/diaphragm balanitis in rubber sensitive men, and vulvititis/vaginitis in rubber-sensitive women. Dermatitis may be due to sensitizers in contraceptive spermicides: phenylmercuric acetate, oxyguinoline sulfate, quinine hydrochloride, and hexylresorcinol. Increased blood flow to the uterus and increased cellularity associated with IUD's enhances HIV heterosexual transmission. IUD's cause local damage of endometrial lining, which is a potential entry point for HIV, or a site from which it is transmitted. Cofactors which enhance HIV heterosexual transmission include increased menstrual bleeding adherence to IUD's tails of bacteria, viruses, cervical mucus; and fragmentation of copper spirals of copper IUD's. The infectivity rate of seropositive women wearing IUD's is aggrevated further by absorption, by IUD tail, of HIV virions and infected cellular elements in the semen. These adverse responses are protected from publication by certain wealthy pharmaceutical companies. Copper salts and black copper dental cement may induce itching urticarial rash thrombocytopenic purpura, an allergic reaction. In developing countries, most risk groups for AIDS and contraception are similar. AIDS counseling can be conducted in an INTEGRATED Family Planning/Maternal-Child, Health Centers/Drug Treatment Center/STD Clinics.

B.503 ETUDE PROSPECTIVE DE L'INFECTION A VIH CHEZ LES FEMMES ENCEINTES : SUIVI DE 96 PATIENTES, 51 ENFANTS ET 49 FAMILLES

Nicole Cireru-Vigneron, R. Nguyen Tan Lung, C. Brunner, P. Honderlick, J.L. Wautier, J.H. Ravina et al.
Hôpital Lariboisière, Université Paris VII, Paris, FRANCE.

Objectifs : Déterminer la prévalence de l'infection à VIH chez les femmes enceintes, leurs enfants et leurs partenaires, en étudier l'évolution, apprécier le rôle éventuel de la grossesse.
Méthodes : Depuis 1986 nous avons institué le dépistage systématique chez les consultantes, et en cas de positivité, celui des nouveaux nés et des familles, apprécié régulièrement les stades évolutifs, étudié les foetus.
Résultats : Nous avons inclus 96 nouveaux cas (3 patientes enceintes 2 fois) ; 40 grossesses ont été interrompues, 59 poursuivies. Dans les groupes à risque la prévalence est de 5 %, chez les autres 0,5 %. Pendant la grossesse, les stades ont pu être appréciés chez 59 femmes : 42 stades II, 17 stades III. L'évolution de la grossesse et l'accouchement n'a pas posé de problèmes particuliers. Depuis leur grossesse, 41 femmes sont suivies : 23 stades II, 17 stades III. La grossesse n'a pas modifié les stades, aucune patiente n'est décédée. Un seul des 6 foetus étudiés avait des anomalies. Parmi les 56 enfants nés, 34 sont déjà évaluables avec 15 (44 %) infectés : 6 stades P1, 8 stades P2 et un décédé. Dans les 49 familles revues, 19 (38 %) partenaires sont infectés, et sur 35 enfants antérieurement nés, 3 sont séro positifs.
Conclusions : Malgré un recul de 3 ans, il est nécessaire de confirmer ces résultats encore préliminaires par le suivi au long cours de la cohorte.

B.504 HIV INFECTION RATES IN PARTURIENTS WHO RECEIVE NO PRENATAL CARE

Killian, H.*; Risi, George*; James, D.*; Muirhead, L**; Shields, J.**; Marier, R.*
*Department of Infection Control, Charity Hospital, New Orleans, La., U.S.A.; **Louisiana AIDS Prevention and Surveillance Program, New Orleans, La. U.S.A.

Objective. To test the hypothesis that women receiving no prenatal care represent a higher risk group for HIV infection than those who receive regular care at an urban hospital serving primarily indigent patients (Charity Hospital [CH]).
Methods. All women presenting to the obstetrical clinics of CH are offered HIV testing and pre/post test counseling (group I). Between 5-10% of deliveries each month at CH are among women who have not received any prenatal care (group II). Beginning 10/1/88 all such women were offered the test during their hospitalization accompanied by pre/post test counseling. All specimens were screened using EIA, with confirmation by Western Blot (WB).
Results. Ninety-eight percent of women in group I and 100% of women in group II consented to HIV testing.

	#tested 10/1/88-1/13/89	# (+) by WB
Group I	1357	8 (0.59%)
Group II	101	1 (1.0%)

Conclusion. In this area where the overall seroprevalence of HIV in pregnant women is low, being outside the health care system is not reflective of being in a higher risk group.

Care

B.505 MASSAGE FOR TERMINALLY ILL AIDS PATIENTS

Ann Ruebottom
Casey House Hospice Inc., Toronto, Ontario, Canada
Coranna Lee
Casey House Hospice Inc., Toronto, Ontario, Canada
P.J. Dryden
Pain Clinic, Sunnybrook Medical Centre,
Toronto, Ontario, Canada

OBJECTIVE: To describe the pioneering venture of using Registered Massage Therapists (RMTs) in a healthcare institution and to outline the massage techniques and modalities contributing to the care of terminally ill AIDS patients at Casey House.
Methods: The activities within the scope of practice of RMTs in Ontario are described, their clinical effects noted and hypotheses for the mode of action proposed.
Results: Physical results include reduction of pain, swelling, anxiety, insomnia, joint stiffness, muscle spasm, skin pathologies. Psychological results include reduction of the feelings of isolation, improved body image/self-esteem.
Conclusion: Registered Massage Therapists have a valuable role in a health care institution. Massage is a useful adjunct in palliative care of AIDS patients by relieving physical symptoms and suffering as well as enhancing social/emotional well-being through the medium of wholesome and skilled touch.

B.506 EVALUATING THE OUTCOMES OF A LINKAGE SYSTEM DESIGNED TO FACILITATE ACCESS FOR CHRONICALLY HOMELESS PERSONS TO AN OUTPATIENT AIDS PROGRAM

Hagerty, Cornelia A. R.N., M.S.N.; O'Connell,J.J.III, M.D.

Significance. The numbers of known HIV+ residents residing in Boston's shelters has grown from 1, in 1985, to more than 75 in 1988. Chronically homeless constitute 25% of the Aids program patients.
Objective. Our primary effort has been to broaden AIDS-specific health care to our city's chronically homeless population by developing a linkage system between The Boston Health Care For The Homeless Project and the Adult AIDS Clinic at Boston City Hospital.
Method. A physician from the Homeless Project cares for the HIV+ shelter patients in the AIDS Clinic thus, the expertise and the network of support systems from both specialties are integrated into the primary care model for this population.
Outcomes. 1. Client-selected case manager system that most often originates in the shelter system,has been better able to track their clients through the health care system and with this information are more effective in their support and cooperation of prescribed therapies.
2. The shelter residents who receive their care in the AIDS Clinic benefit from the AIDS specialty networks, resources, and on-site liaisons from these systems. 3. Clinic visit compliance for the patients in this system is now greater than 75% in an outpatient department that is about 65%.
Conclusion. This initial effort has obtained the results sought and is now considering these patients for clinical drug trials and opening new avenues of care.

B.507

COMPREHENSIVE OUT-PATIENT CARE OF HIV-INFECTED PATIENTS UTILIZING A PRIMARY CARE MODEL

Anastos, Kathryn; Soloway, B.; Ernst, J.; Bronx-Lebanon Hospital Center, Bronx, New York, USA.

Objective. To meet the total health needs of HIV infected individuals, of all ages and all states of illness, in a community with very high HIV seroprevalance.
Method. The establishment of a comprehensive out-patient health care program for HIV-infected individuals.
Results. A community hospital in the South Bronx has developed a program for the out-patient care of HIV infected patients, provided both by primary-care trained physicians practicing in primary-care centers, and by infectious disease sub-specialists in an Infectious Disease Out-patient Center. All sites adhere to uniform, well defined standards of care, specifically designed to meet the health and medical requirements of HIV infected persons in all stages of infection. These include: initial comprehensive evaluation and on-going management of all acute and chronic medical problems, both HIV-related and other (e.g. DM, HTN); evaluation for anti-retroviral and preventive therapies (e.g. PCP prophylaxis); general and HIV-related health maintenance (e.g. immunization, PPD, pap smear, ophthamologic exam, etc.); patient education. Protocols have been developed in detail to cover these and other areas. Provider continuity, including inpatient care, is maintained in all primary care centers. On-going subspecialty input for all patients is provided by the infectious disease team.

B.508

AIDS AND PHISICAL EDUCATION

Freire, S.V.; Machado, I. Z. .
Centro Corsini. (CCII). Campinas.São Paulo.Brazil.

The human is an integral composition of mind and body represented by pleasure and aestetics, emotions and reason. The boby is the very first human experience moment. The individual senses and lives prior to know,partcipating through the boby of the real life.However the individual are being threted by the AIDS virus contamination which brings together the feeling of an ending bench mark an impossibility of action.He is not anymore owner of his body which is now controlled by another owner called HIV. In the enviroment dominated by the AIDS virus, the body is felt through disgust, depression,guilt,rejection,solitude,tension and death.This conduct the patient to a kind of intense exile, rupturing the life links.The body activity represents,at this point in time,an important link with the life since it may be felt though the activity in a concious way.Specialiãtsaare required to help the AIDS patients in an adequate enviroment Which motivatie for the life.In the same Way the specialists need to be helped by the techiniques.In our particular case we use relaxation and movementation to promote the body awarness.Our real possibility isthe creation of an space for the body expression in a awareness way to restore in the patient what his body represents in the workd.

LONG-TERM FOLLOW-UP OF UNTREATED SEVERE THROMBOCYTOPENIA(STP) IN THREE HIV INFECTED DRUG ADDICTS.C.Tural.B.Clotet.G.Sirera. D.Romeu.A.Casals.J.Tor.M.Foz.Infectious Disease Unit.Hospital de Badalona "Germans Trias i Pujol".Barcelona .Catalonia.Spain.Objective:To report the findings and follow-up observed in three seropositive patients who denied any therapeutic approach during a mean period of 18months (range 27-15). Methods:3 out of 12 HIV seropositive IDAs with severe thrombocytopenia(STP) (platelet count < 9000/mm^3 and rich marrow aspirate)related to HIV infection,refused any kind of treatment but accepted a follow-up control each 4 months. Results:are summarized in table 1

Initial Data				Follow-up		
P	st	p/mm^3	T^4/mm^3	months	p/mm^3	T^4/mm^3
1	III	9000	540	27	9000	855
2	III	3000	468	13	53000	409
3	III	9000	351	15	54000	-

Discussion:There were only minor hemorrhagic diathesis manifested by occasional epistaxis in 2 patients and petechiae in lower extremities in all three. An increase in platelet count (> 50000/mm^3) has been observed in the three patients. It was spontaneous in two of them and possibly related to a non-opportunistic disease in the third.Only one has relapsed to the initial low count.None of the three patients developed AIDS during the follow-up period.Since we have observed a low response ratio to steroids(only 25% responded)and due to the potential immunosupressive side effect of prednisone in HIV+ patients, we argue for enhaced control and expectant attitude, although we propose to assay AZT treatment in all of them according to the recent literature.Nevertheless STP is not an unfavorable prognostic sign in IDAs seropositive for HIV.

B.510

FULLY AUTOMATED SYSTEM FOR THE DETECTION AND REGISTRATION OF HIV-ANTIBODIES IN DONOR BLOOD

Meesink,Henk.*; Koot, A.**; Schram, N.*; Plaisir,A.*; Drewes, A.***

* Red Cross Blood Bank, Amsterdam, ** Proton-Wilten, Etten-Leur,
*** Wellcome Nederland, Weesp, The Netherlands.

Objective. To develop a fully automated system for the detection and registration of anti-HIV in donor blood.
Methods. Anti-HIV tests are done with an ELISA system in microtiter plates (Wellcozyme, Wellcome, UK). The automated system functions as follows: microtiter plates are provided with barcoded labels and positioned in a pipetting robot (Tecan RSP, Switserland). Before the pipetting program for the delivery of serum in the wells starts, the plate's barcode is read by a barcode pen and the barcode of the test tubes is automatically read by the built-in laser scanner of the robot. The position in the plate of each sample is stored in an IBM-PC. After the completion of the tests, the plates are automatically read by a reader (Wellcome diagnostics) and the results are stored on a diskette in the IBM-PC. A special program transfers the test results from the IBM-PC to the HP 3000 minicomputer.
Results. The system now operates under routine conditions and over 100,000 serum samples are tested. No major problems were encountered.

Conclusion. ELISA test systems for anti-HIV detection can be fully automated, which contributes to a safer blood supply by avoiding human errors as well as a reduction of the workload in the bloodbank.

B.511

HEMOPHILIAC POPULATION OF COSTA RICA FROM 1979 to 1989

Taylor, Lizeth*; Montero, C.**; Cordero, R.**; Antua, M.C.**; Roy, A.*; Luftig, R.***; Visona, K.A.*
*Louisiana State University-International Center for Medical Research & Training, (LSU-ICMRT), San Jose, Costa Rica; **Hematological Dept., Hospital Mexico, San Jose, Costa Rica; ***LSU Medical Center, New Orleans, Louisiana.

Objective: To analyze the serological profile in the hemophiliac population in Costa Rica.
Methods: Serum samples stored in the LSU-ICMRT serum bank were tested with anti-HIV ELISA (Abbott HTLV-III), Western Blot (LSU-ICMRT), HIV antigen (vironostika-Organon), IRMA HB_sA_g and anti-HB_s (LSU-ICMRT). Clinical data were obtained from the hospital case files.
Results: Of the 147 hemophiliacs, 80 (54%) were positive for either HB_sA_g or anti-HB_s. 64 (44%) were positive for anti-HIV-1 with the following distribution:

Anti-HIV-1	Hemophilia A	Hemophilia B	Hemophilia C	Von Willebrand
Positive	44	18	0	3
Negative	46	3	2	31
TOTAL	90	21	2	34

Sixteen (36%) of the A hemophiliacs were anti-HIV-1 positive since 1980 or before, while 11 (55%) of the B hemophiliacs were positive since 1986. HIV-1 antigen test was done in 39 of the 64 anti-HIV-1 positive hemophiliacs whose sera were available. The presence of the HIV-1 antigen was evaluated in correlation with seroconversion, development of ARC or AIDS and death of the hemophiliac.
Conclusion: The analysis of HIV-1 seropositivity in Costa Rican hemophiliacs provided some new insights into the origin of this disease in Central America.

B.512

IMMUNE ACTIVATION IN HIV POSITIVE AND NEGATIVE HEMOPHILIACS

Yasuharu Nishida; Y. Oura; T. Koyama
M. Higuchi and E. Kakishita
Department of Internal Medicine, Hyogo College of Medicine, Hyogo, Japan.

Objective. To analyze signs of immune activation observed in hemophiliac patients with and without HIV infection.
Methods. The absolute CD4 number, percent , CD4/CD8 ratio, Ia positive cell percent and Ig (G, A, M) were measured on a cohort of 41 hemophiliac patients (18 seropositive, 23 seronegative) followed for 5 years in Hyogo prefecture.
Results. Increased levels of serum IgG and Ia positive cell percent were observed in both seropositive and seronegative groups. And the level of serum IgG in seropositive group was higher than that in seronegative group with statistical significance (P<0.005). Moreover, the correlations between T4/T8 and IgG (r=-0.646), and between T4/T8 and Ia positive cell percent (r=-0.605) were showed only in seropositive group.
Conclusion. Hemophiliac patients show some signs of immunostimulation. Increasing levels of IgG and Ia positive cell percent appear to be correlated with declining immune status in seropositive group.

B.513

HIV-INFECTION IN HEMOPHILIACS IN ARGENTINA

Muchinik,Guillermo;Pérez Bianco,R;Bouzas,MB;Rickard,E;
Armando,E;de Tezanos Pinto,M.
IIHEMA,Academia Nacional de Medicina,Buenos Aires,Argentina.

Objective. To describe an update of HIV-infection in hemophilia.
Methods. HIV antibodies(ab) were detected through EIA (Abbott) and confirmed by means of IFA and ENVACORE (Abbott).
Results. A total of 467 hemophiliacs has been studied since November,1984.

Hemophilia A (n=407)	Severe	Moderate	Mild	Sev.with Inhibitor	Total
Total (a)	256	61	65	25	407
HIV ab pos.(b)	102	17	10	6	135
% pos.(pos.(b)/total hem.(a))	40%	28%	15%	24%	
% pos.(pos.(b)/total pos.A(407))	76%	13%	7%	4%	

Hemophilia B (n=60)	Severe	Moderate	Mild	Sev.with inhibitor	Total
Total (c)	23	22	13	2	60
HIV ab pos.(d)	12	10	0	1	23
% pos.(pos.(d)/total hem.(c))	53%	43%	0%	4%	
% pos.(pos.(d)/total pos.B(60))	20%	17%	0%	2%	

Conclusion. Since 1984 and up to the present time, there has been a progressive decrease in anti-HIV positiveness, coincident with admission of patients less exposed to antihemophilic concentrates. In spite of this, seropositiveness has continued to be statistically significant in severe hemophilia ($p < 0.005$).

B.514

B.515

FINDINGS OF INDETERMINATE RESULTS TO WB (p17, p24, p55) IN MEXICAN NORMAL DONORS.

Romero M.*; Morales C.* and Dominguez J.*
*Centro Nacional de la Transfusión Sanguinea, México, D.F.

Objetive.
The previous detection (screening) which is done mandatory by law to the blood drawn from normal donors showed the presence of certain bands that made WB results indeterminate such instance took us to search for HIV Ag in order to confirm an earlyseroconvertion or posible cross reaction with another retrovirus like HTLV I
Method.
The determination for HIV Ag to 1544 donor samples were made by the method of Elisa using different available brands. Such results were negative, and only 11 samples were positive by Elisa Dupont. WB testing from Dupont was made to these sample
Results.
WB Testing showed the presence of p17, p24, p55 bands (indeterminate) HIV Ag testing in serum was done as well as Ac Anti HTLV I with negative results as a finding.
Conclusion.
The study of these samples still is not over jet at this point in time we're in the stage of re sampleing again to stablish if any of these donors has seroconverted.

B.516

PLATELETS IN HIV-INFECTION: DECREASE ASSOCIATED WITH IMMUNODEFICIENCY. MYCOBACTERIAE INFECTION AND SALMONELLAE SEPTICEMIA. PSEUDOTHROMBOCYTOPENIA IN HIV-INFECTION.

Matuschke, Alexander *; Heinrich, B.*; Welzl, G.**; Bogner, J.R.*; Püeßl, H.*; Goebel, F.-D.*. * Univers. München, Med. Poliklinik, FRG.
** MEDIS, GSF Neuherberg, FRG.

Objective. To describe different events associated with platelet reduction in HIV-infection.
Methods. Classification of immunodeficiency according to Walter Reed Classification System (WR 1-6). Documentation of the first platelet count / µl (PL) at admission, after progression in WR, after developing an opportunistic infection or malignoma and in HIV-ab. negative risk groups (HIV -). Semiquantitative assessment of megakaryopoiesis in bone marrow cytology (number of megakaryozytes (MEGAK) / low power field).
Results.

	HIV -	WR 1	WR 2	WR 3	WR 4	WR 5	WR 6
Mean PL counts:	255327	242388	229582	209846	219059	181207	211931
std. dev.:	58916	67899	71065	64381	55161	76975	87404
n =	137	49	55	26	17	29	58

PL < 100T were found in 6% (14/234). PL of 100T-150T in 11% (26/234), both predominantly in WR 5 and 6. In 11 of 17 mycobacteriae infections PL < 150T were found. In 1 case of salmonella septicemia a transient PL decrease occurred. One transient EDTA-dependent pseudo-thrombocytopenia (-TP) due to PL-associated antibodies was detected.
Bone marrow cytology in WR 1-5 and PL < 100T (n = 6) showed high numbers of mostly juvenile MEGAK suggestive of immune-TP. In mycobacteriae infections and PL < 100T (n = 4) high numbers of MEGAK were found also, whereas in 5 of 6 other opportunistic infections MEGAK were low.
Conclusion. In HIV-infection immune-TP, TP due to ineffective hematopoiesis and a slight decrease of PL with progressing immunodeficiency seems to occur. In thrombocytopenia an EDTA-dependent pseudo-TP and infections with mycobacteriae and salmonellae must be considered.

B.517

EVALUATION OF HIV-ANTIBODIES IN SAMPLES OF COMMERCIAL PREPARATIONS OF γ-GLOBULIN FOR PARENTERAL USE IN THE PERIODS 1973 1981 AND 1984-1986.

Tinelli M.; Cattaneo E.; Achilli G.
Institute of Infectious Diseases, IRCCS - Policlinico S. Matteo, Pavia, Italy.

Objective. Evaluation of the presence of HIV-antibodies in γ-globulin different commercial preparations in the periods 1973-1971 and 1984-1986.
Methods. Samples have been screened by ELISA commercial kits and, if positive, confirmed by home made western-blot.
Results. In period 1973-1981 we tested 13 γ-globulin lots and all the preparations were negative for HIV-antibodies. In period 1984-1986 we evaluated 25 γ-globulin lots and 22/25 were positive in ELISA, while 25/25 were positive in Western-blot. Western-blot reactivity was mainly directed against p 17 and p 24 "core" proteins and gp 41 "transmembrane" glicoprotein. Reactivity against "core" p 17 and p 24 proteins and not against gp 41 glicoprotein was demonstrated in same preparations.

γ-globulin	No. tested	ELISA pos.	WB pos.
1973-1981	13	0	0
1984-1986	25	22	25

Conclusion. At present, the transmission of HIV-infection by human γ - globulin preparations has not been yet demonstrated. The potential presence in the human immunoglobulin for parenteral use of anti-HIV antibodies suggest the routine-screening of blood donors to obtain a safe product.

B.518

CORRELATION OF THE HIV AND HTLVI ANTIBODY, HIV ANTIGEN IN HAEMATOLOGICAL DISEASE (H.D.).

L. Granati•, F. Mandelli, G.Isacchi•, G. De Rossi•, M. Titti", M. Pezzella'et al. .
•Haematological Section-Human Biopathology Departments. 'Infectious disease Chair. University of Rome. "Istituto Superiore di Sanità. Roma.

Objective: to investigate the prevalence, the correlation and the follow up of HIV antibody, HIV antigen, HTLVI antibody in H.D., to investigate the significance of indeterminate western blot.
Methods: During 1988, 1400 patients with H.D. were tested by ELISA (Organon) for HIV antibody (if positive W.B. was performed), in 5 of these with indeterminate W.B., the in situ ibridization, using D.N.A. probes, visualized by sandiwich immunoistochemical reaction (alcaline phosphatase) was performed. 600 out of 1400 patients were studied for HIV antigen and 1000 for HTLVI antibody.
Results: As for HIV antibody among 1400 patients: 1295 resulted negative (92.5%) 101 positive (7.5%): 50 diagnosed before 1988-already positive-, 50 in 1988-new positive-. 5 cases showed P24,P55 at W.B. but only one infected mononuclear cells. Among 176 haemophilic patients 30 (17%) were already positive and 15 (8.5%) recently diagnosed. Among 261 patients with limphoadenopathy, thrombocytopenia and miscellaneous 21 (8%), 29 (11%) 211 (81%) were respectively already positive, new positive and negative. 5 out 963 (0.5%)of other cases were positive. 2 out 600 were positive for HIV antigen and 3 out 1000 for HTLVI antibody. Conclusion: limphoadenopathies, thrombocytopenias and haemophilia showed the higher prevalence for HIV antibody.

B.519

EXTRAPULMONARY CRYPTOCOCCAL DISEASE AS A MANIFESTATION OF AIDS IN LOUISIANA

Atkinson, William*,**; Troxler, S.*; McFarland, L.*
*Louisiana Department of Health and Hospitals, New Orleans, LA, USA;
**Tulane University School of Public Health, New Orleans, LA, USA.

Objective. To determine the frequency and characteristics of patients with extrapulmonary cryptococcosis (EC) as a manifestation of AIDS in Louisiana (LA) residents between 1981 and December 1988.
Methods. Cases of AIDS were identified by an active hospital-based surveillance system. Only definitively diagnosed cases meeting the CDC case definition were included in the analysis. Case data was collected by hospital record review. EC was defined as culture proven cryptococcal meningitis or sepsis.
Results. As of 12/30/88, 957 cases of AIDS were identified in LA residents (943 adult and 14 pediatric). One hundred ten (11.5%) cases were diagnosed with EC, 109 in adults and one child. For 76 (69%) patients EC was the only opportunistic infection identified. Patients with EC did not differ significantly from AIDS patients without EC by age, sex or risk group. Forty-eight percent of EC in adults with AIDS were black. Of 276 black adults with AIDS, 53 (20.3%) had EC compared to 53/667 (7.9%) of white adults with AIDS. The proportion of AIDS cases with EC does not appear to be increasing over time.
Conclusion. EC is a frequent manifestation of AIDS in Louisiana (11.5%), more frequent than for the U.S. as a whole (7.7%). Black patients with AIDS appear to be at higher risk of EC than whites.

B.520

INFECTION PAR HIV 1 AU DECOURS D'UNE GREFFE DE FOIE : ETUDE DE 2 MALADES PENDANT 2 ANS.

Vanhems, Philippe; Bresson-Hadni, S.; Vuitton, D.; Lab, M.; Miguet, JP. et l'Unité de Transplantation Hépatique.
Centre Hospitalier et Universitaire, 25030 BESANCON, France

Objectif. Analyser l'évolution clinique et sérologique d'une infection par HIV survenue au décours d'une greffe de foie (GF).
Méthodes. Une surveillance clinique et sérologique a été réalisée chez 2 malades (m1 et m2), séronégatifs pour HIV avant GF, pendant 2 ans après une GF indiquée chez m1 pour une cirrhose virale B et chez m2 pour un cholangiocarcinome. L'infection par HIV était liée à une toxicomanie reprise dans le mois précédant la GF pour m1, et à la greffe d'un foie HIV+ par erreur de transmission des résultats sérologiques chez m2.
Résultats. L'Ag p24 était décelable de J25 à J36 chez m1, et dès J20 jusqu'en fin d'évolution chez m2. Les Ac anti p18, p24, p55, p64, gp41 et gp60 ont persisté à un taux élevé à partir de J132 chez m1. Les Ac anti p24, p31, gp41 transmis passivement ont disparu à J48 pour réapparaître et persister à partir de J254. L'évolution (sous traitement par ciclosporine) a été marquée par une mycose buccale à J90 chez m1, des adénopathies chez m2, et la récidive de la pathologie initiale chez m1 et m2 entraînant le décès de m2, 2 ans après la GF. Les lymphocytes CD4+ étaient <200/µl dès J159 chez m1, et toujours >500/µl chez m2.
Conclusion. Contrairement aux observations antérieurement rapportées, ces infections par HIV contemporaines d'une GF n'ont pas été marquées par une évolution particulièrement défavorable.

B.521

IS ENTAMOEBA HISTOLYTICA IN HOMOSEXUAL MEN A PATHOGEN?

Weinke,Thomas*; Friedrich-Jänicke,B.**; Janitschke,K.***
* Universitätsklinikum Rudolf Virchow, Freie Universität Berlin, West-Germany.
** Landesinstitut für Tropenmedizin, West-Germany.
*** Robert Koch-Institut Berlin, West-Germany.

Objective. Entamoeba histolytica occurs frequently among sexually active homosexual men. We tried to evaluate the clinical importance of this protozoa.
Methods. 320 male homosexuals were screened for intestinal parasites. E. histolytica was cultured in Robinson' medium and positive cultures were classified into zymodemes by means of starch-gel electrophoresis. Serological tests for E. histolytica were done in two different methods (IFAT and Elisa). Each individual was asked for clinical symptoms.
Results. 52 out of 320 (16,3 %) male homosexuals presented with E. histolytica in their feces. An isoenzyme classification was achieved in 26 patients and all belonged to non-pathogenic zymodemes. This correlated well to negative amebic serology in all subjects. 13 patients presented with diarrhea. In 5 of these 13 diarrhea could be explained by other enteric pathogens; in 8 patients no other pathogen was detected. In HIV-infected persons with inquired immunity no signs of invasive amebiasis were seen.
Conclusion. In male homosexuals only non-pathogenic zymodems of E. histolytica were found. Also in long lasting infections these zymodemes remain stable. We found no hint for invasive amebiasis in these patients. E. histolytica strains with a non-pathogenic zymodeme seem to be harmless commensals.

B.522

SPONTANEOUS BACTERIAL PERITONITIS AND AIDS

Biancalana, Maria Lucia, Mendes, W.S.; Levi, G.C.; Carvalho, M.C.S.; Mendonça, J.S.; Trevisanello, C. Serviço de Molétias Infecciosas, Hospital do Servidor Publico Estadual - São Paulo, Brazil.

The authors relate a case of a 28-year-old white homossexual man with AIDS, who was being treated for Kaposi's sarcuma and toxoplasmic encephalitis during 7 months when he developed aqueous diarrhea, weakness an difuse abdominal pain. The physical examination revealed poor general condition, anemia, dehydration, anasarca, disseminated cutaneous Kaposi's sarcoma and a distended and painful abdome. Laboratory results were as it follows: leukocytes counts 11.000 with 94 per cent of polymorphonuclear cells; CD4 < 200; CD4/CD8 0,5 seric albumin 2,4 gammaglobulin 1,3; protrombin time 67 per cent (15,5 seconds), and normal hepatic biochemistry values. Five days after admission ascites developed. Abdominal paracentesis was performed and a cloudy liquid was observed. Spontaneous bacterial peritonitis was suspected and empiric treatment with Cephalotin (8g/day) was initiated. Peritoneal liquid analysis revealed: leucocytes counts 7000, with 100 per cent of polymorphonuclear cells, peritoneal liquid protein 0,5 and peritoneal liquid DHL/seric DHL 0,8. Bacteriological studies revealed the growth of C.group Salmonella with susceptibility to various antibiotics, including Cephalotin. In spite of 5 days of antibiotic therapy unfavourable evolution was observed and he died in the ninth day of hospitalization. As we have no knowledge of reports of spontaneous bacterial peritonitis in HIV patients, we think this case description may be helpful in enlarging our knowledge about clinical manifestations of this disease.

B.523

CHOLECYSTITE ALITHIASIQUE, STENOSE DE LA PAPILLE, CHOLANGITE SCLEROSANTE ET SIDA.

P. Weinbreck ; V. Loustaud ; D. Valleix ; M. Mounier ; F. Denis
Unité des Maladies Infectieuses - CHU LIMOGES - 87042 FRANCE

L'atteinte des voies biliaires est une complication rarement décrite du SIDA.
Objectif : Décrire un cas de l'association cholécystite alithiasique, sténose de la papille et cholangite sclérosante comme complication d'une Cryptosporidiose au cours d'un SIDA.
Cas clinique : Un homosexuel de 34 ans, HIV 1 positif et ayant un passé de plus de 5 mois de diarrhée sévère à Cryptosporidie, est hospitalisé pour un tableau clinique de cholécystite aigue. Il existe une cholestase biologique (Cf tableau). L'échographie hépato-biliaire met en évidence un aspect de cholécystite alithiasique à parois épaissies (10 mm), une dilatation des voies biliaires intra-hépatiques et une voie biliaire principale dilatée à 14 mm (photo). L'exploration chirurgicale confirme la cholécystite alithiasique. La cholangiograhie per-opératoire retrouve d'une part une importante dilatation de la voie biliaire principale avec un aspect d'oddite du bas cholédoque (photo), d'autre part un aspect très évocateur de cholangite sclérosante au niveau des branches de division secondaire des voies biliaires intra-hépatiques (photo). Aucun agent pathogène n'est isolé en dehors des Cryptosporidies dans la vésicule et la bile ; les cultures virales sont négatives ; aucune inclusion cytomégalique n'est retrouvée. Une sphinctérotomie endoscopique s'avère nécessaire devant la récidive de la dilatation après clampage du drain chirurgical.
Discussion : Les aspects cliniques et étiologiques de ces anomalies acquises des voies biliaires au cours du SIDA sont discutées.
Conclusion : Tout SIDA présentant une augmentation durable des phosphatases alcalines devrait bénéficier d'une échographie hépato-biliaire.

B.524

SPONTANEOUS RUPTURE OF SPLEEN IN A H.I.V. SEROPOSITIVE NON THROMBOCYTOPENIC PATIENT.

Pesce,Alain; Vinti,H.; Taillan,B.; Fuzibet,J.G.; Dujardin,P.; Cassuto,J.P.
Services de Médecine Interne I et II - Hôpital de Cimiez - CHRU Nice, France.

We recently observed a case of rupture of the spleen, in a HIV seropositive asymptomatic and non thrombocytopenic patient in relation with a large spontaneous splenic hematoma. A 25-old male patient, intravenous drug abuser from 1982 to 1984, HIV seropositive since February 1986 and regularly followed without any symptoms, presents with abdominal pain and deglobulization. There was no abdominal traumatism. Echography and CT. scan showed mild splenomegaly with heterogeneous zones, and intraperitoneal blood. There was not any alteration of hemostasis. Platelets were 218 x 10.9/1. Patient did not take any drugs or toxic, and there were no signs of opportunistic infection.
Splenectomy was performed : spleen was large, 460 g weight, with rupture on inferior pole and a 4 cm circonference hematoma. On microscopy there was a follicular hyperplasia commonly observed in HIV seropositive patients. The research of disease responsible of spleen rupture was negative. Actually, patient remains well and his HIV status is always asymptomatic. Spontaneous rupture of the spleen has been described in a lot of affections, frequently of viral origin. In our patient the research of any cause of spleen rupture is negative, and not any alteration of hemostasis, frequently observed in HIV positive patients such as thrombocytopenia and/or circulant anticoagulant was found. However, generalized lymphadenopathy and splenomegaly are well known in HIV seropositive patient, and this chronic viral portage may be responsible of spleen damage followed in rare cases by spleen rupture.

B.525

THE PREVALENCE OF THE HEPATITE B VIRUS (HBV) MARKERS IN PATIENTS CARRIERS OF ANTI-HIV IN SAO PAULO, BRAZIL. Diaz,R.S.; Silva,A.E.; Ferraz,M.L.; Sador,M.S.; Castilho,M.P.; Lewi,D.S. from Escola Paulista de Medicina, Sao Paulo,Brazil.

Objective:To study the behaviour of VHB infection in patients who are carriers of HIV, separated in two distinct groups evaluated in different times. The two groups were compared betwen themselves and with a control group of blood donors from a blood bank.

Material and Methods:The pacients were divided in two groups depending on the time they were evaluated.

Group 1-29 patientes anti-HIV positive(Elisa,Lab. Abbott) homo or bissexual studied from 1982 to 1983,where were determined the HBV markers(Elisa,Lab.Abbott): HBsAg, antiHBc and antiHBs.

Group 2-43 patients anti-HIV positive(Elisa,Lab.Abbott) homo or bissexual studied from 1987 to 1988, where the markers from HBV described above were determined.

Control Group-Blood donors from a blood bank in the city of Sao Paulo.

Our statistical analisis was made using the Qui-square and Fisher's exact test and were considered significant when differences were p<0,05.The results are presented bellow:

	CONTROL	GROUP-1		CONTROL	GROUP-2		GROUP-1	GROUP-2	
HBsAg	5/500	03/29	p<0.001	5/500	08/43	p<0.000001	3/29	9/43	p<0.3
	1.0%	10.3%	OR=11.4	1.0%	23.2%	OR=26.2	10.3%	23.2%	
AntiHC	15/100	28/29	p<0.000001	15/100	33/43	p<0.03	28/29	33/43	p<0.03
	15.0%	96.5%	O=159	15.0%	67.4%	OR=8	96.5%	67.4%	OR=8
AntiHS	24/97	24/29	p<0.000001	24/97	15/43	p<0,001	24/29	19/43	p<0.001
	24.7%	82.7%	OR=14.6	24.7%	37.2%	OR=6	82.7%	37.2%	OR=6

Results:The results can sugest that in initial HIV infection period in our communit (1982-1983) there was a tendency to better imunological response to the HBV, shown by the greater incidence of anti-HBS in the HIV positive patients studied from 1982 to 1983 when compared to the group of HIV positive patients studied from 1987 to 1988.

B.526

SEROPREVALENCE AND CLINICAL CORRELATES OF HERPES SIMPLEX VIRUS (HSV) ANTIBODY IN 41 AIDS PATIENTS.

Sharon Safrin*, C. Houlihan*, A. Arvin**, J. Mills*
*San Francisco General Hospital, (University of California) and **Stanford University Medical Center.

Objective: (1) To assess the clinical course of mucocutaneous HSV in patients with AIDS; (2) To determine the seroprevalence of HSV antibody in this cohort; (3) To analyze the correlation of the presence of serum HSV antibody with clinical herpetic disease activity.
Methods: Forty-one patients with the diagnosis of first-episode *Pneumocystis carinii* pneumonia in 1986 were studied. Data regarding history of clinical outbreaks of herpetic infection, viral typing of isolates, and therapy with acyclovir (ACV) was collected retrospectively by review of the medical chart. Specimens for viral culture were inoculated onto human diploid fibroblast monolayers: virus typing was performed using fluorescein labelled monoclonal antibodies to HSV-1 and HSV-2. Serologic assay was performed for antibody to the HSV glycoprotein gG-2.
Results: Of 33 patients in whom clinical data was available, 24 had recorded outbreaks of mucocutaneous HSV infection. Locations of herpetic outbreaks included the perirectal (N=14), orofacial (N=10), and genital (N=4) areas. Virus typing demonstrated HSV-1 in 3 patients and HSV-2 in 9 patients. Seventeen of 24 patients received therapy with oral ACV for HSV infection; one patient was treated with intravenous ACV. Six patients received chronic suppressive therapy with ACV, for intervals ranging from 2 to 16 months. Data on antibody titers to HSV-1 and HSV-2 in these 41 patients will be presented.
Conclusion: Clinical HSV infection in common in patients with AIDS; location and virus type is variable. Correlation of serologic HSV status with clinical herpetic activity will be reported.

B.527

DISEASES OTHER THAN AIDS AMONG IV DRUG USERS.
E.J. Trapido*, C.B. McCoy*, D.D. Chitwood*, H.V. McCoy**, and J.A. Inciardi***, *University of Miami Medical School, Miami, FL, USA; **Florida International University, Miami, FL, USA; ***University of Delaware, Newark, DE, USA.

Objective: To describe the distribution of disease other than AIDS among a cohort of IV drug users.
Methods: As part of a study which tests two interventions to reduce the risk of AIDS among IVDUs, 346 subjects were recruited from drug networks, tested for HIV-1 positivity, and interviewed. Bivariate analyses were performed to assess associations between variables, and relative risks (and 95% confidence intervals) were calculated.
Results: Genital sores were reported among 11.3% of the cohort; pneumonia among 18%; hepatitis among 10%; tuberculosis among 6%; gonorrhea among 39%; syphilis among 19%, and genital herpes among 3.5%. Rates varied by race/ethnicity, with whites and Hispanics having twice the reported frequency of hepatitis and herpes of blacks, and tuberculosis seen only in blacks and Hispanics. HIV-1 seropositives were more than twice as likely to report a history of syphilis than seronegatives (1.4-3.4).
Conclusion: A variety of non-AIDS diseases occur in IV drug using populations which may present opportunities for targeted screening and interventions.

B.528

B.529

INCREASED INCIDENCE OF M. KANSASII INFECTION DUE TO AIDS AND HIV INFECTION AT COOK COUNTY HOSPITAL, CHICAGO
* Renslow Sherer, M.D.; ** Kocka F., * Muthuswamy P., * Pulvirenti, J.
* Blair S.; * Sonnenberg, M. et. al.
* Department of Medicine, ** Department of Laboratories, Cook County Hospital

Objective: To compare the incidence of M. kansasii infection at Cook County Hospital (CCH) from 1977-1982 and 1983-1988, and to evaluate the significance of associated AIDS and HIV infection.
Methods: All patients with M. kansasii infection between 1977 and 11/88 were cross-referenced with all persons with AIDS and HIV infection (AIDS/HIV), and a retrospective chart review was conducted to determine the site of infection and HIV status.
Results: Table I shows the results:

TABLE I

	All M. kansasii	Dissem. M. kansasii	AIDS	HIV+
1977-1982	23	0	0	0
1983-1988	40	6	10	5

An increase of 17 cases (57%) was observed from 1977-1988; of these, 15 (88%) were persons with AIDS/HIV infection. From 1983-1988, 15 (37.5%) of infections occurred in the AIDS/HIV group. Of these, 10 had AIDS, and 5 symptomatic HIV infection (Class IV). Of 6 patients with disseminated disease between 1983-1988, all had AIDS.
Conclusions: A 57% increase in M. kansasii infection at Cook County Hospital from 1977 to 1988 was primarily due to associated AIDS and HIV infection. Disseminated infection occurred only in persons with AIDS. HIV counseling and testing of patients with M. kansasii infection, and diagnostic and therapeutic interventions for M. kansasii infection in AIDS in endemic areas are appropriate.

B.530

THE KOËBNER PHENOMENON IN AIDS-RELATED KAPOSI'S SARCOMA
Janier Michel*, Baccard M.*, Cabotin PP.*, Timsit F.*, Colonna A.* and Morel P.*
* Centre Clinique et Biologique des MST, Hôpital Saint-Louis, Paris, France.

The Koëbner phenomenon is the development of isomorphic lesions in the traumatized normal skin of patients who have psoriasis, lichen planus or various cutaneous diseases. Kaposi's sarcoma (KS) in its classical form sometimes koëbnerizes. We have observed 4 cases of Koëbner phenomenon in the course of AIDS-related KS.
Case 1 : Homosexual male, 46, with cerebral toxoplasmosis. A single lesion of KS developed at the site of a prior venous puncture.
Case 2 : Homosexual male, 40, LAS ; A KS lesion developed at the site of a BCG abscess. Other lesions of KS appeared thereafter.
Case 3 : Homosexual male, 38. A KS lesion developed after hurting himself with a dumb bell for body building. Other lesions appeared thereafter.
Case 4 : Homosexual male, 36. A KS lesion developed on the right flank after strongly bumping himself against a table. Other lesions appeared thereafter.

AIDS-related KS could potentially arise in every patient infected with the HIV but nevertheless only occurs in a minority of them, mainly homosexuals. Secretion of soluble angiogenic factors by HIV infected lymphocytes might explain the endothelial proliferation but additional factors are necessary. Among these factors wich remain controversial (genetic predisposition, poppers, other virus infection), trauma is another trigger mechanism.

B.531

ANO-RECTAL SURGERY OF AIDS PATIENTS.

Fraga, L.F.P.*; Bravo, F.P.*; Paulo, F.L.*; Quinhões, Eleonora Pati**; Rachid, de Lacerda, M.C.**

**Gaffrée & Guinle University Hospital - University of Rio de Janeiro - Brazil.
* Pedro Ernesto University Hospital, State University of Rio de Janeiro (UERJ) - Brazil.

Objective: To discuss the importance of proctologic surgical procedures for HIV infected patients.

Methods: During 1987 and 1988 we operated 20 HIV infected patients of groups II, III and IV of CDC criteria. All patients were tested for HIV antibodies by ELISA, Indirect Immunefluorescence and/or Western blot.

Results: Patients were all males, 18 homo/bisexuals (90%), 1 blood transfused (5%) and 1 intravenous drug abuser (5%). The ano-rectal diseases studied were: 10 fistules, 5 fissures, 3 biopsies of perianal lesions, 1 hemorroid, and 1 criptitis. Only 2 cases had delayed resolution after surgery - one from group II and one from group IV.

Conclusions: We conclude that under a criterious selection, HIV infected patients should be treated for co-existent ano-rectal diseases. Positive results justify the importance of proctologic surgical procedures for these patients that are already suffering deeply because of HIV infection.

RADIOGRAPHIC PATTERNS OF PULMONARY TUBERCULOSIS AMONG AIDS PATIENTS IN RIO DE JANEIRO - BRAZIL.

Eyer-Silva, W.; Graça, M.H.P.; Camera, C.S.; Teixeira, E.; Sion, F.S.; Morais de Sá, Carlos Alberto.

Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: Describe roentgenographic features of pulmonary tuberculosis among Brazilian AIDS patients.

Methods: We reviewed standard chest radiographs of 42 patients who met the current CDC criteria for AIDS and who also had a diagnosis of pulmonary tuberculosis.

Results: Among 42 patients reviewed, 41 were men and 1 was woman, with mean age 34,4 ± 9,0. Twenty-four (57,1%) also had extrapulmonary disease. Chest radiographs revealed diffuse interstitial infiltrates in 6 (14, 3%), hilar and (or) mediastinal lymphadenopathy in 7 (16,6%), pleural effusion in 13 (31,0%), miliary infiltrates in 9 (21,4%), localized pulmonary infiltrates involving middle or lower lung field in 14 (33,3%), localized pulmonary infiltrates involving upper lung lobes in 11 (26,2%), cavitation in 4 (9,5%), pericardial effusion in 3 (7,1%) and normal chest radiograph in 6 (14,3%). Only 3 patients presented with localized upper pulmonary infiltrates without lymphadenopathy, a typical pattern of reactivation tuberculosis, frequently seen in non-immunossupressed patients.

Conclusion: Although we strongly believe that most, if not all, patients had disease due to reactivation of latent bacilli, radiographic pattern was highly atypical for secondary tuberculosis.

B.533

ECHOCARDIOGRAPHIC (ECHO) FINDINGS IN HIV INFECTED PATIENTS.

Talberg, J.; Morais de Sá, Carlos Alberto; Cantisano, A.L.; Oliveira, D. P.; Sion, F.S.; Rubini, N.P.M.

Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To study echocardiographic findings in patients infected by HIV, groups III and IV (C.D.C.), from the out-patients unit and from in-patients of the HUGG, related to the period from August'85 to November'88.

Methods: Parameters of dimensions, structures movements and cardiac functions were obtained by ECHO in 60 patients. The findings were classified individually and in cardiac segments (pericardium, myocardium and endocardium).

Results: Group III: 19 cases, all males,aged from 18 to 34 ($\bar{m}$ = 28,7). Risk groups: homosexuals - 10 (52,6%), haemophiliacs - 1(5,3%), drug-addicts - 1(5,3%) and 7(36,8%) unknown. Normal ECHO found in 11(57,9%), mitral valve prolapse - 3, isolated increased dimensions - 5, left ventr. hypocontratility - 1 and tachycardia 2 cases. Group IV: 41 cases, 38 males and 3 females. Aged from 14 to 54 (m = 34,3). Risk groups: Homosexuals - 28(68,3%), haemophiliacs - 2(4,9%), drug-addicts - 3(7,3%), blood transfusion - 1(2,4%); heteroxesual transmission - 1(2,4%) and 6 (14,6%) unknown. Two ECHOS were inconclusive. From the remaining 39, 15 were normal (38,5%). Isolated pericardial disease in 8 cases (20,5%), dilated cardiomyopathy in 1 (2,6%) and endocardial disease in 2(5,1%). Association of myocardial and pericardial disease in 6 cases (15,4%) and non-specific alterations in 7 (17,9%), pericardial effusion was the most frequent individual finding - 14 cases (35,9%).

Conclusion: Group III presented 1 patient with findings of mild cardiomyopathy. The others were normal or with non-specific alterations. Group IV presented 61,5% patients with ECHO alterations, the most frequent being pericardial effusion. The 2 cases with endocarditis were drug-addicts.

B.534

CARDIOLOGIC FINDINGS IN AUTOPSIES OF AIDS PATIENTS.

Talberg, J.; Morais de Sá, Carlos Alberto; Oliveira, C.A.B.; Signorine, D.J.H.P.; Graça, M.H.P.; Ismael, C.

Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To study the cardiologic findings in autopsies of AIDS patients performed at the Department of Pathology, Gaffrée & Guinle University Hospital.

Methods: We studied the cardiologic findings in the autopsies of 33 AIDS patients classified individually and per cardiac segment (pericardium, myocardium and endocardium) related to the period from March'85 to November'86.

Results: Sex: 31 males, 2 females. Risk groups haemophilia - 16(48,5%), homosexualism/bi 14 (42,4%), blood transfusion - 1(3,0%), unknown - 2(6,1%). Isolated pericardial disease were found in 9 cases (27,3%), isolated myocardial disease in 2(6,1%) and endocardial disease in 3(9,1%). Association of myocardial and pericardial disease in 7(21,2%), pericardial and endocardial disease in 4(12,1%) and the 3 segments in 1 case (3,0%). The most frequent individual finding was pericarditis - 19 cases (57,6%) followed by pericardial effusion in 9 cases (27,3%). One case of Chagas'Disease and 6 with no cardiac alterations. Five from these 6 cases belonged to the haemophiliac group.

Etiology: Endocarditis due to T.B. - 1 case (3,0%), Torulosis - 2 cases (6,1%), Candidiasis - 1 (3,0%). It was not possible to determine the etiology of the remaining findings.

Conclusion: Most of autopsies perfomed (78,7%) evidenced cardiac alterations almost equally distributed between isolated (42,4%) and associated lesions (36,4%). The most frequent findings were related to pericardium (60,6%).

Etiology was not asserted in most of the cases. The majority of the normal heart (83,3%) belonged to the haemophiliac patients.

B.535

INTERET DES PEPTIDES SYNTHETIQUES SPECIFIQUES VIH1-VIH2 POUR DES SERUMS PROVENANT D'ABIDJAN

Guéguen, Monique*; Abissey, S.***; Ruffault, A.**; Guisth'Au, O.**; Yao, T.*** et Genetet, B.*.

*CRTS;**Lab. Vir. CHU,Rennes,France;***Lab. Imm. Hém. CHU, Abidjan,Côte d'Ivoire

Objectif. Confirmer une première sérologie VIH1 et/ou 2 chez 110 patients prélevés entre Mai 1988 et Août 1988 au CHU d'Abidjan.

Méthodes. Dépistage ELISA en ELAVIA 1 et 2 (Diagnostics Pasteur). Confirmation en W.B. par "New" LAV Blot 1 et 2 (D.P.): les critères de l'OMS ont été retenus pour l'interprétation; puis par pepti-LAV 1 et 2: nouvelle méthode utilisant 2 pept. synth. spéc. mimant 1 épitope de GP 41 et 1 de GP 36.

Résultats. Sur 352 sérums testés, 110 étaient positifs en ELAVIA 1 et/ou 2.

Spécificité	ELAVIA	Western-Blot	Pepti-LAV 1 et 2
VIH1+ seul	5	54	67
VIH2+ seul	0	1	6
VIH1+ et VIH2+	105	50	30
VIH1- et VIH2-	/	5	7

5 sérums sur 110 n'ont pas été confirmés en W.B. et 7 en pepti-LAV. Les 2 sérums discordants ont un profil de séroconversion. On constate une proportion élevée de double spécificité: 47.6% si on se réfère au W.B., et 28.6% si on se réfère au pepti-LAV, double spécificité qui se retrouve en majorité chez les patients symptomatiques: 27/30 (90%).

Conclusion. En raison des fortes réactions croisées entre les 2 virus et de l'interprétation difficile des W.B. des sérums africains, un test spécifique est indispensable mais devrait être aussi sensible que le Western-Blot.

B.536

EVALUATION OF A RAPID MEMBRANE BASED ASSAY (HIV CHEK) FOR DETECTION OF ANTIBODY TO HIV IN SERUM SAMPLES FROM NAIROBI

Moss, Gregory B*,***, Maitha G.*, Plummer FA.*,**, Wamola IA.*, Ndinya-Achola JO*, Kreiss JK.***.

*Univ. Nairobi, Kenya; **Univ. Manitoba, Winnipeg, Canada; ***Univ. Washington, Seattle, USA.

OBJECTIVE: To evaluate a rapid membrane based HIV antibody assay.

METHODS: Serum obtained from various Nairobi clinics where HIV studies are being performed were tested for HIV antibody by ELISA and a rapid membrane based assay (RA) (HIV CHEK, Dupont). Western blots (WB) were performed on samples positive on either assay and on a subset of negative samples. A sample was considered HIV+ if it was WB+, and negative if it was either WB- or ELISA- if no WB was performed.

RESULTS: 567 serum samples were obtained. Of 562 producing interpretable RA results, 197(35%) were positive (RA+) and 365 (65%) were negative (RA-). WB was performed on 192 RA+ and 93 RA- samples. Compared to WB, the RA had a sensitivity of 93.6% and specificity of 96.4%. Compared to a WB/ELISA determined HIV status, the RA had a sensitivity of 93.6% and specificity of 99.4%. 14 of 369 (3.8%) frozen specimens had to be centrifuged to obtain an interpretable RA result.

CONCLUSION: This RA compares well to WB. It may be of particular utility where standard laboratory methods are impractical, when a result is needed quickly, or when analyzing single or small batches of samples.

B.537 SERUM LDH ISOENZYME ACTIVITY IN HIV PATIENTS WITH RESPIRATORY DISEASE

Young, Mary* McPherson, R.** Podlasek, S.** Pierce, P.* Georgetown University Hospital, Washington DC. (*Infectious Diseases, **Laboratory Medicine) U.S.A.

OBJECTIVE: To characterize the serum LDH isoenzyme pattern in HIV patients with elevated LDH and bronchoscopically diagnosed PCP or non-PCP respiratory pathogens.
METHODS: 14 HIV pts presenting with fever, cough, SOB or roentenographic findings had serum LDH activity and isoenzyme analysis within 24 hours of bronchoscopy. 2 outpatients with elevated LDH activity but no respiratory complaints were evaluated for isoenzyme analysis (Group C). To assess a standard hospitalized population, 42 non-HIV patients were chosen at random over a 24 hour period for LDH activity and isoenzyme pattern (Group D).
RESULTS: 10/14 HIV/AIDS pts were diagnosed with PCP by bronchoscopy (Group A). In the 4 remaining pts (Group B) no PCP was isolated.

Group	Total LDH (mean)	% LDH (mean) / Absolute LDH (mean) Iso 1	Iso 2	Iso 3	Iso 4	Iso 5
Lab normal	90-180	19-25	25-35	10-20	5-10	0-10
A n=10	478	23/118	36/170	22/103	10/46	9/42
B n= 4	396	17/62	34/122	23/89	11/50	16/72
C n= 2	283	29/81	44/126	16/46	5/15	6/16
D n=42	255	26/62	40/96	18/46	7/18	9/24

CONCLUSIONS: Preliminary data suggest: 1) as per previous studies, elevated serum LDH activity correlates with episodes of PCP although background elevation does occur in hospitalized patients and in non-PCP respiratory disease. 2) In PCP, increases in isoenzymes 2 and 3 are noted. In non-PCP respiratory illness isoenzymes 3, 4, 5 are elevated. Further study is needed to confirm if isoenzyme patterns, in particular isoenzyme 2 and 3, are more predictive of PCP than total LDH in the HIV population.

B.538 MONITORING FOR HIV-1, HIV-2, HTLV-I SERO-PROGRESSION AND SERO-CONVERSION

Constantine, Niel*; Fox. E.*; Rodier, G.**; Abbatte, E.***
*US Naval Medical Research Unit No. 3 (A WHO Collaborating Center for AIDS), Cairo, Egypt, **Cabinet Privé de Médecine Générale, Djibouti, République de Djibouti, ***Direction Technique de la Santé, Djibouti, République de Djibouti.

Objective. To serologically monitor individuals whose sera had previously exhibited reactivity by at least one of seven retroviral screening assays, for sero-progression and sero-conversion for HIV-1, HIV-2, and HTLV-I.
Methods. Sera from 33 high risk individuals in Djibouti were collected and re-examined after four months by western blot (WB) assays for HIV-1, HIV-2, and HTLV-I (DuPont). Resultant WB profiles were compared to those obtained from the same person four months prior. All sera were also tested for antigen by ELISA neutralization (Abbott). An IFA (ENI.) was used to test sera yielding indeterminant results.
Results. Nine sera showed no sero-progression by any WB; one serum exhibited full sero-conversion for HIV-1; one HIV-1 positive (pos.) also became pos. for HIV-2; and two sero-progressed to become HTLV-I confirmed pos. Fourteen samples were WB indeterminant but profiles had progressed to include reactivity to at least one additional virus specific antigen. Six of these had highly suspect profiles, including one IFA pos. serum from a patient who subsequently acquired TB. All sera were antigen neg. The serum which sero-converted by WB had been identified only by the Serodia HIV screening assay.
Conclusion. After four months, some sera had converted from screening assay pos. only, to become confirmed for HIV-1, HIV-2, and/or HTLV-I. Many exhibited progressive profiles. (Supported by NAVMEDRSCHDEVCOM, Bethesda, Md Work Unit No. 3M463105.H29.AA.335.)

B.539 EPIblot-HIV WESTERN BLOT AS SUPPLEMENTAL ASSAY IN TESTING HIV INFECTION

Kaltwasser, Gustavo*, Streeter, M *, Quero, S **; Montiel, F *

*Catholic University of Chile, Faculty of Medicine, Laboratory of Clinical Microbiology-CEDIUC, CH.LE
**Organon-Teknika, CHILE

We evaluated the EPIblot-HIV western blot from Epitope Inc Beaverton, Oregon USA as supplemental test for serum samples from patients suspicious of HIV infection.
This western blot test was used in a total of serum 70 samples: 65 were from patients whose EIA screening tests gave repeatedly positive results, 5 samples from people without any known risk factor for HIV infection were included as extra negative controls. Procedure was performed according manufacturer's instructions. The manufacturer's positivity criteria was the presence of at least two of these bands : gp 160/120, gp 41, p 24. Negativity criteria was the absence of any band. Indeterminate criteria is the presence of any other band not related to the virus structure.
Our positivity criteria was as been already described above plus any other virus-related band present. The assay gave us the following results. 41 positive, 22 negatives and 8 indeterminated serum samples. The positive pattern showed bands gp160/120 present in 100% of the cases; p65 in 95%; p55 in 51%; p51 in 95%; gp41 in 97.6%; p31 in 73%, p24 in 75.6% and p18 in 31.7%. We also detected in the 8 indeterminated samples a constant pattern; this corresponded to one band around 50-55 Kd which as not been related to the HIV structure, by its appereance - rather diffuse- we presumed could correspond to some glycoprotein. These 8 samples coming from patients with repeated blood transfusions (4), patients with chronic renal failure in dialysis (2) and patients with connective tissue disease (2). Using an IFA test (Frappier Diag. USA) all western blot positive samples, but one, gave also positive results. The 8 inespecific ones also gave inespecific results using this procedure.
The use of a supplemental test as the EPIblot-HIV allowed us to diagnosticate HIV infection in 41 of 70 serum samples whose previous EIA screening test were positive. For indeterminated samples there is a constant pattern, a protein band around 50-55 Kd. We use a more stringent criteria than the recommend due to band gp 41 is present only in 97.5% of the cases and band p24 in 75.6 % of the cases.

B.540 INCREASED ADA ACTIVITY IN CHILDREN WITH PERINATAL HIV INFECTION

Palomba, Elvia; David, O.; Gabiano C. and Tovo P.A.
Istituto di Clinica Pediatrica, Universita' di Torino, Torino, Italy.

Objective. To evaluate whether adenosine deaminase (ADA) activity is enhanced in erythrocytes of children with perinatal HIV infection and its possible prognostic significance.
Methods: ADA was assessed, according to Hopkinson's method in RBC of 33 children born from HIV+ mothers (8 P2, 13 P1, 12 P0) and in a control group of infants and adults. RBC of normal donors were also incubated for 1 hr, before ADA evaluation, with serum samples of children who showed high values of enzyme activity.
Results: The ADA levels were significantly higher in infected symptom-free (P1) children when compared to those of the control group (0.34 ± 0.01 vs 0.25 ± 0.06 U/ml RBC, p = 0.001). A futher significant increased was found in symptomatic (P2) children (0.45 ± 0.02 U/mlRBC, p<0.01 vs P1). The enzyme activity was enhanced also in the group of (P0) infants, with indeterminate state of infection (0.29 ± 0.03, p<0.05 vs controls). The enzyme values of normal RBC did not increase after incubation with positive serum samples.
Conclusions: Our results demonstrate that ADA is significantly increased in RBC of perinatally infected children, as previously reported in HIV + adults. High ADA levels may be an early, though indirect, marker of infection of possible prognostic significance, because the enzyme activity is related to the progression of the disease. Since the increased ADA values are not induced by serum factors, the infection of erythroid cells by HIV might account for the enhanced enzyme activity.

B.541 WESTERN-BLOT QUANTITATIF : INTERET DANS LA SURVEILLANCE DES PATIENTS HIV-SEROPOSITIFS

Schiavini D., Puel Jacqueline
Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE

Objectifs. Evaluer l'intérêt d'une quantification du Western-blot.
Méthodes. Les bandes d'immunoblot obtenues (Du Pont De Nemours)sont quantifiées par lecture densitométrique automatisée (Electrophoresis Data Centers-Helena). Les résultats sont exprimés en intégrales représentatives de la surface délimitée par chaque pic de la courbe.Deux groupes de 9 patients appariés d'après l'âge,la sexualité et le stade clinique(défini par le CDC) ont été constitués: le groupe Malades(M) formé de sujets ayant progressé du stade II au stade IV, et le groupe Témoin(T)de malades restés asymptomatiques(stade II)durant le même suivi de 24 à 31 mois.
Résultats. Cette technique assure une lecture objective.Elle permet un suivi précis des différents anticorps:ainsi les valeurs représentatives des Ac anti p24 et anti-p17 sont plus faibles dans le groupe M que dans le groupe T ($p<0,05$) et décroissent jusqu'à s'annuler au cours du suivi;chez un malade traité par AZT, ces 2 valeurs augmentent alors que l'antigénémie p24 disparait.Sa sensibilité est supérieure à celle des tests EIA de 2ème génération(ENVACOR Abbott) pour la détection des anticorps anti-p24.Sa reproductibilité intrasérie est bonne. Cependant elle pose des problèmes méthodologiques (défaut de reproductibilité intersérie)nécessitant l'apport d'améliorations.
Conclusion.Les perspectives sont intéressantes dans l'évaluation précoce de l'évolutivité de la maladie chez les sujets asymptomatiques, dans le suivi des nouveaux-nés de mères séropositives et dans la surveillance du traitement antiviral.

B.542 MODUL SYSTEM IN HIV-ANTIBODY TESTING FOR BOEHRINGER MANNHEIM ENZYMUN-TEST(R) DIAGNOSTICS

H. Bayer[1], M. Lin[2], Ch. Klein[1], P. Kirch[1]
[1] Boehringer Mannheim GmbH, Forschungszentrum, D-8132 Tutzing, FRG
[2] Chinese Academy of Preventive Medicine, Beijing, P.R. China

Screening tests have to be sensitive for possibly all specificities of HIV-antibodies, while specific antibody tests are important for prognosis of diseases (p24) or distinguishing HIV-I from HIV-II-infection.
For our automatical Boehringer Mannheim Enzymun-Test(R)-System we developed a modul-system using a single universal biotin binding solid phase in all tests and combination of specific biotin labelled antigens for the individual tests.
Polystyrene tubes were coated with streptavidin. Recombinant antigens were labelled with biotin. Synthetic peptides were synthesized by solid phase technology.
The samples were incubated with the antigens in PBS containing bovine serum. Solid phase bound complexes were detected by peroxidase labelled second antibodies and visualized using ABTS(R) substrate. We showed that the modul system is suited for detection of p24 specific antibodies in a quantitative test with the linear standard curve in high precision (< 3 %) as well as for screening tests to HIV-I and HIV-II using recombinant HIV-I gp41 and p24 antigens and synthetic peptides from HIV-II gp32.

B.543 OKT4 EPITOPE DEFICIENCY AND SYMPTOMATIC IMMUNE IMPAIRMENT MIMICKING AIDS.

Van de Perre, Philippe* and Lepage, P.**

*Programme National de Lutte contre le SIDA, Kigali, Rwanda and **Department of Pediatrics, Centre Hospitalier de Kigali, Kigali, Rwanda.

Case Report: The patient was a 14-year old girl presenting with disseminated cutaneous candidiasis, severe pain on left foot and persistent diarrhea. A X-ray film of the left foot revealed an osteitis lesion of the calcaneum suggestive of tuberculosis. Massive infestation of stool samples by *Giardia lamblia* was disclosed. The patient had no risk factors for HIV infection. She was virgo and had no history of blood transfusion. She was seronegative for HIV by both EIA and WB. Normal absolute number of Peripheral Blood Lymphocytes (PBL) of 1860 / microL was counted. Complete cutaneous anergy to tuberculin (10 IU purified protein derivative), candida, and phytohemagglutinin 1 and 10 microGr was found. B lymphocytes were quantitated by means of a direct immunofluorescent assay (IFA) and found to represent 36% of the total PBL. T-cell subsets were identified by means of an indirect IFA using monoclonal antibodies (MoAb; OKT3, OKT8, OKT4 and OKT4A which is directed to a distinct epitope of the CD4 molecule; Ortho Diagnostic Systems). The following values for T-cell subsets were found: OKT3+, 69%; OKT8+, 21%; OKT4+, 4%; OKT4A+, 56%. The calculated OKT4:OKT8 ratio was 0.2 but the OKT4A:OKT8 ratio was 2.7, clearly indicating OKT4 epitope deficiency (OKT4 ED).

Conclusions: In contrastto many other cases of OKT4 ED, our patient had profound T-cell function impairmentsand experienced clinical consequences of these dysfunctions which were initially believed to be HIV-associated. We feel that a monoclonal antibody directed to a CD4 other than the T4 should be included in the T-cell subset identification of patients with a suspicion of HIV infection. A significant decrease in T4 epitope recognition by the OKT4 MoAb has been observed in as many as 20% of American blood donors***. However, only 1/127 asymptomatic pregnant women (0.8%) enrolled in an ongoing cohort study on perinatal HIV infection in Kigali presented with this congenital defect. Our observation suggests that OKT4 ED could be accompanied by symptomatic T-cell dysfunctions. We also suggest that the frequency of this congenital abnormality is not homogeneously distributed in people of African origin.

***Casey TT et al. Arch Pathol Lab Med 1986; 110: 702-704.

B.544 PERIPHERAL BLOOD LYMPHOCYTES (PBL) FORMING ROSETTES WITH THEIR AUTOLOGOUS ERYTHROCYTES (AE)-(AELFR) IN HIV INFECTED PATIENTS.

Pathouli Christina+,Spiliotopoulou J.++,Kontopoulou-Griva Ir.++.
+Athens University, Athens, Greece, ++1st Regional Transfusion Center, Hippocration Hospital, Athens, Greece.

Objective.we observed that a small part of normal PBL 8-14% forms spontaneous rosettes (R) with their AE in Man. We wanted to investigate how is this phenomenon in individuals infected by HIV. We studied 23 Hemophiliacs positive for HIV and 22 individuals infected by HIV and/or suffering from AIDS.

Methods.PBL were separated according to classic techniques. AE suspensions 1% were prepared and the mixture (V/V) were observed by microscopy after incubation for 24 hours in 4°C temperature.

Results.We found AELFR from 50% till 97% and we were able to inhibit the R formation by using monoclonal antibodies (MA) from "Dakopatts": T_1, T_2, T_4, T_8, B after addition of them into the mixture. The inhibition was strong by T-MA and very low by B-MA except for one case: a patient with Coombs positive hemolytic anemia (A).

Conclusions.We may until now conclude that a small numeral of PBL are able to attack against their AE in order to eliminate old or altered E from blood stream. Probably this PBL subpopulation may increase in pathologic states like HIV infection so as become dangerous for normal AE.It is posible this mechanism to be partially responsible for the A, wich A develops later in such patients.

B.545 MULTIDISCIPLINARY APPROACH TO HIV SEROPOSITIVE PATIENTS: A TWO YEARS EXPERIENCE OF AN OUT-PATIENTS DEPARTMENT.

Giorgio Barbarini, A. Maccabruni, A. Malfitano, W. Calderon, A. Parisi, F. Tacconi.
Clinic of Infectious Diseases. IRCCS S. Matteo - University of Pavia ITALY

Objective: To give a complete response to increasing needs of HIV seropositive subjects.

Methods: Since 1986 in the Clinic of Infectious Disease of Pavia, a special out-come patients Department was established for ambulatory management of HIV infected subjects. In this structure are always present an infectivology, a neurologist and a psychologist; many other specialists (hematologist, pneumologist, oculist, pediatrician, obstetrician and dermatologist) are available every day; they are working, as agreement with their Clinics, in our structure.

Results: There is one diagnostic-therapeutical protocol for every specialist; all these protocols are coordinated by an infectivologist, chief of the department. Thre is also an endoscopy room, where it's possible to make bronchoscopies, recto-colonscopies, gastroscopies and hysteroscopies.

Conclusion: The polymorphism of symptoms in HIV positive patients requires a multidisciplinary approach. In our Clinic we established an ambulatory menagement; we think to give in this structure complete responses to medical and psychologycal needs of HIV positive patients.

B.546 UNE CAUSE INHABITUELLE DE DIARRHEE CHEZ UN PATIENT VIH POSITIF

Annick DATRY, T. Similowski, M. Rosenheim, C. Katlama, D. Fassin, M. Gentilini - Dpt de Santé Publique, Parasitologie et Médecine Tropicale et Unité INSERM 313, Paris, France.

Objectif. Les auteurs rapportent une localisation inhabituelle leishmanienne, oesogastroduodénale chez un patient VIH positif apyrétique présentant une dysphagie, des douleurs rétrosternales, des épigastralgies associées à une diarrhée intermittente.

Méthodes. Des biopsies oesophagienne, gastrique et duodénale sont réalisées. Les différents échantillons sont apposés sur lame et colorés au Giemsa.

Résultats. Les biopsies révèlent une infestation massive leishmanienne dans cette surprenante localisation oesogastroduodénale. Il existe une candidose oesophagienne associée. Aucune autre infection opportuniste n'est retrouvée. Un frottis médullaire et une biopsie cutanée montrent de rares leishmanies.

Conclusion. La leishmaniose digestive massive est inhabituelle dans les leishmanioses viscérales disséminées des patients VIH+. Cette observation incite le biologiste à une recherche exhaustive de tous les agents opportunistes pouvant compliquer l'infection VIH.

B.547 MULTIPLICATION OF HHV-6 AND HIV1 IN BLOOD LYMPHOCYTE CULTURE

Agut, Henri*; Kerouedan, D.**; M'Pele P.***; Collandre, H.****; Rosenheim, M.**; Huraux, J.M.* et al.
*Laboratoire de Bactériologie-Virologie, Hôpital de la Pitié-Salpêtrière, Paris, France, **INSERM U313, Paris, France, ***Hôpital Général, Brazzaville, Congo, **** Unité d'Oncologie Virale, Institut Pasteur, Paris France.

Objective. To detect the simultaneous multiplication of HIV and human herpesvirus-6 (HHV-6) in primary lymphocyte culture from patient's blood.

Methods. Peripheral blood mononuclear cells (PBMC) were grown in primary culture according to conventional procedures. Secondary cultures were performed with freshly stimulated lymphocytes from a healthy donor. HIV production was evidenced by enzyme immunoassay and reverse transcriptase activity. HHV-6 was detected by molecular hybridization.

Results. During an attempt to isolate HIV1, PBMC from a Congolese AIDS patient exhibited a typical HHV-6 cytopathic effect whereas both HIV1 antigen and HHV-6 hybridization signal were detected in culture supernatant. In addition, cell-free supernatant could transmit mixed infection by HIV1 and HHV-6 to PBMC from a healthy donor. However, reverse transcriptase activity was not detectable in primary culture and sequential cocultures starting from the primary culture led to the exclusive multiplication of HHV-6. This suggests that the potent cytocidal effect of HHV-6 progressively inhibited the replication of HIV1 by means of lymphocyte destruction.

Conclusion. Cocultivation of HIV1 and HHV-6 can be observed in primary lymphocyte cultures from AIDS patients. This finding could contribute to the debate on the possible cofactorial role of HHV-6 in AIDS.

B.548 A SYNTHETIC PEPTIDE ELISA FOR DETECTION OF ANTIBODIES TO HIV1.

Libonatti,Osvaldo*; Torstensson,R**; Mhalu,S***; Biberfeld, G**; and Wigzell,H*.
*Karolinska Institute,Stockholm,Sweden,**National Bacteriological Laboratory Stockholm,Sweden,***Muhimbili Medical Center,Dar Es Salaam,Tanzania.

Objective.To synthesise and evaluate a peptide to be used in a diagnostic immunoassay.

Methods.Hydrophilicity and the presence of two cysteines in close proximity were determinants to select a conserved sequence among different isolates of HIV1 derived from the transmembrane glycoprotein gp41. A twelve aminoacid peptide (env 593-604;Leu-Gly-Ile-Trp-Gly-Cys-Ser-Gly-Lys-Leu-Ile-Cys) was synthesised using solid phase methodology.High pressure liquid cromatography showed a purity of 81% w/w peptide.ELISA polystyrene plates were coated with 5µg of peptide per well and air dried at 37°C overnight.Sera were tested at a dilution 1/10 and incubated with alkaline phosphatase conjugated rabbit antihuman IgG and p-nitrophenyl substrate.The plates were read at 405 nm.

Results.The peptide was evaluated using a panel of 266 negative and 35 HIV1 positive Swedish sera and 395 blood donnors sera from Tanzania of which 26 were HIV1 positive.The cut off point was determined as two times the mean value of the negative Swedish sera.A specificity of 97.7% and a sensitivity of 100% was found for the Swedish panel.The african panel showed a specificity of 90.2% and a sensitivity of 92.3%.

Conclusions.A good sensitivity specially for the Swedish sera was found. A further improvement of the technique should allow the use of this peptide for routine diagnostic.

B.549

CONCORDANCE OF POLYMERASE CHAIN REACTION (PCR) WITH HIV ANTIBODY (Ab) IN HIV INFECTION

Horsburgh, C. Robert*; Ou, C-Y.*; Jason, J.**; Holmberg, S.*; Evatt, B.**; Jaffe, H.*; et al.
*AIDS Program, and **Division of Host Factors, CDC, Atlanta GA USA.

Objective. To evaluate the correlation of PCR detection of HIV DNA and detection of HIV Ab.

Methods. We examined peripheral blood mononuclear cells (PBMC) and serum from 112 homosexual men, 85 hemophilic men, 30 HIV-infected transfusion recipients, and 91 heterosexual partners of HIV-infected persons in 5 prospective studies of HIV infection. PCR+, Ab- subjects who seroconverted at the subsequent test date and one who died of a stroke before a followup specimen could be obtained were excluded. PCR was performed using a gag region primer pair (SK38/39). Selected PBMC were also tested with env region primers (SK68/69 or CO71/72). Amplified HIV DNA was detected using specific oligomer probes.

Results. Of 104 HIV Ab+ persons, 91 (88%) had HIV DNA by PCR (86 were gag+ while 5 were gag- but env+). Of 214 HIV Ab- persons, 2 (1%) had HIV DNA by PCR. These were 2 homosexual men who have each subsequently been HIV Ab-, PCR-, and clinically well for 3 years. Analysis of HLA genotypes of the specimens is in progress.

Conclusion. PCR detects HIV DNA in PBMC of most HIV Ab+ persons; detection is increased by use of multiple primer pairs. Some HIV Ab+ persons may have HIV DNA in PBMC which is below the level of detection of PCR. PCR positivity without Ab may represent specimen mislabelling, false positive test results, or, less likely, transiently detectable HIV DNA.

B.551

ETIOLOGY OF INDETERMINATE HIV WESTERN BLOTS.

Celum, Connie*, Coombs, RW*, Lafferty, WE**, Egan, R***, Sninsky, J****, Holmes, KK*, et al.*Univ of Washington, **Washington Dept Social & Health Services, ***Dupont Glasgow Research Lab, ****CETUS Corp.

Objectives. To ascertain the etiologies of indeterminate HIV Western blots (IWB), the rates of seroconversion and sexual transmission, and the yield of supplemental HIV diagnostic tests.

Methods. Thirty-seven individuals with positive HIV ELISAs and IWB and their current sexual partners were enrolled from diverse HIV testing sites in Washington state in an ongoing prospective study. Eighty % were from low and 20% were from high-risk groups. Serologic assays were performed for HIV, HTLV-1 and other retroviruses, hepatitis B, and autoantibodies (antinuclear antibodies, rheumatoid factor, VDRL). Supplemental HIV tests were performed: HIV culture by University of Washington, radioimmunoprecipitins assay (RIPA) by Biotech, recombinant envelope antigen ELISA (ENV 9) by Dupont, recombinant core/pol/env antigen ELISAs (HIVAGEN) by SmithKline Bio-Science, and HIV polymerase chain reaction (PCR) by CETUS.

Results. Reactivity on Western blot was in the gag only region in 76% of cases. Autoantibodies were found in 29% and hepatitis B surface and core antibodies were positive in 25% of the cases. All were negative for surface antigen. One of 26 cases was indeterminate on HTLV-1 Western blot. Gag and pol reactivity was confirmed by HIVAGEN recombinant ELISA in 20 of 27 (74%) cases and envelope reactivity in 1 of 30 (3%) cases by ENV 9 ELISA. RIPA was negative in 12 (48%) and indeterminate in 13 (52%) cases, primarily with weak p55 and gp 120 reactivity. Only 1 of 29 cases (a homosexual male) was HIV PCR positive. HIV cultures in that case and 21 others have been negative. None of 17 cases with 6 months or greater follow-up have seroconverted. All 17 sexual partners who were tested have been HIV ELISA negative, but 7 of 15 (46%) tested by Western blot were indeterminate. Of the 7 sexual partners with IWB, all were low risk for HIV and 2 had the same WB bands as their partner.

Conclusions. Indeterminate HIV Western blots were not related to HIV infection or HLTV-1 cross-reactivity in this cohort with HIV gag reactivity (22 negative HIV cultures and no seroconversions at 6 months in 17 cases). The significance of IWB in ELISA negative sexual partners is unknown. Cross-reactivity due to other human and animal retroviruses is under investigation.

B.553

RESULTS OF NEUTRALIZATION ASSAYS AND USE OF THE VRL CORRECTION FACTOR WITH THE ABBOTT AND DUPONT p24 ANTIGEN ELISAs.

Arens, Max and Storch, G. Washington University School of Medicine, St. Louis, Missouri.U.S.A.

We compared DuPont (NEK046) and Abbott p24 antigen ELISAs using 35 serum samples found to be positive for p24 antigen by 1 or both assays. Of the 35, 34 were positive (>10 pg/ml) by DuPont and 27 were positive by Abbott. However, 12 of the samples initially positive by DuPont failed to neutralize using DuPont confirmatory reagents, compared to only 1 initially positive by Abbott that failed to neutralize using Abbott confirmatory reagents ($P<0.01$). The 12 samples that failed to neutralize with the DuPont reagents included 8 negative by Abbott, the 1 that was initially positive by Abbott but failed to neutralize, and 3 that were positive by Abbott and did neutralize.

We have also compared the quantitative determination of p24 antigen in the two assays both before and after application of a correction factor developed by the Virus Reference Laboratory (VRL) of the AIDS Clinical Trials Group. For this comparison, we used 21 samples that were positive and neutralizable in both assays. All results were calculated using the VRL standards (25-200 pg/ml) and data reduction software developed by Dataworks Development. The mean and SD of the 21 samples using the Abbott assay were 140±95 pg/ml uncorrected and 98±67 pg/ml corrected. The corresponding results for the DuPont assay were 97±78 uncorrected and 114±96 pg/ml corrected. The r^2 values were 0.43 for the uncorrected results and 0.44 for the corrected values.

The frequent occurrence of non-neutralizable positives using the DuPont assay is a problem that may prevent the recognition of some truly positive samples. Even with the use of the VRL correction factor, substantial differences persist in the quantitative results of testing individual samples with the two assays.

B.550

A RETROSPECTIVE ANALYSIS OF DISEASES ASSOCIATED WITH INDETERMINATE HIV WESTERN BLOT PATTERNS

Drabick, Joseph J., Horning, L., Lennox, J., Coyne P., Knight R., Dillard T., Burke, D., Fuller, S., Damato, J., and the Walter Reed Retrovirus Research Group, Walter Reed Army Medical Center, Washington, D.C., United States of America

Some individuals possess antibodies reactive to HIV Western blot proteins in patterns not diagnostic of HIV infection. A retrospective chart review of patients exhibiting such antibodies was performed and compared to a control cohort of sex and age matched individuals from the same base population of HIV-negative blots to determine if such blots were associated with any specific disease states. 21 such patients were found in a total population of 816 (2.6%). GAG-only (core) blots made up the majority, 79% (23/29). An indeterminate blot was statistically associated with Hashimotos thyroiditis ($p<.01$) and Non-Hodgkins lymphoma ($p<.05$). Kikuchis disease and malignant histiocytosis were associated but the numbers of subjects were too small to reach statistical significance. Indeterminate Western Blots, blots for HIV could be explained by antibodies reactive with non-viral antigens or could represent antibodies to as yet uncharacterized retroviruses, cross-reactive with HIV.

B.552

USE OF VITREOUS HUMOUR OF THE EYE FOR HIV ANTIBODY TESTS OF MEDICOLEGAL AUTOPSIES

M-L Kantanen, H Brummer-Korvenkontio, PJ Karhunen, A Penttilä and P Leinikki. National Public Health Institute and Department of Forensic Medicine, University of Helsinki, Helsinki, Finland

Background. In a HIV surveillance study all medicolegal autopsies have been tested in Helsinki area (N=3558). Since serum is often hemolysed and difficult to run in the standard tests we tried other fluids for sample material.

Objective. To evaluate vitreous humour as sample material for HIV antibody tests of medicolegal autopsies.

Methods. Wellcome's and Abbott's recombinant EIA:s were used as primary tests for HIV-antibodies. Confirmation was done with standard western blots. Sera, vitreous humour and gall bladder fluid were collected from a HIV positive case and the results compared to negative cases.

Results. Vitreous humour gave a positive result in both EIA tests, although the signal was weaker than for sera. WB showed typical pattern with reactivity against all major components of the virus. No indication of nonspecific background reactivity was observed.

Conclusion. Vitreous humour can be used for HIV antibody assay using standard commercial EIA tests. Comparison of the sensitivity of different tests will be presented.In autopsies the material is easy to obtain and does not have the drawbacks of serum samples which are often severely hemolysed.

B.554

FALSE-NEGATIVE RESULTS IN HIV-DETECTION ASSAYS DUE TO SAMPLE DISTRIBUTION

Buimovici-Klein, Elena and Lange, Michael; St. Luke's-Roosevelt Hospital Center; Columbia University; New York, New York U.S.A.

Objective. Only a small proportion of lymphocytes carry virus in HIV-infected persons. This proportion might be related to the severity of the disease. The number of HIV carrying lymphocytes necessary to elicit a positive response in virus culture assays is unknown, but is likely to be higher than one. Due to the Poisson distribution of virus-infected cells, smaller blood samples from subclinical infected persons may yield negative results in reverse transcriptase (RT) or p24 assays. It can also be safely assumed that the smaller the number of infected cells the longer the time necessary to detect virus activity in cocultivation assays.

Method. Blood from 3 asymptomatic HIV-positive (AS) and 3 AIDS patients were cocultured as a single large (20cc) and divided into 6-10 small samples (9-10cc each). The cultures were established, stimulated with PHA and cocultivated with donor lymphocytes. Supernatants were checked every 4 days for presence of p24. Cocultures were carried for 35 days.

Results. All large samples were p24 positive; mean time required to detect p24 ag in samples from AIDS patients was 4 days compared to 16.5 days for AS patients. All small samples from AIDS patients were positive within 7 days of cocultivation. In contrast only 25-67% of small samples taken from AS patients were p24 positive. The first positive samples were observed between 12 & 31 days following coculture.

Conclusion. The results suggest caution in the interpretation of negative results in HIV antibody positive persons when small volumes (≤10cc) of blood are tested. The results suggest that there is strict need for standardization of the methodology of coculture as a means of monitoring response to antiviral therapy.

B.555

HIV Antigenemia in Patients with AIDS and HIV Infection: A Comparison Between Racial Groups.

Fuchs, Edward; Hendricksen C; Farzadegan H; Bartlett J; Quinn T; Chaisson R E
The Johns Hopkins University , Baltimore, Maryland U.S.A.

Objective: To determine if HIV p24 antigen(Ag) differs in white and black American patients, as has been suggested in African and European patients.
Methods: 193 consecutive patients with AIDS or HIV infection who presented for clinical trials were studied; 164 had evaluable results. HIV-Ag was measured by the Abbott EIA and verified by neutralization assay. CD4 counts were performed by flow cytometry. Patients were classified by clinical diagnosis and by CD4 counts.
Results: Overall, 32/132 (24%) of white patients and 7/32 (22%) black patients were HIV-Ag+ (p=NS). Specific results are as follows:

	White			Black			
	Ag+	Ag-	%+	Ag+	Ag-	%+	p value
AIDS	27	16	63	7	8	47	0.55
Non-AIDS	15	74	17	0	17	0	0.29
CD4 < 200	28	19	60	6	8	43	0.42
CD4 > 200	12	71	14	0	16	0	0.20

A higher proportion of white non-AIDS patients (30%) were symptomatic than black non-AIDS patients (6%; p=.06).
Conclusion: The prevalence of serum HIV-Ag does not differ between clinically comparable white and black populations, regardless of clinical status or CD4 number. Prior observed differences cannot be explained by racial variation and suggest that perhaps geographic factors or difficulty in diagnosing AIDS in developing countries may play a role.

B.556

TRADITIONAL EIA AND RAPID SCREENING FOR HIV1 CONFIRMED BY COMBINED TESTING FOR ANTIBODIES AND ANTIGENS

S. Castriciano, C. Calvert, J. Mahony and M. Chernesky.
McMaster University Regional Virology Laboratory, St. Joseph's Hospital, Hamilton, Canada.

Objective. A total of 14 sera from well defined patient infections (5 AIDS, 1 ARC, 4 asymptomatic; 4 negative) were used to evaluate 15 commercial kits for HIV antibodies and another 3 for antigens.
Methods. Antibody tests included 6 EIA's (Abbott, Organon, Dupont, Genetic Systems, Wellcome and Cambridge), 3 Western Blots (Dupont, Virion, BioRad), 2 Microscopy tests (Virion Immunoflourescence, IF and immunoperoxidase, IP) and 4 rapid assays (Abbott passive hemagglutination (PHA) and Testpack; Dupont HIVCheck and Cambridge latex agglutination (LA). Sera were tested for antigens using tests from Abbott, Coulter and Organon.
Results. All 6 EIA screening tests were in agreement on 11 sera (8+3-). Discordant results were seen in an antigen positive AIDS patient, an asymptomatic patient with a single p24 band and an HIV2 positive patient. EIA results were confirmed by WB, IF or IP except for these 3 problem sera. The IF and IP tests mimicked WB results closely. Antigen testing which showed no discordance in this series, provided a better understanding of discordant antibody test results. The rapid antibody tests were accurate except for HIVCheck which demonstrated a problem with sensitivity.
Conclusion. A combination of confirmatory tests such as WB and IF or IP can provide added assurance on interpretation and reporting of difficult sera.

B.557

ABSENCE DE SEROCONVERSION APRES UNE MENIGITE DE PRIMOINFECTION A VIH.

Patey, Olivier*; Dublanchet, A.**; Israel, G.***; Dormont, D.***; Lafaix, C.*
* Service des maladies infectieuses et tropicales, ** Laboratoire de microbiologie, Villeneuve St Georges - France, *** Laboratoire de neuropathologie et de neurovirologie, CEA, Fontenay aux Roses - France.

Objectif : Suivi sérologique et virologique du VIH chez un homme de 26 ans ayant présenté une urétrite aigüe, une ulcération génitale et une méningite de primo-infection à VIH 10 jours après un premier et unique contact hétérosexuel avec une prostituée.
Méthodes : sérologie ELISA VIH1 et 2, RIPA, immunofluorescence, Western Blot, recherche d'anticorps antiprotéine nef, antigènémie P24, culture rétrovirale à partir de lymphocytes du sang périphérique avec mesure de l'activité transcriptase inverse, PCR (en cours).
Résultats : Tous les examens répétés sur 10 mois sont restés négatifs hormis une positivation transitoire du Western Blot à J40 après le contage (P18, P25, Gp120, Gp160) et la culture rétrovirale à 3 reprises (J40, J134, J280). Le patient est asymptomatique et séronégatif à 1 an.
Conclusion : Cette observation confirme la possibilité de transmission du VIH après un contact hétérosexuel unique, favorisée par les maladies sexuelles associées. L'infection à VIH apparait dans certains cas impossible à détecter par les techniques usuelles pendant des périodes prolongées risquant ainsi de favoriser la dissémination du virus. Des études sont actuellement en cours pour caractériser le virus et le statut immunitaire du patient.

B.558

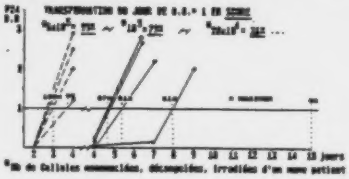
LE RÉTROVIRUS FORMÉ/EXPRIMÉ CHEZ SON PORTEUR EST SEMI-QUANTIFIABLE À PARTIR DES CELLULES MONONUCLÉÉES (CMN) DU SANG

Mathez, Dominique*; Paul, D.**; Saurin W.*** et Leibowitch J.*.
*Hopital Raymond-Poincaré/Université René-Descartes, Garches/Paris-ouest, France; **Abbott Laboratories, North Chicago, Etats-Unis; ***Institut Pasteur, Paris, France.

Objectifs: quantifier le rétrovirus présent dans les CMN du patient au moment du prélèvement de sang sans tenir compte des HIV génomiques non transcrits/traduits in vivo (infection productrice versus infection latente).
Méthode: les CMN (ficoll) congelées de sujets HIV+ sont décongelées, irradiées (60000 r.) et cultivées à 500, 100, 20x10.3 (4 répliques) avec 700x10.3 PHA-blastes normaux + IL2/SVF/RPMI. Le matériel rétroviral qui se propage dans la culture devait être présent dans les CMN in vivo, avant blocage des divisions-maturations cellulaires ex vivo.
Résultats: la vitesse de positivation de chaque puit (P24 surnageant >D.O 1) est transformée en valeur-score, de allant de 0% (D.O<1 à J15) à 100% (>1 à J3). La moyenne des vitesses pour un spécimen donné est fonction du nombre de cellules irradiées.

Les mêmes donneurs de blastes donnent un CV<20% sur le même spécimen testé à 12-18 mois d'intervalle. Le système titre moins de 5 H9-HIV irradiées.

Conclusions: le niveau d'expression HIV peut être un point de mesure biologique pour le suivi des patients traités par anti- viraux et les porteurs HIV en général (abstracts connexes).



B.559

INTEREST OF COMPUTED TOMOGRAPHY OF THE CHEST (C-CTS) IN 120 HIV-INFECTED PATIENTS (PTS) WITH RESPIRATORY SYMPTOMS (RS).

M.F. Carette, Michel Denis, D. Penaud, C. Mayaud, G. Akoun, J.M. Bigot. Depts pneumology, radiology - Hôpital Tenon - Paris - France.

We evaluated prospectively the interest of C-CTS in 120 HIV-infected pts with RS leading to pulmonary investigations.

All C-CTS were performed in high resolution (1 mm - 512 x 512) and were studied with knowledge of clinical features; data were compared with final diagnosis. First data showed that we had to consider 2 groups according to normal (GI) or abnormal (GII) chest X-ray.

In GI : 1) Normal C-CTS does not exclude T8 lymphocytic alveolitis or opportunistic infection at an early stage. 2) In some cases, C-CTS showed hilar or mediastinal enlargement, usually associated with tuberculosis. 3)In few cases with suppurative bronchitis and sinusitis due to community-acquired bacteria, C-CTS demonstrated bronchial abnormalities.

In GII : Pneumocystis carinii pneumonia (PNC-P) or a localization of Kaposi sarcoma (KS) were usual. 1) PNC.P. appeared as very low intensity diffuse interstitial (and alveolar) opacities, without other abnormalities except cysts. 2) If there was pleural effusion, lymph node enlargement or pulmonary excavation, another diagnosis or an association must be considered. 3) KS appeared as bilateral pleural effusion and peribronchovascular opacities more clearly than on X-ray. It may also appear as a focus or a diffuse nodular pneumopathy.
In conclusion : C-CTS was of a major interest : 1) In GI when there were hilar or mediastinal adenopathies. 2) In GII when there was an association of radiological abnormalities.

B.560

A SENSITIVE AND RAPID METHOD TO DETECT HISTOPLASMA

Lomvardias, Stylianos and Vaidya, Kamini P.
Department of Pathology, Woodhull Medical and Mental Health Center, Brooklyn, New York 11206, USA

Objective. To report a sensitive and rapid method for the identification of Histoplasma in tissues and in body fluids of AIDS patients.
Material. Over a period of 18 months we examined 12 specimens from 7 patients There were 6 alveolar lavages, 2 bone marrow aspirates, 2 peripheral blood smears, 1 liver biopsy and one lymph node biopsy. Cultures were prepared at 37°C and at room temperature.
Method. Touch preparations from solid tissues and smears from fluids are air dried and stained with a modified Wright stain (DiffQuik®). Staining takes less then 30 seconds, the slide is rinsed in water and examined with a water mounted cover slip.
Results. Clusters of oval yeasts occur both free and within macrophages. Extracellular yeasts generally are enveloped by a clear zone, giving the appearance of a capsule. Cells measure from 4x3 to 3x2mu. The cell wall stains purple to blue and the interior is clear except for a crescent or half moon shaped polar body which stains pink to red. Budding is frequent. In every instance cultures yielded Histoplasma capsulatum and antifungal treatment was given.
Conclusion. Histoplasmosis may be diagnosed in a few minutes with this simple inexpensive and sensitive method. Treatment may be intiated with no delay.

B.561

QUANTIFICATION DES ANTI-p25 VIH PAR DENSITOMETRIE SUR ANTIGENE DE RECOMBINANT GENETIQUE (CHIRON RIBA-HIV216).

NOEL, Luc*; HARZIC, M.**; GUERIN, M-C.*; MAISONNEUVE, P*.; GHNASSIA J-C.** et SAINT-PAUL, B*.
* Centre de Transfusion et d'Hématologie, **Laboratoire de Microbiologie, Centre Hospitalier de Versailles, France.

Objectif. Quantifier par densitométrie les anticorps anti-p25 dans un test de confirmation basé sur des antigènes de recombinants génétiques sur phase solide avec mise en évidence des anticorps par une antiglobuline marquée à la peroxidase de raifort (CHIRON RIBA HIV-216, Ortho France) et comparer les résultats obtenus sur les sérums séquentiels de patients avec ceux de la technique utilisée en routine (ABBOTT HIV core recombinant antigen competitive EIA) calibrée sur un sérum de référence permettant le titrage de 1 à 256.

Méthodes. Les bandelettes RIBA CHIRON sont utilisées conformément aux recommandations du fabricant. La lecture est réalisée avec un densitomètre SHIMADZU CS-930. Les anti-p25 sont exprimés par rapport au témoin de révélation IgG fort, présent sur chaque bandelette. Des courbes de dilution (du pur au 1/4000) de sérums fortement positifs en anti-p25.ont été réalisées sur 4 échantillons. Les échantillons séquentiels de 25 patients (84 sérums) ont été étudiés.

Résultats. L'évolution du taux des anti-p25 mesurés par densitométrie se conforme aux résultats connus. La sensibilité de la mesure des anti-p25 par RIBA CHIRON est supérieure à la technique de référence pour les valeurs basses comme pour les valeurs élevées. Chez certains patients les anti-p25 continuent d'augmenter plusieurs années apres la contamination

Conclusions. Un test destiné à la confirmation mais standardisé par l'utilisation d'antigènes de recombinants génétiques et de témoins fournit des indications quantitatives d'intéret pronostique.

B.563

STUDY OF INFECTIONS IN 58 AIDS AUTOPSIES FROM 1985 TO 1988 IN RIO DE JANEIRO, BRAZIL.

Basílio-de-Oliveira, C.A.; Valle, H.A.; Fialho, F.; Quintões,-Eleonora Pe-ti; Miguez, L.A. and Morais-de-Sá, C.A.
Gaffrée & Guinle University Hospital, University of Rio de Janeiro (UNI-RIO) - Brazil.

OBJECTIVE: To demonstrate the main infectious conditions found among 58 autopsies of AIDS patients, and compare the findings among risk groups.
METHODS: The staining techiniques used were: Hemathoxillin-eosin, PAS, Grocott and Reticulin.
RESULTS:

	HS/BS		HEMOF.		OTHERS		TOTAL	
	32 patients		17 patients		9 patients		58 patients	
	n	%	n	%	n	%	n	%
GRAM (+) and (-) Bacteria	11	34.38	10	58.80	3	33.33	24	41.38

Cryptococcus neoformans	1	3.13	4	23.53	-	-	5	8.63
Histoplasma capsulatum	3	9.38	-	-	-	-	3	5.18
M. avium intracellulare	1	3.13	2	11.77	-	-	3	5.18

CONCLUSIONS: 1. Toxoplasmosis was the most important CNS lesion in our material.
2. Glossitis was the most frequent organic alteration caused by association of gram positive and negative bacteria,, papilomavirus and Candida albicans.
3. Tuberculosis is frequent causa mortis of HS/BS AIDS patients.
4. Tuberculosis shows a generalized exaudative character.M.tuberculosis meningitis was rare among our patients.
5. Among the lesions caused by Citomegalovirus we emphasize lung and gastrointestinal tract processes, showing ulcers and perforations in the last.

PRIMARY MALIGNANT LYMPHOMAS OF THE CENTRAL NERVOUS SYSTEM IN HIV INFECTION.

Sacchi Giuseppe*; Zorzi F.**; Baronchelli C.**; Bonetti M.**; Falchetti M.* and Stellini R.***.
1**, 2*** Service of Pathology, 1° Div. of Infectious Diseases***, Spedali Civili Brescia, Italy.

Objective: to describe the incidence of primary malignant non Hodgkin lymphomas (NHL) of the Central Nervous System (CNS) in HIV positive patients.
Methods: the data concern 65 autopsies of full-blown AIDS pts. and 10 stereotaxic biopsies from pts. with expansive endocranial processes with problems of differential diagnostics in inflammatory and neoplastic lesions. Routine stains were employed. Immunohistochemical analysis and phenotypic cell identification failed for autoptic nature of specimens.
Results: post mortem examination of HIV positive-drug addict pts. revealed 6 cases of primary malignant NHL of CNS: at onset of neurologic signs 1 patient was group II, 2 pts. group III and 3 cases group IV-C1 (1986 CDC classification); none had systemic clinical signs of lymphoproliferative disease. P.M. inspection revealed 4 cases of single deep intracerebral mass, 1 case of double cerebro-cerebellar expansive processes and 1 case of encephalitic-like lesion. WORKING FORMULATION (W.F.) classified 5 cases as immunoblastic with plasmocytoid differentiation NHL and 1 case as large non cleaved cell NHL (like the stereotaxic bioptic case). Neoplastic lymphoid cells presented thick perivascular cuffs and spread to subaracnoidal and Virchow-Robin spaces.
Conclusion: 1) Primary malignant NHL represent 10% of all P.M. series. 2) Prevalence of high grade primary malignant NHL (W.F.). 3) The primitive cerebral localization and therapeutic possibilities make stereotaxic biopsies essential in diagnosing these patients.

B.562

A SENSITIVE AND SPECIFIC ANTI HIV 2-ELISA USING AN ENV-DERIVED SYNTHETIC PEPTIDE

Krupka, Udo; Brust, St.; Behringwerke AG, 3550 Marburg, FRG

Objective: To evaluate the efficiency of an ELISA (®Enzygnost-Anti-HIV 2), based on a synthetic peptide corresponding to the gp41 protein of HIV 2.
Methods: 50 µl undiluted specimen are pipetted to 50 µl diluent into each well of microtitration plates coated with 1 synthetic peptide. The incubation over 30' at 37 °C is followed by 4 washings and the addition of 100 µl peroxidase labelled Anti human IgG. After another incubation for 30' at 37 °C and 4 washings, the colour development is performed over 30' at RT using TMB.
Results: Of 71 Anti HIV 2-sera all specimens reacted clear cut positive. Compared to a commercial assay an improved detection limit of factor 4 was found by testing serial dilutions of Anti HIV 2-sera. Only weak cross-reactivities were observed when 182 Anti HIV 1-specimens were tested. From a total number of 1500 negative sera and plasma a specificity of 99,8 % was calculated.
Conclusions: This new ELISA turned out to be highly sensitive for Anti HIV 2 showing only weak cross-reactivities with Anti HIV 1, making this assay best suited to differentiate between Anti HIV 1 and -2.

B.564

ROLE OF HIV IN HUMAN ORAL CAVITY.

Pekovic,Drasko*, Garzon, S.**, Strykowski, H.**, Adamkiewicz, V.W.** and Ajdukovic, D.***
*AIDS Research Center, Biomedco Canada Inc., ** Faculté de Médecine, Université de Montréal, *** Institut Armand Frappier, Montréal, Québec, Canada

Oral health status deteriorates drastically in AIDS patients. The present studies aim at correlating incidences of the presence of HIV in periopheral blood lymphocytes (PBL), gingiva and salivary lymphocytes (SL) with incidences of oral disease.

HIV was searched for in PBL, gingiva and SL obtained from 96 patients at different stages of HIV infection by means of immunofluorescence (IF), post-embedding immunogold electron microscopy (IEM) and culturing techniques. Quantity of HIV positive cells were compared with the incidences and the evolution of oral diseases assessed by-monthly over a period of two years. HIV particles and/or antigens were found in PBL, gingival epithelial cells and endothelial cells, lymphocytes infiltrated in gingiva, as well as in SL. The incidence and the percentage of HIV-containing cells found in gingiva and saliva was significanty higher than in PBL. Incidences of a variety of oral disease can be positively correlated with the number of infected cells in gingiva and saliva.

These findings suggest that: Virus-positive PBL in gingiva receive antigenic and/or mitogenic stimulation by the oral folra resulting in the greater expansion of the virus. This contension is supported by our current studies in vitro of stimulation of production of HIV by oral micro-organs. The presence of HIV in gingiva may be associated with the elimination of the local CD4+ T-cell mediated immunologic barrier associated with a high incidence and severity of a variety of oral disease observed.

NEUROPSYCHOLOGICAL EFFECTS OF EARLY HIV-1 INFECTION: DIAGNOSTIC AND METHODOLOGICAL ISSUES

Ingraham, Loring*; Bridge, P.*; Janssen, R.**; Stover, E.***; Mirsky, A.* and Goodwin, F.****.
*NIMH Intramural, Bethesda, MD, USA, **CDC, Atlanta, GA, USA, ***NIMH, Rockville, MD, USA, ****ADAMHA, Rockville, MD, USA.

Objective. To recommend a common methodological approach for neuropsychological assessment in HIV-1 infected individuals to foster meaningful comparisons among studies.
Methods. Methods used in studies of neuropsychological performance in HIV-1 seropositive individuals were reviewed.
Results. Despite considerable methodological variation observed in studies, investigators generally agree on general domains for assessment. We here recommended specific instruments.
Conclusion. Investigators can optimally contribute to knowledge about neuropsychological effects of HIV-1 by: 1) developing or using markers for disease state in early HIV-1 infection, 2) applying longitudinal designs, 3) using common instruments when assessing the multiple domains that demonstrate sensitivity to the neurotoxic effects of HIV-1, 4) selecting controls appropriate to the design and research question, 5) evaluating and controlling for co-factors such as knowledge of serostatus, substance abuse, and psychiatric symptomatology, 6) reporting results for both observed change (e.g., 1 SD) as well as impairment (e.g., 2 SD), and 7) reporting how impairment affects individuals' daily activities.

B.568

THE INCIDENCE OF A MARKER FOR CHOLINERGIC DYSFUNCTION IN AIDS/ARC

Van Gorp, W., Tulin, S., Evans, G., Satz, P., Freeman, D., and Hinkin, C.
Veteran's Administration West Los Angeles and UCLA School of Medicine, U.S.A.

Objective. A specific pattern on the Wechsler Adult Intelligence Scale–Revised (WAIS-R) associated with cholinergic dysfunction has been reported by Fuld to occur in 50% of patients with Alzheimer's disease and in 50% of younger individuals given scopolamine, while occurring in only 10% of patients with multi-infarct dementia, head injury, depression, and normal elderly individuals. This study sought to determine the incidence of this WAIS-R pattern ("Fuld formula") in patients with AIDS and ARC and the AIDS Dementia Complex.

Methods. The WAIS-R was administered to 116 patients: 40 with AIDS and 76 with ARC. The incidence of the Fuld formula on the WAIS-R was calculated for all patients.

Results. Of the 116 subjects tested, 11 demonstrated a positive Fuld profile pattern on the WAIS-R (9%), not significantly different from the incidence in non-cholinergically deficient patient groups studied to date. However, 8 of the persons with AIDS (20%) demonstrated this WAIS-R pattern, while only 3 of the ARC patients (4%) demonstrated this pattern.

Conclusion. An increased incidence of a WAIS-R pattern associated with cholinergic disruption (scopolamine) and cortical dementia (Alzheimer's disease) was not demonstrated in this sample though a greater number (p.>.05) of more seriously immunocompromised patients demonstrated the profile compared with less immunocompromised patients. These results support prior reports of the specificity of the Fuld formula for dementia of the Alzheimer's type than in other types of dementia, including the AIDS Dementia Complex.

HIV ANTIBODY AND ANTIGEN IN THE CSF OF AN HIV-INFECTED CHILD WITH PROGRESSIVE SPASTIC PARAPARESIS AND COGNITIVE DEFECTS, TREATED BY INTRAVENTRICULAR ADMINISTRATION OF GAMMAGLOBULIN

Calvelli, Theresa*; Belman, A.**; Chowdhury, M.***; Williams, P.*; Vasquez, W.* and Rubinstein, A.*
*Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.; **SUNY at Stony Brook, Stony Brook, N.Y., U.S.A.; ***Bronx High School of Science, Bronx, N.Y., U.S.A.

Objective: To monitor fluctuations in HIV antibody and antigen in the CSF of a perinatally infected child receiving intraventriculer gammaglobulin for the treatment of HIV-associated neurologic defects.
Methods: An Omaya reservior to deliver intraventricular hyperimmune gammaglobulin was inserted at age 3½ (1986). HIV antibody in the CSF was monitored by ELISA and Western Blot of serial samples. HIV antigens were detected using an HIV-1 p24 Antigen Capture Assay and by Western Blot of CSF proteins separated by SDS-polyacrylamide gel electrophoresis.
Results: Appearance of progressive corticospinal tract signs resulting in spastic quadraparaparesis was accompanied by increasing titers of HIV antibody in the CSF. Antibody reactive with an increasing number of proteins was detected from 1985-87, followed by increase in intensity only. p24 concentration has decreased with resumption of infusion of hyperimmune gammaglobulin. The number of HIV proteins detectable in the CSF increased from 1985-1988, with no further increase. The neurologic course stabilized in 1988 with long-tract signs showing little further progression.
Conclusion: HIV concentration or activation may be causally related to the neurologic status. Stabilization of neurologic course was observed concomitant with decrease in HIV p24 and stabilization of antibody titer in the CSF.

B.574

NEURODEVELOPMENT OF INFANTS WITH PERINATALLY-ACQUIRED HIV INFECTION

Wachtel, Renee C.; Holden, W.; Nair, P.; Black, M.; Gratz, E and Johnson, J. University of Maryland School of Medicine, Baltimore, MD

Objective. To determine the effect of HIV infection upon the developing nervous system.
Methods. Twenty infants born to English speaking HIV positive intravenous drug abusing mothers were followed prospectively from birth as part of an ongoing study of perinatal HIV infection. All infants were evaluated every three months on a standard battery of tests including neurologic status, and cognitive, motor and language development.
Results. No significant differences have been found to date between the HIV positivie and control infants in the measures utilized, but subtle neurologic findings may be indicative of subsequent CNS infection.
Conclusion. The continued monitoring of neurodevelopment in infants exposed to HIV infection in the perinatal period is essential to detect early onset of CNS infection and determine efficacy of theraputic interventions.

B.575

MOVEMENT DISORDERS IN CHILDREN WITH PERINATAL HIV INFECTION.

Kaplan,Margaret*,and Bedell,G.*,*State University of New York, Health Science Center at Brooklyn. Infant and Child Learning Center(ICLC),Brooklyn,New York, U.S.A.

OBJECTIVE. To describe specific movement problems observed in children (age birth to five) with HIV infection and appropriate treatment goals and priorities.
METHODS. 22 children admitted to the ICLC since January, 1988 were evaluated by occupational therapists using observation, criterion referenced evaluation and standardized tests.
RESULTS. Multiple movement deficits were identified and provisionally categorized based on clinical factors: 1. Movement deficit associated with increased muscle tone or rigidity, 2. Movement deficit due to muscle weakness, 3. Deficit in eye-hand coordination, 4. Deficit in motor planning. Children with increased muscle tone or rigidity are the most movement impaired and little improvement in functional motor skills is observed. Children with muscle weakness show fluctuating abilities from day to day with an overall loss of motor skills. Children whose main areas of difficulty are motor planning or eye-hand coordination are older, less symptomatic, progressing developmentally in many areas and seem to respond well to therapy.
CONCLUSION. Treatment priorities may change with changes in ability. Some children may be working on remediation of that problem and progression to more advanced activities. If a child becomes progressively weaker or tighter, priorities may be focused on compensation.

B.577

PROPOSAL FOR INTERNATIONAL PERINATAL AIDS PROTOCOLS

Kline, J; Stein, Zena.
HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and G.H. Sergievsky Center, Columbia University, New York, New York, U.S.A.

Objectives: To facilitate international co-operation and co-ordination of research in perinatal AIDS.
Methods: Analyses of reported studies are presented, showing that differences in sample selection, case definition, clinical description, and laboratory procedures limit the pooling of findings from different sites.
Results: An organisational framework and a common core protocol are described that could facilitate pooling of findings. Criteria for insuring comparability and reliability of clinical and laboratory measures are proposed, and approaches to data processing that would permit each site to produce speedy analyses and updates of findings, aspects of which would conform to a common, agree-upon pattern.
Conclusion: It is argued that the current pattern of many investigative groups in one or other country devising and maintaining follow-up studies of infants of seropositive women is inefficient, wasteful of procedures and impedes progress. Achievement of co-ordination in the elements described above would (to some extent) standardise follow-up studies and maximise the usefulness of each set of observations.

B.576

PERIODONTAL DISEASES IN HIV-POSITIVE PATIENTS IS MORE RELATED TO THE NUMBER OF T-4 CELLS THAN TO SPECIFIC MICROORGANISMS

Lucht, Erik*, Heimdahl, A.*, Nord, C.E.**, Bratt, G.***, Berglund, O.****
Depts of Oral Surgery* and Microbiology**, Veneral diseases*** and Infections diseases.**** Karolinska institute, Stockholm, Sweden.

Gingival inflammation (GI) and periodontal disease (PD) were compared in 10 patients with HIV infections without clinical symptoms, 10 patients with ARC, 10 patients with AIDS and 10 healthy non-infected sex and age matched controls. All subjects were investigated regarding supragingival dental plaque, subgingival microflora, GI and periodontal pockets. These parameters were compared between the groups and in relation to the numbers of T-4 cells in peripheral blood. GI and PD were inversely correlated to the numbers of T-4 cells but were not correlated to dental plaque or any specific microorganism. GI and PD increased significantly ($p<0.001$, $p<0.01$) with more advanced HIV-disease.

B.578

DO ANTI-SPERM ANTIBODIES INTERFERE WITH HIV ANTIBODY TESTS?

Ferrera, C.**, Nielsen, I.O.*, Berger, R.E.*, Krieger, M.S.** and Krieger, John N. *
*University of Washington and **Genetic Systems Corporation, Seattle, Washington, USA

Objectives: 1. To determine whether anti-sperm antibodies interfere with HIV-1 antibody test results. 2. To evaluate the performance of a 10-minute, peptide-based antibody test for HIV done in a physician's office.
Methods: Sera from patients undergoing infertility evaluation were tested for anti-sperm antibodies (Isojima, Kibrick or Immunobead) and for anti-HIV antibodies with a rapid test (Genie, Genetic Systems) in a urology clinic laboratory. Specimens were also tested using a whole virus assay for antibody to HIV-1 (Genetic Systems LAV EIA) in a research laboratory. Samples that were repeatably reactive on either test were tested by Western blot.
Results: Of 189 patients (including 31 with high titers of antisperm antibodies), one patient (0.5%) was positive for antibody to HIV-1 on Genie.
Conclusions: 1. The seroprevalence of infection with HIV in patients being evaluated for infertility is low; however, some patients are antibody-positive. 2. High titers of antisperm antibodies do not interfere with HIV-1 antibody tests. 3. The Genie test provides a rapid, single-test format for office HIV antibody testing that requires little technical expertise and no equipment, without sacrificing sensitivity and specificity of results.

B.579 THROMBOTIC THROMBOCYTOPENIC PURPURA(TTP) IN AN HIV-INFECTED CHILD: TREATMENT WITH 1-DESAMINO-8-D-ARGININE(DDAVP) AND INTRAVENOUS IMMUNOGLOBULIN(IVIG).

Church, Joseph A.; Marshall, G. and Laug, W. Childrens Hospital of Los Angeles and U.S.C. School of Medicine, Los Angeles, California, U.S.A.

Objective: To describe therapy of TTP in and HIV-infected child. Method: Case report. Results: After 2 weeks of upper-respiratory infection-symptoms, a 6½ year old boy with Down Syndrome and transfusion-associated HIV infection presented with acute hemolytic anemia. Previous hemograms and blood chemistries were normal. Immune status was stable with CD4+ lymphopenia(524/mm^3) and hyper$_g$IgG(3,193 mg/dl). Laboratory data: Hgb-4.5 g/dl, Hct-12.8%, WBC-20.0 x 10^9/l(79% pmn's, 18% lymphs), nucleated rbc's-81/100WBC platelet count-10.2 x 10^9/l, peripheral smear-consistent with severe microangiopathic hemolysis, urinalysis-2+ protein, 2+ heme, blood urea nitrogen-50 mg/dl, direct and indirect antiglobulin tests-negative. Despite supportive therapy with antibiotics and rbc and platelet transfusions, hemolysis continued, the platelet count dropped to under 5 x 10^9/l and gross hematuria developed. The patient was given DDAVP(0.3 mcg/kg) and begun on IVIG(500 mg/kg daily for 5 days). Promptly thereafter, hemolysis decreased, platelet count improved and hematuria cleared. Three months later his hemogram and blood chemistries were normal. Conclusions: This patient's clinical course indicates that, as in adults, HIV-infected children are at risk for TTP. DDAVP and IVIG may be useful in the termination of the microangiopathic process characteristic of TTP.

B.581 MUCOCUTANEOUS KAPOSI'S SARCOMA: A MARKER OF PAEDIATRIC AIDS.

Edward K. Mbidde; Banura, C. and Kizito A.
Uganda Cancer Institute (UCI) Uganda.

Objective: To describe clinical features of childhood Kaposi's sarcoma (KS) that are diagnostic of AIDS.
Methods: Case records of all children admitted to the UCI with diagnosis of KS between June 1987 and January 1989, were reviewed for features that are suggestive of paediatric AIDS. Evaluation of these children included a history and physical examination. Investigations included a full hemogram, an ESR, chest X-ray, liver function tests, renal function tests, ultrasound of the abdomen and biopsy of either a skin lesion, lymphnode or both. HIV serology was done using Welcozyme kit and western blot for confirmation. Patients were staged according to the staging classification by R.L. Krigel et. al.(Cancer Treatment Reports 1983: Vol. 67, pg. 531-534).
Results: Six children all stage 4 (5 male, 1 female), median 2.5 yrs (range 2-4 yrs) were seen over this 18 mos period. All had histologically confirmed KS and HIV serology with Western blot confirmation in 1 case. 4 were HIV +ve, 1 falsely negative, 1 HIV -ve. The 4 HIV+ve children and the one falsely negative child had mucocutaneous KS in addition to lymphnode involvement. The HIV -ve child had only lymphadenopathic KS.
Conclusion: Disseminated aggressive histologically confirmed KS in children should be considered a marker of AIDS as it is in adults.

B.583 RANULA CYSTS IN CHILDREN WITH AIDS

Anderson, Virginia M*; Lee, H.^; Greco, M.A.°*; Arroyo, A.^. *Pediatric AIDS Study Group, ^SUNY Health Science Center, Interfaith Medical Center Brooklyn NY, °New York University, NY USA

Object: To report the clinicopathologic correlations of ranula cysts in children with AIDS.

Method: Two cases are reported: 1) Patient 1 had lymphadenopathy and lymphocytic interstitial pneumonitis (LIP) at age 1 year and a 3cm in diameter, sublingual, ranula cyst which was excised at age 2. Within 3 weeks it reoccurred only to spontaneously disappear two months later. 2) Patient 2 had LIP with cor pulmonale and hypoxia at age 2 years. Following treatment with steroids, a 1cm in diameter ranula cyst disappeared.

Results: The sublingual excisional biopsy of the collapsed cyst revealed a fibrous shell containing lymphocytes and plasma cells that also infiltrate islands of mixed salivary gland tissue containing ectatic ducts lined by pseudostratified epithelium.

Conclusion: Ranula cyst resembles cystic parotid lymphoepithelial lesions described in adults with AIDS. Ductal obstruction by inflammatory cells is part of the spectrum of steroid-sensitive, extranodal, polyclonal, polymorphic, B cell lymphoproliferation most often presenting as EBV related LIP in children with AIDS.

B.580 GIANT CELL TRANSFORMATION OF THE LIVER IN PEDIATRIC AIDS.

Kahn E*;Daum F*;Greco MA**;Magid M***;Morecki R****;
Anderson V*****.
*North Shore Univ.Hosp.,Manhasset-Cornell Univ.Med.College,NY,NY;
NY Univ.Hosp.,NY,NY;*NY Hosp.-Cornell Univ.Med.College,NY,NY;
****Albert Einstein Med.College,NY,NY;*****NYC Dept.Health,NY,NY,U.S.A.

Objective. Emphasize that giant cell transformation occurs in the liver of children with HIV infection.
Methods. Review of liver tissue of 46 children with AIDS (biopsies =7, autopsies=42).
Results. Giant cell transformation of the liver was seen at autopsy in 4 of 46 children. All 4 had parental IV drug abuse as their risk factor for AIDS.

Pt	Age	Sex	MAI	Inflammation	Cause of death
1	4y	M	+	+	sepsis, DAD
2	8y	F	+	+	resp. failure
3	5mos	M	-	-	resp. failure
4	10mos	M	-	-	resp. failure

Conclusion. Giant cells occur not only in AIDS associated encephalopathy but also in the liver of children with HIV infection. We therefore confirm a previously published report (Witzleben - Hum Pathol 19: 603, 1988) that HIV infection in children may cause giant cell transformation of the liver.

B.582 SIMULTANEOUS OCCURANCE OF PAROTID SWELLING & LYMPHOCYTIC INTERSTITIAL PNEUMONITIS IN CHILDREN WITH HIV DISEASE.

Gupta, Asha, Kaul, A., Shah, K., Groth, E., Chow, J., & Li,K.
New York Medical College, Valhalla, New York, U.S.A.

Over the last 4 years, 110 children under the age of 13 years have been followed at our affiliated institutions. 25 of these children had clinical & radiological evidence of lymphocytic interstitial pneumonitis (LIP). In three of the cases, the diagnosis was confirmed by biopsy. All of the 25 children also had parotid swelling. There was no child in our series who had either of these two physical findings as an isolated finding.

It has been postulated that LIP is caused by Epstein Barr virus induced lymphoproliferation. Children who are exposed to HIV in utero handle EB virus infection abnormally leading to the development of LIP. Adults on the other hand acquire HIV infection after primary exposure to EBV and LIP is a rare occurance in adults. We postulate that parotid swelling may also be caused be EBV infection related lymproproliferation.

Demonstration of EBV genome in parotid gland will be required to support this hypothesis.

We conclude that the findings of parotid swelling and LIP occur simultaneously in pediatric HIV disease. Children who present with parotid swelling should be observed carefully for the development of LIP and LIP should be a consideration in these children if they develop respiratory symptoms.

B.584 SEVERE REACTIONS TO TRIMETHOPRIM-SULFAMETHOXAZOLE IN CHILDREN INFECTED WITH THE HUMAN IMMUNODEFICIENCY VIRUS.

Stephen Chanock*; Luginbuhl,L.*; McIntosh,K.*. *Division of Infectious Diseases, The Children's Hospital, Boston, MA USA.

Adverse reactions to trimethoprim/sulfamethoxazole (TMP/SMZ) therapy occur with greater frequency in patients infected with HIV and commonly involve one or all of the following: leukopenia, thrombocytopenia, and rash. Severe reactions, such as Stevens-Johnson syndrome or seizures, have been reported in several adult patients. We report two congenitally infected children who developed severe life-threatening reactions to TMP/SMZ therapy. An eight month old male was noted to develop fever of 40°C, vomiting, lethargy, a full fonanelle and a combination of a maculopapular and urticarial eruption shortly after beginning a second course of TMP/SMZ. Laboratory investigation failed to identify an alternate etiology. Later, he was rechallenged with TMP/SMZ and developed identical symptoms. A second child, 10 months old, with a history of maculopapular eruption to TMP/SMZ therapy, was rechallenged and shortly thereafter developed vimoting, fever of 38.4°C, and respiratory distress (with a negative chest X-ray). Over the next 24 hours, he developed hypotension, seizures, and a cardio-pulmonary arrest. TMP/SMZ was discontinued and the patient recovered over 96 hours. Over the next five days, the following were noted: glossitis, conjunctival injection and erythema of the palms, soles, and lips, which led to diffuse, superficial desquamation. Investigation failed to determine an alternate etiology. The occurrence of life-threatening reactions to TMP/SMZ therapy should be taken into consideration in the care of children with HIV infection.

B.585 PREDICTIVE MARKERS OF VERTICALLY TRANSMITTED HIV INFECTION: A PRELIMINARY STUDY.

Carosi G.*,Cadeo G.P.*,Caligaris S.*,Casari A.*,Merlini R.§,Duse M.§,Ugazio G.A.§ (* Dpt Infectious Trop. Dis.; §=Dpt Peadiatrics Univ. Brescia, Italy).

Objective. All the children born to HIV+ mothers from jan. '86 to dec. '88 were reviewed to detect any possible early marker of neonatal infection. Results. 16/26 observed cases are presently being monitored and monthly administered i.v. immunoglobulins. 4/16 (aged > 15 mths) became HIV- (6-12 mths), never showed significant alterations in any biochemical, immunological and clinical parameters nor evidence of seric p24. 5/16 (aged < 15 mths) are likely loosing maternal Abs, show weak reactivity to ELISA and indeterminate W.B. patterns. None of them presents any sign of biochemical, immunological, virological nor clinical impairment. Out of the 7 HIV+ children (3 aged > 15 mths; 4 aged <6 mths), 3 are actually showing signs of paediatric AIDS. In all of them seric p24 antigen was present, togheter with precocious (since 6 months of age) immunological impairement (T4 n° > 800/mm2; IgG twice the normal limit) and chronic chronic increase of ESR. None of the 13 healthy cases showed similar alterations at any age.

Conclusion. According to our limited experience, T4 absolute n°, seric immunoglobulin G level, evidence of seric p24 antigen and ESR could represent early markers of congenital infection and disease progression in children born to HIV+ mothers and their role needs to be further investigated.

B.586 COMPARISON OF IMMUNOGLOBULINS AND GROWTH PARAMENTERS AT BIRTH AMONG HIV SEROPOSITIVE AND SERONEGATIVE INFANTS

Butz, Arlene*; Hutton,N.*; Larson,E.*; Joyner,M.*; Vogelhut,J*; and McHugh,J.*
* Johns Hopkins University, Baltimore, Maryland, U.S.A.

Objective. To examine growth and biological data at birth in infants born to HIV seropositive and seronegative mothers in high risk groups (IV drug users (IVDA), sex partners of IVDA).

Methods. Twenty-three infants born to high risk women,enrolled in a 15 month longitudinal study, were examined at birth for immunoglobulins, HIV (antibody) birthweight (BW), and gestational age (GA).

Results. Eleven of the 23 infants (48%) tested HIV positive (+) at birth. Maternal HIV risk factors included: IVDA=65% (N=15); sex partner of IVDA=22% (N=5); and IVDA and sex partner=13% (N=3). No statistically significant differences were observed in immunoglobulins, BW and GA in the HIV seropositive and seronegative infants.

Variable	Mean HIV+	Mean HIV-	ttest	p value
IgG (mgm/dl)	1300.5	1365.5	-.49	.6312
IgM (mgm/dl)	19.2	12.6	1.61	.1357
IgA (mgm/dl)	5.7	5.0	.52	.6100
GA (weeks)	38.5	38.9	-.46	.6513
BW (grams)	2750	2929	-.73	.4760

Conclusions. Immunoglobulins and growth parameters measured at birth do not distinguish HIV seropositive from seronegative infants born to similar risk mothers.

B.587 TREATMENT OF HIV+ DRUG ADDICTS WITH IFN ALPHA 2 RECOMBINANT - PRELIMINARY REPORT

Orlando, Giorgio*; Belletti G.*, Gennaro M.*, Papa D.*, Puppo F.**, and Indiveri F.***
Infectious Disease Dept. USL 2 Sanremo,Italy, **Univ.of Genoa,Italy

Methods. 18 HIV positive patients (16 drug addicts) classified according Walter Reed's classification as 14-WR2; 1-WR3; 2-WR5; and 1-WR6) have been treated since 1987 according to the following scheme: IFN alpha 2a (Roferon) 3xMU/die consecutively for 6 days and for 6 weeks subcutaneously.

Toxicology, collateral effects, clinical and immunological controls were effected every three months.

Results. Up to now 12 patients are still under treatment (min. 18 months, max. 24 months, average 19 months) with excellent compliance and tolerability. From the clinical point of view the disease has slowed down in 9 patients compared to the untreated controls. Three patients have worsened (1-WR6; 2-WR5/6)but these started their treatment in already bad clinical conditions.

We have noticed a diminution of hospital admittance (>50%) and a reduction (about 35%) of opportunistic infective pathology as compared with the control group.

Conclusion. We can assume the treatment with IFN alpha 2a as a possible retardant of the progression of HIV infection, well tolerated and without important collateral effects, even if more data and clinical cases are needed for a cleaner and more precise therapeutical indication.

B.588 NON-MYELOSUPPRESSIVE CHEMOTHERAPY FOR HIV-ASSOCIATED AGGRESSIVE LYMPHOMA

Kennedy, Peter*; Murray, C**; Scolaro, M.*
*Los Angeles Oncologic Institute, Los Angeles, California, USA. **Baylor University Medical Center, Dallas, Texas, USA.

Objective. To demonstrate the efficacy and toxicity of Bleomycin, Oncovin, and Prednisone(BOP)in combination with AZT and Acyclovir in treatment of HIV infected patients with aggressive lymphoma. Methods. Our early attempts to utilize modern, intensive, myelosuppressive chemotherapy in HIV infected patients with stage IIB-IV lymphoma led almost invariably to brisk tumor regression accompanied by profound, prolonged and often fatal myelosuppression. As a consequence, we began a trial of non-myelosuppressive chemotherapy aiming for palliation and continued maximal performance status instead of cure. To date, we have treated five patients, all with stage IIB-IVB biopsy proven large cell diffuse lymphoma using a regimen of q 2-3 weekly Bleomycin (10-15u), Oncovin (1.5-2mg), and Prednisone (60mg/dx5) in combination with AZT (300-1000 mg/d) and Acyclovir (2.4-3.6 gm/d) for a period of 3 to 8 months. Results. All patients have had complete tumor regression determined by physical exams, scans, or re-biopsy for a duration of 4 to 30 months. No pulmonary toxicity has been observed. No apparent increase in opportunistic infection has occurred. One patient developed CNS recurrence (no CNS prophylaxis was given), but otherwise remains in remission. Conclusion. BOP plus AZT and Acyclovir represent a highly effective non-toxic treatment regimen for patients with HIV associated aggressive lymphoma. Longer follow-up is needed to evaluate the durability of these responses.

B.589 CHIMIOTHERAPIE AGRESSIVE (CH.A) DES LOCALISATIONS BRONCHO-PULMONAIRES DE SARCOME DE KAPOSI (LBP-SK) S'ACCOMPAGNANT D'INSUFFISANCE RESPIRATOIRE AIGUE (IRA).

Michel Denis, T.M'Moud, J.P.L'Huillier, F.Parquin, G.Mayaud, G.Akoun. Centre de Pneumologie et de Réanimation Respiratoire - Hôpital TENON - 75020 PARIS - France.

Jusqu'en septembre 1987, l'évolution immédiate des patients (pts) admis dans notre USI pour IRA résultant de LBP-SK était constamment mortelle. Le but de cette étude prospective, débutée à cette date, est d'évaluer l'efficacité d'une CH.A avec ou sans corticothérapie adjuvante, au cours de ces IRA.

. 9 épisodes d'IRA, survenant chez 5 pts infectés par le VIH, ont été traités. Dans tous les cas, l'IRA était sévère : $PaO_2=\overline{59}$ mm Hg (47-68) ; elle résultait de LBP-SK (critères cliniques, radiologiques, endoscopiques et/ou histologiques) sans infection associée (négativité de l'enquête microbiologique).

. Le traitement débuté dans 8/9 cas chez des pts avec PN $>$ 2 500/mm^3 comportait : 1)Au cours des 9 épisodes, une CH.A avec à J1, adriamycine 50 mg IV, vincristine 2 mg IV et bleomycine 15 mg IV, à J8, vincristine 2 mg IV et à J15, vincristine 2 mg IV et bleomycine 15 mg IV ; 2)Au cours de 4/9 épisodes, 1 bolus adjuvant de méthylprednisolone à J1 et J2.

. La CH.A avec ou sans corticothérapie adjuvante, a toujours été efficace sur le plan clinique, autorisant la sortie du pt de l'USI. Au cours de 5 épisodes, la PaO_2 s'est normalisée dans un délai de $\overline{9}$ jours. Au cours des 4 autres, elle s'est améliorée atteignant $\overline{90}$ mm Hg (70-88) en $\overline{15}$ jours.

. Au cours de 6 épisodes, une baisse des PN $<$ 1 000 mm/^{3} est survenue entre J5 et J12 empêchant de compléter la cure de CH.A. Dans 5 cas, $<$ 500/mm^3, elle s'accompagnait de fièvre d'évolution favorable sous antibiothérapie empirique.

En conclusion : au cours des IRA résultant de LBP-SK, une CH.A peut être remarquablement efficace à court terme. Le gain à long terme reste à évaluer.

B.590 DOES HLA BACKGROUND INFLUENCE THE RATE OF PERINATAL TRANSMISSION OF HIV?

Rosemary Hague*;D Kilpatrick¯;J Mok*;PLYap¯;MA Coutts^
*City Hospital,Edinburgh; South East Scotland Blood Transfusion Service, Edinburgh; ^Royal Inverclyde Hospital,Greenock, UNITED KINGDOM

Objectives; To determine whether there is any association between HLA class I and II types and the development of HIV infection in infants born to HIV seropositive mothers.

Methods; 8 HIV seropositive symptomatic children (age 2-5) were studied for HLA A,B and DR types together with 25 children age 1-5 all of whom were HIV antibody negative, clinically and immunologically normal, and therefore presumed un-infected. Both groups had mothers who were HIV seropositive.

Results; We have not been able to confirm any association between the development of symptoms and HLA type such as B35, DR5, A1, B8, DR3 described by other groups. No haplotype was found to be predominant in our infected group. HLA type A3, which is present in 30% of the normal Edinburgh population, was found in none of the infected children, but 12 of the other group ($p < 0.05$).

Conclusion; HLA type does not appear to be a major factor influencing the risk of vertical transmission of HIV. Further studies will be needed to substantiate the weak association we have found between apparent non-transmission and HLA A3.

B.591

EFFICACY AND SAFETY OF KETOCONAZOLE IN HIV INFECTED INFANTS WITH MUCOCUTANEOUS CANDIDIASIS. LeMay, M.D.; Cooper, E.R.; Patel, D.K.; Pelton S.I. Boston City Hospital and Boston University School of Medicine, Boston, Massachusetts, U.S.A.

Mucocutaneous candidiasis is a frequent opportunistic infection in children with HIV disease and associated with significant morbidity (pain, poor feeding, failure to thrive). Recommended therapies such as Nystatin and gentian violet have not been efficacious in immunocompromised hosts with moderate to severe candidiasis. We treated 4 infants, ages 1 to 8 mos. with a Ketoconazole suspension (prepared by pharmacy) of 3 mg/kg q 12 h for moderate to severe thrush (3 patients) which involved buccal mucosa, tongue and palate and was associated with poor feeding and weight loss. All had failed a minimum of 7 days of Nystatin ± gentian violet. All 3 cleared on Ketoconazole in 3-5 days. 2/3 had recurrence when therapy was discontinued which necessitated "prophylactic" administration of 3 mg/kg/day for 3 and 10 mos. respectively. 1 patient (8 mos.) was treated for monilial dermatitis which had failed topical therapy. The rash cleared after 10 days of treatment. All patients tolerated Ketoconazole well. All children had pre and post treatment evaluation of liver function. No adverse effects were observed. Specifically 1 infant (P2 F1) 4 mos. of age received Ketoconazole and Zidovudine concurrently for 3 mos. Pre therapy LFTs demonstrate moderate hepatocellular injury (SGOT 390, SGPT 149, Bili 7.3). LFTs progressively return to more normal values (SGOT 79, SGPT 50, Bili .7) over a 3 mos. course while on both medications. We believe Ketoconazole is a safe and effective therapy of mucocutaneous candidiasis. More information is needed about its concurrent use with Zidovudine and its use in children with evidence of hepatocellular dysfunction.

B.592

HIV-1 GP 41 ANTIGEN IN THE SERUM OF HIV INFECTED CHILDREN
Ellaurie, Maadhava; Calvelli, T. and Rubinstein, A.
Albert Einstein College of Medicine, Bronx, N.Y. U.S.A.

Objective. To detect the presence of HIV-1 gp 41 antigen in the sera of HIV-infected children and correlate with disease activity.
Methods. HIV-1 gp 41 antigen (Ag) was assayed by an immunoblot assay involving reaction with monoclonal gp 41 antibody followed by peroxidase-conjugated goat anti-mouse IgG. A positive reaction was detected by color development upon addition of substrate, and reactive samples visually graded from +1 to +4. One hundred forty-five samples from 100 patients were assayed.
Results. Eighteen of 100 (18%) patients had gp 41 Ag present in their sera. The concentration of gp 41 Ag increased in patients who had a severe clinical course and who died. The concentration of serum gp 41 paralleled the concentration of HIV proteins p17, p24 and gp 120 in the serum.
Conclusion. The detection of gp 41 antigen can be of value as an additional marker of disease activity and prognosis and could be potentially useful in monitoring patients on treatment.

B.593

WHICH AIDS PATIENTS NEED STEP DOWN CARE? A PROSPECTIVE STUDY
McCormick,Wayne C*;Inui,TS*;Deyo,RA*;deGroff,C*and Wood,R.**
*University of Washington, Seattle VA Medical Center,
**AIDS Prevention Project, Seattle, Washington, USA.

Objective.To assist in discharge planning for hospitalized AIDS patients in need of special AIDS residences with skilled nursing ("step down care"), we carried out a prospective study of 100 persons with AIDS to determine the characteristics of patients in need of such care, and to develop a discriminant rule to easily identify them at the time of admission.
Methods.We obtained demographic, medical, and social profiles of patients near the time of admission to the hospital, and concurrently interviewed their doctors, nurses, and social workers regarding appropriateness of step down care as a substitute for part of their hospital stays.
Results.Of the 100 patients(men, mean age 35 yrs), 31 were considered appropriate for step down care by their physician and nurse or social worker(or all 3). The appropriate patients were more likely to live alone(52% vs 25%), have poor(<24) MiniMental State(MMS) scores(48% vs 6%), be impaired in activities of daily living(ADLs)(77% vs 17%), or on Medicaid(65% vs 42%) (all p<.05). In multivariate analysis, three variables contributed significantly to a discriminant function: living alone, poor MMS scores, and impairment in ADLs. The function was developed on a 60% random sample of subjects, (83% correct classification, sensitivity 92%, specificity 78%, positive predictive value 73%, negative predictive value 93%, Kappa .67) and tested on the remaining 40%(sensitivity 83%, specificity 87%, Kappa .63).
Conclusion. AIDS patients appropriate for step down care differ from those who are not in several important characteristics identifiable at the time of admission. Knowledge of these factors may aid in discharge planning.

B.594

B.595

AN EARLY INTERVENTION PROGRAM FOR CHILDREN WITH HIV INFECTION.
Leonard,Noelle;Kaplan,M.;Sloan,L.;Harvell,I.;Calev,A.;Bedell,G.;et al.
SUNY Health Science Center at Brooklyn,NY,U.S.A.

OBJECTIVE. To describe a program for developmentally delayed (DD), HIV infected children and to evaluate the children's performance.
METHODS. The Infant and Child Learning Center (ICLC) provides a comprehensive educational, therapeutic and psychosocial program. Each child and caregiver attends a small class several times a week where they participate in activities which promote developmental skills and coping strategies. The staff routinely reassesses the goals for each child. In order to document developmental skills, a retrospective review was done on 23 children enrolled in the program for various lengths of time (1 mo. to 16 mos., mean 7.5 mos.)
RESULTS. Located in a hospital setting, the ICLC provides a supportive environment where families can freely express their concerns and receive immediate medical consultation and services. The table shows the results of a 3 point criterion rating scale measuring the number of children who progressed, regressed or remained the same during the time spent in program.

	Cognitive	Social/Emotional	Motor	Language
% progressed	65	52	39	52
% same	13	4	26	18
% regressed	22	44	35	30

CONCLUSION. In order to effectively service these children, an interdisciplinary, comprehensive model is necessary.

B.596

CONTROLED CLINICAL TRIAL OF ANGINLYC, CHINESE HERBAL IMMUNE ENHANCER, IN HIV SEROPOSITIVES
Sankary, Timothy, AIDS Prevention Center,
San Francisco, California, USA.

Objective. To assess the safety and efficacy of a new Chinese herbal immune enhancer developed in the People's Republic of China, which is produced from extracts of angelica, ginseng, and fructus lycium, in the treatment of early to mid-HIV infection.
Methods. 300 HIV seropositive patients with T_4 helper lymphocyte counts between 100 and 600/mm^3 and no prior HIV-related hospitalizations or ongoing treatments were randomized into double-blind treatment and placebo-controled groups. The treatment group was given two Anginlyc 50 mg capsules three times a day. Diet instructions were to avoid lobster, shrimp, crab, bamboo shoots, duck, goose and alcohol. The placebo group received similar-looking capsules and instructions. All patients were followed at biweekly visits and monthly laboratory studies including CBC, chemistry panel, T and B lymphocyte panels and p24 antigen were performed.
Results. Symptom tabulation, labs, Karnofsky score, frequency of opportunistic infections, and HIV-related hospitalizations are analysed on a monthly basis over a 6 month period and summary statistics presented with multifactorial analysis.
Conclusion. Promising non-western therapies for HIV infections deserve formal clinical trials in a randomized double-blind controled fashion to evaluate their usefulness.

B.597

EFFICACITE' ET TOLERANCE DU TRAITEMENT PAR ZIDOVUDINE (ZDV) A PATIENTS ARC OU SIDA AFFECTES.

Sette P.*;Camporiondo M.P.**;Narciso P.*;Tommini G.*;Tozzi V.*;Visco Giuseppe* et al.
U.S.L. RM/10 Hôp. "L. Spallanzani" Dep.Mal.Infect.*,& Hôp."S. Camillo"Service Virol!* Rome,Italie

OBJECTIF.Déterminer l'efficacité et la tolérance d'un traitement à long terme par ZDV donnée à deux differents dosages à patients (pt) affectés par ARC ou SIDA.

METHODES. 107 patients avec ARC (72) ou SIDA (35) ont été traités pendant 36 sem. (range 4-60) par ZDV en plein dosage (pd) (1000 mg/j) ou en demi dosage (dd) (600 mg/j) en cas d'anémie ou de granulocytopénie. Le suivie clinique, le nombre des CD4+ et l'antigenemie p 24 ont été evalués tous les mois.

RESULTATS. Aucun de nos patients avec ARC a developpé le SIDA. Entre les 34 cas de SIDA 12 sont décédés aprés un temp moyen de 9 mois sans aucune difference significative de survie entre le deux groups.(long rank test). Une augmentation des CD4 a été remarqué aprés un mois dans les 2 groups avec un retour a la valeur de base en 7 mois dans le pd group et en 5 mois dans le dd groups. Des 25 patients avec une antigenemie du 43% et 64% dans les premiers 2 mois avec un retour aux valeurs de base dans 5 mois. Dans 7 patients on a assisté à la negativation de l'antigenemie (4 à pd et 3 a dd). Tolérance:le 12,5% des patients ont montré une sévere neutropénie et le 17,5% une anémie à transfuser.

CONCLUSIONS.Le traitement par la ZDV à provoqué une transitoire amélioration des paramétres immunologiques et virologiques. Pas de difference entre les 2 group en terme de survie. Tous les patients avec un ARC n'ont pas developpé un SIDA.

B.598

B.599

RÉSULTATS PRÉLIMINAIRES DU TRAITEMENT DES MÉNINGO-ENCÉPHALITES À C. NEOFORMANS AU BURUNDI. (À PROPOS DE 50 CAS.)

FLOCH, J. J., LAROCHE, R., DEPPNER, M. D., KADENDE, P., et SAUNIÈRE, J.-F.
Faculté de médecine de Bujumbura, Burundi.

La fréquence de la cryptococcose dans le SIDA à Bujumbura dépasse celle décrite dans les autres pays (12,7% sur 322 cas de SIDA; Zaïre, 6%; É.-U., 6-10%).

Méthodologie: 50 cas de cryptococcose furent recueillis en 19 mois (juin 87-déc. 88). Les patients furent traités avec du fluconazole (FCZ), 400mg pour 2 jours, puis 200mg pour 6 semaines (A1); du fluoconazole 400mg/jour pour 6 semaines (A2); ou de l'amphotéricine B (AMB), 50mg/jour plus 5-fluorocytosine (5FC), 150mg/kg/j (B).

Résultats:

Protocole	A1 No. cas guéris Total (%)	A2 No. cas guéris Total (%)	B No. cas guéris Total (%)
Guérison:			
Sérologique	6/6 (100%)	13/15 (86,7%)	9/13 (69,2%)
Clinique	8/8 (100%)	17/17 (100%) en 24 j. (moy.)	15/17 (88%) en 26 j. (moy.)
Mycologique	4/5 (80%)	15/16 (93,6%) en 30 j. (moy.)	13/14 (92,9%) en 30 j. (moy.)
Médiane de survie	62,86 jours	86,29 jours	49,33 jours
Intolérance	1/8	1/17	6/17

Après guérison clinique et mycologique des patients, un traitement d'entretien avec FCZ 200mg/j p.o. est proposé.

Conclusion: Ce nouveau triazolé, le fluconazole, semble aussi efficace et moins toxique que AMB et 5FC.

B.600

THE TREATMENT OF INTERCURRENT PROCESSES FOR CHILDREN WITH AIDS.

MªJosé Cilleruelo,MJ.Mellado,J.Villota,G.Barreiro,M.García, P.M Fontelos.Instituto Carlos III.Serv. Pediatria.Madrid. SPAIN.

We selected 11 children,whose ages ranged from 2 months to 11 years,who suffer sympthomatic HIV infection.All of them are included in P_2 class of the CDC and present intercurrent processes:100%mucocutaneous candididiasis,100%upper respiratory infections(S.Auresus,Candida and H.Influenzae),80%malnutrition,63%gastrointestinal infections(Salmonella,Cryptosporidium,Campylobacter,E.Coli),63%hepatitis,54%sepsis(Salmonella,Pseudomona,S.Pyogenes),45%UTI(E.Coli,Proteus,Candida,Pseudomona,Klebsiella),36%pneumonias(H.Influenzae,S.Pneumoniae,Adenovirus),27% CMV + in cell culture,18%cardiac involvement,9%recurrent mucocutaneous herpes simplex.None case of tuberculous infection or pneumonia by PNC.We sistematically treat them very promptly and intensively with antibiotics.We have observed a decrease in number of bacterial infections in these patients when we use prophylaxis with antibiotics and IV gammaglobulin.We have noticed almost the disappearance of chronic mucocutaneous candidiasis with prophylaxis with Ketoconazol. The use of Cotrimoxazol prophylactically must be reserved to those children who have suffered PNC infection or to those who present other serious lung disease.Sistematic use of hipercaloric diet improves nutritional status and decreases the number of infections.

CONCLUSIONS:

1)The severity of HIV infection depends mainly on the immunosuppresive status that they present,which leads to recurrent infectious diseases.

2)An agressive treatment with antibiotics is essential for these patients with acute systemic infections and it's absolutely crucial to mintain the prophylaxis with antibiotics,antifungal agents and IV gammaglobulin to prevent infectious diseases. 3)It's important to treat the secondary condition of malnutrition with a high intake of calories to improve their nutritional status.

Toxicity and Other Drugs

B.601

ADVERSE DRUG REACTIONS IN AIDS PATIENTS.

Iribarren, J.A.; Arrizabalaga, J.; Garde, C.; Garcia, M.J.; Rodriguez-Arrondo, F.; Zuleica, O. Infectious Diseases Unit and Pharmacy Departemt. Hospital Nuestra Señora de Aránzazu. San Sebastian. Spain.

Objective: Appraisal of the incidence and severity of adverse reactions to drugs (ARD) in AIDS patients.

Methods: A prospective evaluation was made of the ARD that occurred in 112 patients who were diagnosed as AIDS in our hospital between 1985 and December 1988. The number of secondary hospital admissions, drugs responsible, need for suspending treatment and type of adverse reactions were also evaluated.

Results: There were 48 episodes of ARD in 37 (33%) of 112 patients diagnosed as AIDS. The table summarizes the number of episodes per drug and the number of suspended treatments:

DRUG	Episodes (No.)	Suspended Treatment (No.)
TMP-SMZ	13	8
AZT	11	3
Rifampicin	8	8
Pyrimethamine	5	5
Pentamidine	4	4
Amphotericin	4	2
Chloramphenicol	1	1
Ampicillin	1	1
Corticoids	1	1
Ciprofloxacin	1	0*
Vancomycin	1	1
Acyclovir	1	1

* Reinstated after desensibilization

Of the 37 patients who suffered adverse reactions, 23 were out-patients and 13 (35%) of them required hospitalization.

Conclusions: 1. ARD are common in AIDS patients. 2. Adverse reactions occur with drugs that frequently cause adverse effects (TMP-SMZ-AZT) as well as with others (ciprofloxacin, acyclovir). 3. An appreciable part of AIDS admissions are motivated by ARD. 4. Alternatives are needed for drugs like pyrimethamine, pentamidine, and, to a lesser degree, TMP-SMZ: these drugs are necessary for the treatment of opportunistic infections in AIDS patients but are highly toxic.

B.602

"CLONING AND EXPRESSION OF HIV-I AND HIV-II PROTEINS WITH DIAGNOSTIC PURPOSES"

Authors:García,J.,Novoa,L.I.,Machado,J.A.,Benitez,J.,
Padrón,G.,Herrera,L.,et al
Center of Genetic Engineering and Biotechnology
C.Habana,Cuba.

Objective:To obtain HIV-I and HIV-II viral antigen using genetic engineering techniques.

Methods:Representative regions of the genes coding for the gag 24, gp 41, gp 160 HIV-I and gp 36 HIV II proteins were inserted into a plasmid under the control of tryptophan promoter and the ligation products were transformed in E.coli.Ampicillin resistant transformants were screened by colony hibridization and those ones expresing the antigens were selected by immunoidentification with HIV positive sera.

Results:All the antigens were expressed in E.coli (15-20 o/o of the total cellular protein) as insoluble materials and prepurified by washed pellet cell procedures, followed by HPLC chromatography steps on the solubilized proteins up to purity levels higher than 90 o/o. The purified proteins were tested in an ELISA test, showing to have a high sensibility and specificity.

Conclusions:At this moment we have the major proteins for the detection of HIV-I and HIV-II antibodies in biological fluids.

B.603

HIV IMMUNOBLOT PATTERNS AND p24 ANTIGEN DETECTION IN SEQUENTIAL SERA OF HOMOGEXUAL MEN

Read, Stanley*; Major, C.**; McLaughlin, B.**; Coates, R.*; Calzavara, L.*; Fanning, M.*; et al.
University of Toronto* and Laboratory Services, Ontario Ministry of Health**, Toronto, Canada

Sequential sera, collected every 3 months over a 3 year period from 15 HIV seroconverters and 21 individuals who have developed AIDS during the study period, had antibody patterns examined by immunoblot and were tested for p24 antigen.

In the seroconverter group, one indiviual showed p24 antigen prior to the detection of HIV antibodies by immunoblot. Antibody to p24 was the first marker to appear in 6/15, antibody to p18 was the first to appear in 1 individual, while p24 and gp41 markers appeared simultaneously in 8 others.

Of the 21 persons who developed AIDS (PWAs), 20 showed persistently weak, absent or declining p24 antibody over 6 to 24 months prior to developing disease. One PWA showed an increase in p24 antibody without evidence of p24 antigen. 12 others had detectable antigen prior to and during disease.

These results provide further evidence that HIV p24 antigen may be present in seroconverters prior to the development of detectable HIV antibodies, and that declining p24 antibodies and the presence of p24 antigen are predictors of declining immunologic and clinical status.

B.605

DETECTION OF HIV ANTIGEN BY FLUOMETRIC ENZYME IMMUNOASSAY

Hiroshi Ushijima; Asano, M.; Honma, H.; Matsuno, S.; Morikawa, S.; Komatsu, T.; Kitamura, T.
AIDS Research Center, National Institute of Health, Japan

Objective. Detecting HIV antigens is more important to find HIV infection in earlier stages and to the safety of blood and blood products.
Methods. Mouse MoAbs against p24 of LAV, DEAE-Cellulose-purified anti-HIV rabbit IgG and column-purified anti-HIV human IgG from HIV carriers were used. A microplate was coated with anti-HIV human IgG and 100 μl of each sample was added. Then, biotin labelled anti-HIV antibody and β-galactosidase avidin (indirect method) or galactosidase-labelled MoAbs (direct method) were added. Finally, 4-methylumbelliferyl-galactosidase-avidin was added and the reaction was detected by Fluoro-skan II.
Results. About a few pg/ml of HIV protein was detected in the best method among them.
Conclusion. Our method is thought to be same as or slightly excceed the commersial EIA antigen detection kit in sensitivity. We are now going to examine field samples from AIDS patients, carriers and blood products.

B.606

THE EFFECT OF ZIDOVUDINE ON PLATELET COUNTS IN HIV POSITIVE INDIVIDUALS *

Montaner, Julio SG; Le, T; Gelmon, K; Fanning, M; Falutz, J; Tsoukas, C; Wells, G; O'Shaughnessy, M; Wainberg, M and Ruedy, J. Multicentre Canadian Azidothymidine Trial (MCAT).

OBJECTIVE. To characterize the nature, time course and dose dependency of zidovudine effect on platelet counts in HIV infected individuals within the Multicentre Canadian AZT Trial.
METHODS. DESIGN: Multicentre, prospective, dose range finding study. SUBJECTS: 57 HIV positive homosexual men; CDC groups IIB, III and IVC2; helper count >270 M/l and platelets ≥ 150 G/l. INTERVENTION: Following a 3 week observation period, consenting volunteers were treated with zidovudine 600 mg/day for 18 weeks, 900 mg/day for 9 weeks, 1200 mg/day for 9 weeks, no zidovudine for 6 weeks and 1200 mg/day or the highest tolerated dose for 18 weeks for a total of 60 weeks of therapy. FOLLOW-UP: Clinical and laboratory evaluations were performed at 3 weeks intervals. ANALYSIS: Analysis of variance was used to compare the mean platelet values at each zidovudine dose. Where statistical differences were found analysis of variance was performed within the dose period to characterize the timing and magnitude of the maximal change.
RESULTS. Platelet count (To) was 241 ± 44 and rapidly increased to 261 ± 50 (p<.0001) with low dose zidovudine reaching a peak by 3 weeks (3 wks vs To, p=.001). Platelet count promptly decreased to initial levels despite increasing zidovudine dose (18 wks vs To, p=.68; 900 mg vs To, p=.26; 1200 mg vs To, p=.47). Platelet count further decreased below initial values upon discontinuation of zidovudine (0 mg vs 1200 mg, p<.0001; 0 mg vs To, p<.0001) and increased once again when zidovudine was reinstated but only to the initial level (1200' mg vs 0 mg, p[illegible]002; 1200' mg vs To, p=.46). The absolute magnitude of this increment was similar to that observed initi[illegible] low dose zidovudine therapy.
CONCLUSIONS. An increase i[illegible]et count was observed in early HIV-infected individuals with initially normal platelet count treated with [illegible]ovudine. This effect was shortlasted despite continued therapy or even increasing zidovudine dose. The fact that platelet count decreased during the washout phase to increase once again upon reinstitution of therapy suggests that zidovudine may have a prolonged beneficial effect on platelet count.

B.607

ADMINISTRATION OF AEROSOLIZED PENTAMIDINE TO THE HOMELESS AIDS POPULATION IN A NON-TRADITIONAL SETTING/SHELTER

Vinitsky, S.*, McMahon, J.*, *University of Massachusetts, Boston, Massachusetts, U.S.A.

Objective. To determine the number of homeless AIDS patients living at the City of Boston's Long Island Shelter who would benefit from prophylactic treatment of aerosolized Pentamidine (A.P.) at the shelter level.
Method. The identification of the clients needing prophylaxis has been obtained from Boston City Hospital AIDS Clinic, Healthlink for the Homeless Clinic, and Long Island Shelter Nursing Clinic. The nursing protocols were adapted for application at the Shelter.
Results. Ten individuals were identified as having had one or more bouts of Pneumocystis carinii Pneumonia (P.C.P.). The high rate of HIV infection among Intravenous drug abusers and minorities within the homeless population is rapidly increasing. Delivery of A.P. prophylactically is know to decrease recurrance rates of P.C.P. Models of alternative healthcare which provide on site clinical care at shelters has demonstrated increased compliance.
Conclusion. By initiating A.P. at the Shelter, the homeless are given the opportunity for prophylaxis with minimal cost. This population who are often non-compliant would be better followed through the health care providers in the shelter with whom they have established a trusting relationship. As the disease process progresses the access to the availability of the treatment increases in importance, making the shelter the appropriate setting for administration.

B.608

INHIBITION OF SEXUAL DRIVE IN HIV CARRIERS BY MEDROXYPROGESTERONE ACETATE

DiGiovanni, Cleto * ** ***; Berlin, F.***.
*Metropolitan Psychiatric Group, Washington, DC, USA, **National Naval Medical Center, Bethesda, Maryland, USA, ***The Johns Hopkins Hospital, Baltimore, Maryland, USA.

Objective. To report further clinical experience with medroxyprogesterone acetate (MPA) as an inhibitor of sexual drive in HIV carriers.
Methods. Since our original report in 1987 of the use of MPA in one sexually promiscuous HIV carrier, we have treated 7 additional patients. All were young gay men who were seropositive for HIV antibody; all were doing well at school or work, and none had AIDS. All requested MPA because of inability to reduce high-risk sexual behavior, with resulting fear of further compromising their health and that of others. These 8 patients, treated with MPA and psychotherapy, have been followed for 3 months-2½ years
Results. Intramuscular MPA effectively inhibited sexual drive in 3-4 weeks in all patients, regardless of baseline testosterone levels. When combined with psychotherapy, it allowed patients to abstain from high-risk sexual behavior. Side effects were weight gain, hypertension (that required treatment in one patient), and boredom secondary to diminished sexual activity.
Conclusions. MPA can reduce sexual drive in HIV carriers who engage in high-risk sexual behavior. It should be reserved for persons whose behavior is paraphilic in intensity and who volunteer with informed consent. Psychotherapy is an essential component of this treatment program.

Manifestations cliniques
Clinical Manifestations

B.609 HIV-INFECTIONS AMONG i.v.- DRUGABUSERS IN THE FRG:
Prevalence-rates, differential risks and proportions of behavior change of addicts.

Kleiber, Dieter; Sozialpädagogisches Institut Berlin , Berlin (West), FRG.

Our results of a German (nearly) representative differential-epidemiological study (N= 630) to estimate the actual HIV- prevalence-rate and the relative riskiness of needle-sharing and sexual activities among i.v. drugabusers show a *much smaller percentage of infected persons than expected* (20,1% HIV-positive). A highly significant difference appeared between people living in rural vs. urban environments (Berlin 26%; North German rural area 15,7%) and in sub-populations with different sociological status. Prevalence-rates are significantly higher in i.v. drug-addicts having prison-experience (63%) compared to those who never have been inprisoned (37%). The important factors that seem to influence HIV-infection are the frequency of needle-sharing and sex-techniques especially anal intercourse and sex-techniques with high risk. From a preventive perspective the amelioration of living conditions of drugabusers (decriminalization; provision of housing opportunities, work opportunities, rehabilitation from illegality; provision of aid; self-help) cannot be stressed enough. In addition, public announcements should be visible in all places where addicts meet to shoot heroin. Acceptance of condoms must be increased and offers of support for drug-dependant prostitutes who want to leave prostitution should be provided.

B.610 INCIDENCE OF AIDS AND OTHER INFECTIONS IN SPANISH DRUG ADDICTS ANALYSIS OF 8660 CASES AFTER A DECADE OF FOLLOW-UP (1977-87)

Spanish Group for the Study of Infections in Drug Addicts.

OBJECTIVE. To study the prevalence and the characteristics of AIDS and other infections in Spanish parenteral drug addicts (PDA).
METHODS. Fifty eight Spanish hospitals reported, using a standardized form, all infectious complications in PDA who required hospital admission or hospital control as outpatients. The diagnosis of the infections were made following preestabished criteria and were the same in all participating centers. The P4F routine of the BMDP package were used for calculations.
RESULTS A total number of 8660 infectious complications in PDA have been reported from 1977 to 1987. The number of cases increased abruptly since 1984. The mean age of PDA was 24 years and the male/female ratio 3/1. Infective endocarditis was diagnosed in 637 cases (7%)(right sided or mixed endocarditis in 78%), osteomyelitis or septic arthritis in 261 (3%), skin or soft tissue infections in 416 (5%), tuberculosis in 362 (4%), tetanus in 6, self limited fever of unknown etiology in 546 (6%), acute hepatitis in 3321 (38%), chronic hepatitis in 912 (11%), AIDS in 400 (4.5%), systemic candidiasis (skin, ocular and/or chondrocostal involvement) in 671 (8%), malaria in 8 and "other infections" in 1120 (13%). The overall mortality was 3.5%. AIDS in PDA appeared in our country in 1984 and increased abruptly in 1987. Extrapulmonary or disseminated tuberculosis (27%), esophageal candidiasis (24%), Pneumocystis carinii pneumonia (18%) and C.N.S. toxoplasmosis (11.5%) were the most common diagnostic presentations. The cumulative mortality of AIDS cases was 36%.
CONCLUSIONS. Infectious complications in PDA have became an emerging and growing problem in Spain since 1984 and AIDS increased abruptly in 1987.

B.611 RAPID PROGRESSION OF ORGANIC DELUSIONAL SYNDROME TO DEMENTIA IN AIDS

Holmes, Valerie F; State University of New York at Stony Brook; Stony Brook, New York, USA

Objective. To clinically assess the course of Organic Delusional Syndrome in patients with AIDS.
Methods. Hospitalized AIDS patients referred to the Stony Brook University Hospital Psychiatric Consultation Service were assessed by a board certified psychiatrist utilizing medical chart review and semi-structured interview. Diagnoses were made using DSM-III-R criteria.
Results. Case 1: 39 y.o. male IVDA with AIDS on methadone maintenance experienced an acute onset of delusional parasitosis. He responded well to pimozide, but developed akathisia and cogwheel rigidity. These resolved with the addition of diazepam and discontinuation of pimozide. Within 2 months he became demented. Case 2: 45 y.o. female former IVDA with AIDS experienced an acute onset of paranoid delusions. She responded well to haloperidol, but developed acute dystonia. This resolved with benztropine and discontinuation of haloperidol. Within 1 month she became demented. She died 3 months later.
Conclusion. It is known that some organic mental disorders can progress to dementia and even death. These cases: (1) confirm the increased frequency and severity of adverse reactions to conventional pharmacotherapies noted by other investigators; (2) suggest that the presence of an organic mental disorder, specifically Organic Delusional Syndrome, may be predictive of the dementia process, perhaps hastening its onset or making its course more fulminant; and (3) raise the question of increased vulnerability to organic mental disorders in HIV-infected IVDAs.

B.612 CLINICAL CHARACTERISATION OF HIV2 DISEASE IN WEST AFRICA

TUMANI CORRAH EGBOGA A.A. WILIKINS A.B.GAYE I, WHITTLE H AND GREENWOOD B.
MEDICAL RESEARCH COUNCIL, FAJARA, THE GAMBIA.

OBJECTIVES: Particular attention is paid to the pattern of secondary infections in patients with HIV2 disease.
METHODES:All cases suspectical of having AIDS, AIDS selected complex on progressive generalised lumphodepathy were enclosed in the study. Seaological diagnosis was made by. Hardard methods priorier tested in our laboratory. Primary sceening users wellocozyme 1 and 2 tests. Positive HIV1 is confirmed using seaodiagnostic gel agglutimation test (Fujinibio) and positive HIV2 by Elania II. When concordant test for me or both Viauses are made.
RESULTS: At the total number of HIV seropositives studied 26% ARE, 2% PGL, 5% tuberculosis. The main clinical manifestations of HIV2 disease include wight loss 100%, pynexia 93% oral thoush 71, chronic diarrhoeas 64%, chronic cough 50% and neurologicaloynitons 43%.
HIV2 exerce mortality and morbidity similar to HIV1. There is evidence of vertical transmission.
CONCLUSIONS:

B.613 HIV INFECTION - IMMUNOLOGICAL STUDIES IN BULGARIA

Plotchev, Kamen; Taskov,H.; Vasilev, Tch.; Ognjanov, M.; Dikov, I.; Doganov, B.
Institute for Infectious Diseases, Sofia, Bulgaria.

For a period of three years we have been studiing the immunological status of 50 men infected with HIV /proved by ELISA and western blot/. 3 of them have AIDS, 7 slight clinical disturbances and 40 are carriers of HIV.

22 out of these 50 men with HIV infection have signs of disfunction in the immune system: impaired cell-mediated immunity, changes in the T4/T8 ratio and negative skin multitest. In this group 3 men have AIDS, 7 - slight clinical disturbances and 12 are HIV carriers, the latter having no signs of opportunistic infections or neoplasms associated with AIDS.

B.614 OBSERVATIONS CLINIQUES SUR H I V INFECTION EN BULGARIE

DIKOV I.,DOUHOVNIKOVA T.,CHARAKCHIEVA R., DJBLEKOVA J.,KONCHEVA R.,PLOTCHEV K. et al.
Clinique des Maladies Infectieuses, SOFIA,BULGARIE
''Hopital Regional ,BOURGAS,BULGARIE

Pendant le period de 01.01.1986 jousqu'a 31.12.1988 ont ete observe 33 persons de nationalite bulgare avec une serologie positive pour HIV / par ELISA et WesternBlot /. Dápres l'observation dynamique clinique,laboratoire et immunologique on distingue: un malade avec tableau clinique du SIDA et infections opportunistiques et Sarcoma Kaposhi generalisee, qui est decede apres 13 mois d'evolution, un malade avec polyneuropathie recidivante isolee, 9 persons avec infections indicatrices / candidiases,dermatoses seborrheiques, campylobacterioses et otr./. 7 persons avec signes laboratoires / VS eleve, leucopenie et lymphopenie / sans signes cliniques.

B.615

PULMONARY HEMORRHAGE IN PNEUMONITIS OF HIV-INFECTED PATIENTS

Bréchot, Jeanne-Marie*; Doré, M.F.*; Capron, F.**; Waked, M.*; Rochemaure, J.*
*Department of Pneumology; ** Laboratory of Anatomy and Pathologic Cytology; Hôtel Dieu; Paris; France.

Objective. Study the frequency of pulmonary hemorrhage (PH) in pneumonitis of HIV-infected patients by scoring alveolar macrophage hemosiderin load as described by Golde (Golde's score GS).
Results. On 16 of the consecutive 134 bronchoalveolar lavage (BAL), PH was diagnosed with a GS greater than 100 (mean value= 125) and was occult in 14 cases. In one, a severe thrombocytopenia was concomittant (13.10^9/ml).
PH was associated with bacterial pneumonitis (2 cases), opportunistic pneumonitis (11 cases) and bronchopulmonary Kaposi sarcoma (3 cases).
A fatal outcome occured in 2 cases (GS: 117 and 126). In 2 patients with an initial GS of 118 and 113, GS of control BAL performed 1 and 3 months later were respectively 36 and 0. In 3 patients, GS remained greater than 100 in a delay of 1 to 10 months, associated with persistent pulmonary multiple opportunistic infections.
Conclusion. Hemosiderin score is a semi-quantitative approach for the diagnosis of PH. However, in our serie, this diagnosis was always associated with either bacterial or opportunistic infections or Kaposi sarcoma.

B.616

HEMOPTYSIS COMPLICATING PNEUMOCYSTIS CARINII PNEUMONIA

Vaidya, K.P. and Lomvardias, S.
Dept. of Pathology, Woodhull Medical & Mental Health Center, Brooklyn, New York USA

Objective: To describe pulmonary destruction with hemorrhage associated with Pneumocystis carinii (PC) pneumonia.

Case Report. A 54 year old Hispanic female intravenous drug addict presented with hemoptysis of two days duration, fever, chills and productive cough.She had cachexia, tachypnea, generalized lymphadenopathy, oral candidiasis and bibasilar rales. Radiograph revealed interstitial infiltrates in the right upper and left lower lobes, which subsequently became diffuse, and strongly suggestive of PC pneumonia. Bronchoscopic examination detected active bleeding from the right upper lobe bronchus, anterior segment. Bleeding persisted for five days. The patient's condition deteriorated to respiratory distress, right side pneumothorax, and she expired ten days after admission. At autopsy all lobes showed diffuse hyaline membrane formation, masses of PC in the alveoli and aggregates of foamy macrophages. In addition, the right upper lobe contained a few cavitary lesions (0.3 to 1.0 cm) lined by granulation tissue, small remnants of bronchiolar epithelium, and dilated engorged blood vessels close to the surface. Few PC organisms were demonstrated within the cavities but no other infectious agents were noted in spite of prolonged search with various special stains. It is noteworthy that the patient had survived an episode of PC pneumonia seven months earlier.

Conclusion: Hemoptysis in an AIDS patient may be a sign of PC pneumonia.

Diagnostic
Diagnosis

B.617

ETUDE DE LA SPECIFICITE DES ANTICORPS DETECTES CHEZ DES SUJETS EN COURS DE SEROCONVERSION A L'AIDE DE PROTEINES RECOMBINANTES

GADELLE S., CRABBE C., LESIEUR C., DELAGNEAU Jean François,
Diagnostics Pasteur, Marnes (France)

Objectif : Montrer la prédominance d'anticorps dirigés préférentiellement contre la protéine interne P25 ou contre la glycoprotéine d'enveloppe gp160 lors de séroconversions.
Méthodes : Les prélèvements séquentiels de sujets en cours de séroconversions ont été analysés par Western Blot et par un test ELISA fondé sur l'utilisation de protéines recombinantes (TRANSGENE, France). Les premiers prélèvements (n=8) ont été testés par un ELISA indirect gp160 (exprimée dans les cellules BHK21 infectées par un virus recombinant de la vaccine),par un ELISA indirect p25 (exprimée sous forme native dans une souche E.Coli transfectée) et par un ELISA mixte gp160/p25.

Résultats : ELISA	P25	GP	P25 + GP
DO valeur seuil	0.295	0.398	0.258
Nombre de positifs (n=8)	7	7	8
Nombre de négatifs	1	1	0
	(DO:0,133)	(DO:0,317)	

CONCLUSION : La majorité des séroconversions présentent des anticorps dirigés préférentiellement contre la gp160. Cependant la prévalence d'anticorps anti p25 chez certains sujets confirme l'intérêt de l'utilisation des deux protéines p25 et gp160 dans les tests de seconde génération afin de garantir le dépistage de toutes les séroconversions.

B.618

EVALUATION OF AN ULTRASENSITIVE ELISA FOR SPECIFIC DETECTION OF ANTI HIV 1

Brust, Stefan; Krupka, U.; Behringwerke AG, 3550 Marburg, FRG

Objective: To evaluated an improved competitive ELISA for the detection of antibodies against HIV 1.
Methods: 100 µl undiluted specimens are pipetted to 25 µl diluent buffer in each well of microtitration plates coated with cell culture propagated HIV 1 antigens. The first incubation step over 60 min at 37 °C is directly followed by addition of ready to use conjugate (peroxidase labelled human Anti HIV 1). After 30 min (37 °C) and 5 washings H_2O_2 and the chromogen TMB is added. The enzymatic reaction is stopped after 30 min (RT) with 0,5 N H_2SO_4 and readings are made at 450 nm. The cut off value is defined as 50 % of the negative control.
Results: The results on screening 643 Anti HIV 1 samples refer to a sensitivity of 100 % with clear cut positive inhibited O.D. values. The detection limit of ^{R}Enzygnost-Anti-HIV 1 ultra was found to exceed that of western blot analysis by factor 8. A panel of 13 sera derived from early stages of HIV 1 infections were found positive, even those, which were negative in the Western blot and in commercial 2nd generation ELISAs. A specificity of 99,86 % (retest 99,95 %) can be deduced from testing 3000 paired serum and plasma specimens.
Conclusions: In view of the fact, that Anti HIV 2-sera were found negative or weak positive, this ELISA in combination with a specific Anti HIV 2-test will help discriminating HIV infections.

B.619

EFFICACY OF ABBOTT RECOMBINANT HIV-1/HIV-2 EIA FOR EARLY DETECTION OF HIV-2 AND/OR HIV-1 SEROCONVERSION

F. FERCHAL, F. AGBALIKA, P. HONDERLICK, V. BARATEAU, Y. PEROL
Laboratoire de Bactériologie-Virologie, Hôpital St-Louis, Paris, France.

The greatest difficulty in HIV diagnosis in Europe is to have at one's disposal an Elisa test sensitive enough to detect low levels of HIV-2 as well as HIV-1 antibodies. We determined the performance characteristics of Abbott Recombinant HIV-1/HIV-2 EIA by studying sequential sera from one HIV-2 and seven HIV-1 seroconversions.
HIV-2 seroconversion Results

	ELAVIA I*	ELAVIA II*	ELAVIA I + II*	Ab Rec I	Ab Rec I + II	RIPA HIV 2			
						gp140	p36	p26	p16
June 20, 1986	0.02	0.36	0.36	0.34	0.62	-	-	-	-
June 21	0	0.28	0.28	0.28	0.61	-	-	-	-
June 23	0.42	0	0.85	0.82	1.52	-	-	-	-
July 7	0.20	1.7	1.48	0.77	1.23	+	-	-	-

Aug. 11	1.2	≥ 6	≥ 6	0.84	1.97	++	+	+++	++
Aug. 28	2.43	≥ 6	≥ 6	1.04	2.42	++	+	+++	++
Jan. 21, 1987	2	≥ 6	N.D.	1.14	5.42	N. D.			

* Elavia I, Elavia II, Rapid Elavia I et II : Diagnostics Pasteur

All HIV-2 confirmed positive sera of our panel (n = 21) were detected by Abbott Rec. HIV-1/HIV-2 EIA.
HIV-1 seroconversions results : the seven cases of our panel HIV-1 seroconversions were documented at the same time by Abbott Rec. HIV-1/HIV-2 EIA and Rec. HIV-1 and in five of these cases 13 to 27 days before the western blot showed any specific band.
We can conclude that in our hands Abbott Rec. HIV-1/HIV-2 recognized all HIV-2 positive sera and low level of initial antibody production associated with HIV-2 or HIV-1 primary infection.

B.620

DETECTION OF SERUM ANTIBODIES AGAINST ONLY THE GAG PROTEINS: A LATENT OR AN ABORTIVE INFECTION WITH AN HIV VARIANT?

M. Theodoropoulou, N. Malliarakis, E. Spanakis, E. Malliaraki-Pinetidou, V. Georgoulias AIDS Reference Center of Crete, Venizelion Hospital, Iraklion, Greece and School of Medicine, University of Crete, 41709 Irakhon, Greece

Objective: To determine whether heterosexuals displaying antibodies against only the gag proteins are realy HIV-infected
Methods: Peripheral blood lymphocytes (PBL) were co-cultured with the HIV- permissive CEM leukemic cell line and virus replication was evaluated by the reverse transcriptase activity (RT) and the p24 antigen of the culture supernatant (SN). Moreover, the ultra centrifecgated pellet of SN was tested for HIV by an RNA \cDNA dot blot using specific cDNA probes. The membrane expression of p24 protein on PBL was evaluated by immunofluorescence using moABs. Intergrated viral sequences were detected by Southern blot.
Results: PBL of 7\9 subjects expressed the p24 molecule (range 3-16%) whereas p24 protein was detected on adherent cell but not PBL in an additional subject. Gp120 was also expressed on PBL in 6\9 and on the adherent cells in the above mentioned subject. Low levels of RT activity were detected in the SN of 2\5 subjects whereas p24 Ag could be revealed in 2 additional cases. RNA\cDNA dot blots of the ultra centrifugeted pellet revealed a positive reaction with both gag and env HIV-1 cDNAs in 6\16 cases. Finally, Southern analysis of DNA from adherent but not unfractionated PBL revealed HIV-related sequences in 1\3 tested cases.
Conclusions: These findings indicate that some of the heterosexuals displaying antibodies against only the gag proteins present a latent or an abortive infection with an HIV-related virus.

B.621

SIMULTANEOUS THREE COLOR DETECTION OF HUMAN T CELLS (CD2, CD4 AND CD8) BY FLOW CYTOMETRY

Bergeron, Michele; Mandy, F. and O'Shaughnessy, V.M. Bureau of Laboratories and Research Services, Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada.

Objective. To obtain rapid results with T cells markers utilizing 0.1 mL of blood. By choosing some optical filter and dye configurations on a flow cytometer that has 3 color-photomultiplier tubes (PMTs).

Method. A Coulter EPICS Profile (PROFILE) was configured with 3 log. fluorescence PMTs. The optical bench had three interchangeable filter blocks, each block held 5 filters. For this project we chose allophycocyathin (APC/red/FL3), phycoerythin (PE/orange/FL2) and fluorescein (FITC/green/FL1) as colors because all 3 dyes absorb light at 488nm. FL1 with the green PMT was nearest to the laser. The FL2 and FL3 PMTs received the PE and FITC signals respectively. The monoclonal antibodies and dyes were matched empirically. Some electronic color compensation was required.

Results. Starting with filter block 1 the dichroic filters were 488, 550LP, and 610SP nm respectively. Again in the same order the barrier filters for the three PMT's were 530 DF 30, 660 DF 35 and 580 DF 20 respectively.

Conclusion. Utilizing only 0.1 mL of blood with a PROFILE instrument three T cell markers were detected simultaneously.

B.622

Anti-HIV test of third generation
(Evaluation of sensitivity by HIV seroconversion)

H.I. Joller-Jemelka*, P.W. Joller**, Parkhede U.***
* University Hospital Zurich, Switzerland; ** ANAWA Laboratories, Wangen, Switzerland; *** Pharmacia Diagnostics AB, Uppsala, Sweden.

Sera were available of 15 individuals before anti-HIV screening test became positive (seroconversion). HIV antigen (p24) became detectable before seroconversion in all 15 individuals. As early as HIV-Ag, IgM anti-HIV also became detectable as measured by Western Blot but these antibodies persisted longer. In 10 individuals anti-HIV as measured by a new anti-HIV test system (based on synthetic peptides, directed towards the transmembrane associated anti-HIV 1 and anti-HIV 2 respectively and recombinant produced p24) also became positive before seroconversion. IgM anti-HIV and HIV-Ag are of help in early diagnosis of HIV infection but cannot be used as screening tests. For anti-HIV screening only tests of second or third generation should be used.

B.623

DIAGNOSIS OF HIV-1 INFECTION IN AFRICAN COUPLES: COMPARISON OF SEROLOGY AND PCR.

Vaira, Dolores; Sondag-Thull, D.; François-Gérard, Ch.; Doppagne, A. and Rentier, B.
AIDS Reference Laboratory, Université de Liège, Belgium.

Objective. Search for the rate of HIV-1 contamination among seronegative sexual partners of seropositive individuals.

Methods. Classical serological methods (EIA, WB) and PCR.

Series. 36 heterosexual couples from central Africa, accounting for a total of 73 persons:
13/37 seropositive women,
23/36 seropositive men.
All couples were serologically discordant, i.e. one partner was seropositive.

Results. Detection of provirus by PCR in peripheral mononuclear cells from seronegative partners was distributed as follows:

seronegative	women	men
PCR positive	15	9
PCR negative	7	3
not tested	2	1
TOTAL	24	13

Conclusion. In such a population, particularly at risk of HIV contamination, the rate of false negative serological diagnosis reached 70%

B.624

PROPOSAL FOR THE ANTI HIV TESTING PROTOCOL

Krupka, Udo; Brust, St.; Behringwerke AG, 3550 Marburg, FRG

Objective: To propose a strategy for testing Anti HIV. In view of new assays for the simultaneous detection of Anti HIV-1 and -2 a second ELISA-level might be useful for the differentiation and confirmation of positive or equivocal results obtained in the initial level of combined screening.

Methods: The peptide based indirect test ^{R}Enzygnost-Anti-HIV 1 + 2 was used for the initial testing (4 env-peptides of HIV 1 and HIV 2; 50 µl undiluted specimen; total assay time 90 min.). For testing on Anti HIV 1 and Anti HIV 2 two highly sensitive and specific assays were employed. ^{R}Enzygnost-Anti-HIV 1 ultra is a sequential saturation assay using a modified competitive format and cell culture propagated viral antigens. ^{R}Enzygnost-Anti-HIV 2 is based on the indirect principle and a synthetic peptide corresponding to gp41 of HIV 2.

Results:

n	positive by combined screening RE.-Anti-HIV 1+2	positive with ^{R}E.-Anti-HIV 1 ultra	positive with ^{R}E.-Anti-HIV 2	western blot A.HIV 1	western blot A.HIV 2
182 Anti-HIV 1	182	182	11 borderline pos.	182	23
39 Anti-HIV 2	39	13 borderline pos.	39	19	39

Conclusions: These findings indicate both second-level ELISAs best suited for the differentiation and confirmation of initially positive results by testing with a combination assay. This procedure will help reducing the cost- and time-consuming western blot analysis.

B.625

HIV IgG ANTIBODY AT THE AGE OF 12 OR 18 MONTHS BUT NOT HIV IgM ANTIBODY AT BIRTH OR AGE 3 MONTHS CORRELATES WITH CLINICAL EVIDENCE OF PERINATALLY-ACQUIRED HIV INFECTION(PI).

Ryder, Robert*/**; Nsa, W.*; Francis, H.*/***; Hassig, S.*; Behets, F.*; Vercauteren, G.****; Piot, P.****; Quinn, T.***; *Projet SIDA, Kinshasa, Zaire; **CDC, Atlanta, GA; ***NIH, Bethesda, MD; ****ITM, Antwerp, Belgium.

Objectives. To determine the correlations between detection of HIV IgM antibody (cord blood, age 3 mos.) and HIV IgG antibody (12 mos., 18 mos.) and the development of clinical evidence of PI.

Methods. Two groups of children have been followed since birth. Group I children had 373 children with HIV(+) mothers. Group II consisted of 100 children born to HIV(-) mothers. Blood collected at birth(IgM-0) and at age 3 months(IgM-3) from both groups of children was tested for HIV IgM antibody by Western blot (DuPont). Blood collected from the same children at age 12(IgG-12) and 18(IgG-18) months was tested for IgG by ELISA (Welcozyme) and confirmed by IgG Western blot (DuPont). Children who developed clinical signs/symptoms compatible with the provisional WHO case-definition for pediatric AIDS were defined as having AIDS. Pearson's correlation coefficients(CC) were calculated.

Results. Pearson's CC for various diagnostic criteria for PI.

	Clinical AIDS	IgM-0	IgM-3	IgG12	IgG18
IgM-0	.0568	-	-	-	-
IgM-3	.0588	.3867**	.3867**	-	-
IgG-12	.3581**	.0482	.1172*	-	-
IgG-18	.2966**	.0489	.1176*	1.00**	-

(P value for Pearson's CC; *P<.05; **P<.01)

All 100 GpII children were persistently negative for all serologic markers.

Conclusions. Use of IgM Western blots to diagnose PI was not useful. A high correlation did exist between development of clinical AIDS and a positive IgG-12 and IgG-18. The CC of 1.0 between IgG-12 and IgG-18 suggests that in most infants detection of IgG-12 indicates PI and not residual maternal antibodies.

B.626

AN IN VITRO EIAV RT MODEL FOR SCREENING OF ANTI-HIV AGENTS

§Pei-zhen Tao, §Xing-quan Zhang, §§Ke-jiu Quan, §Institute of Medicinal Biotechnology, CAMS, Beijing, P.R. CHINA, §§Beijing Institute of Military Horses, Beijing. P.R. CHINA

Objective. To establish an in vitro model for HIV using reverse transcriptase (RT) assay of equine infectious anemia virus (EIAV).

Methods. Virus was concentrated from tissue cultures and disruped. EIAV RT assay was directed by (rA)n.$(dT)_{12-18}$ with normal substrate dTTP (specific activity,5070cpm/pmol). Several 5′-triphosphates of 5-substituted 2′-deoxy-uridine (-Et, -nPr, -nPre, -iPre, -CE) including AZTTP and FLTTP were synthesised chemically.

Results. The IC$_{50s}$ of 5′-triphosphates of nucleoside derivatives were estimated against EIAV RT with decreasing potent order : FLTTP > AZTTP > PrearaUTP > PFA(phosphonoformic acid) > PredUTP = CEdUTP > EtdUTP > nPrdUTP >> PAA(phosphonoacetic acid). PrearaUTP was a competitive inhibitor and PFA was a non-competitive inhibitor of EIAV RT with respect to dTTP respectively. The K_m value of EIAV RT for dTTP was 2.0uM. The main properties of EIAV RT were also investigated.

Conclusion. The sensitivities of EIAV RT towards the inhibitors and profile of enzyme kinetic study were corresponding to HIV RT. Thus the EIAV RT in vitro model is suitable for anti-HIV agent screening especially easy handing.

B.627

CORRELATION OF SEXUAL BEHAVIOUR AND ANTISPERM ANTIBODIES IN HOMOSEXUAL MEN

Mulhall, Brian P.*, Carter, L*, Clark,S*, Harrison, L*, Fieldhouse, E.**,Short, R.**
*Burnet Clinical Research Unit, Walter & Eliza Hall Institute and AIDS Service,
Royal Melbourne Hospital, Australia; **Monash University, Melbourne, Australia

Objective: To detect antisperm antibodies in the serum of homosexual men and their relation to sexual practices, with a view to the development of a screening test that would act as a epidemiological marker for the practice of anal sex.
Methods. Using information obtained from a questionnaire, 60 homosexual volunteers from a previously enrolled cohort were grouped according to life-style over the previous six months viz. group 1 - oral intercourse only (n=13), group 2 - oral and anal intercourse (n=39), group 3 - anal intercourse only (n =2), group 4 - celibate (n=6). Test sera were screened for antisperm antibodies using an indirect immunobead assay; in addition all sera were screened for anti-HIV antibodies, and lymphocyte subsets were quantitated.
Results. Six of 60 (10%) sera were positive for antibodies to sperm; all were from groups 2 and 3. None of the recipients of oral intercourse alone had antisperm antibodies. Thirty subjects had antibodies to HIV; clinically they were all asymptomatic. Of the six antisperm antibody positive sera, two were positive and four negative for antibodies to HIV. There was no difference in lymphocyte subsets between the HIV seropositive and seronegative groups or between antisperm antibody positive and negative subjects.
Conclusions. These findings suggest a role for antisperm antibodies as a marker of receptive anal intercourse. Further studies are needed to test this possibility more fully.

B.628

VALUE OF Ig CLASS AND IgG SUBCLASS DETECTION IN THE SERUM AND CSF AS A PRONOSTIC MEANS IN HIV INFECTED PATIENTS.

Catherine TAMALET,S.ROUSSEAU,D.RAOULT,H.GALLAIS,J.ROMETTE, J.TAMALET.Hôpital de la Timone,Marseille,FRANCE.

OBJECTIVE : To estimate the pronostic value of the IgA,IgM, and IgG subclass specific antibodies in the sera and CSF of HIV infected patients.
METHODS : Sera and CSF samples were obtained from 15 HIV infected patients (7 AIDS,4 ARC,4 Asymptomatic).Ig class and IgG subclass specific antibodies were identified by western blot using monoclonal antibodies.The intrathecal synthesis (ITS) was investigated.P24 HIV antigen and HIV isolation were carried out. A physical examination of the patients was performed 12 months later.
RESULTS : We found an ITS in most cases.In all patients IgG1 was the preeminent subclass,followed by IgG3,then IgG2 and IgG4.Antibodies to env proteins were mainly IgG1.IgG3 developed to gag and sometimes to env and pol proteins. In contrast to IgG1 response to env proteins in sera and CSF of the 3 groups of patients, a restriction of the other IgG subclasses was observed in AIDS patients.The CSF IgG/Serum IgG antibody ratio was approximately 1 to 3. Sera anti p24 IgM were detected in 2 symptomless patients.Sera and CSF specific IgA were found in 4 symptomless, 1 ARC and 1 AIDS patients.Twelve months later, 5 of the 7 AIDS patients were dead;one of the ARC patients had AIDS.The other patients were in the same clinical condition.
CONCLUSION : In a few cases of AIDS, ARC and symptomless patients, our data suggest that IgG subclass determination in sera and CSF were not significantly correlated with clinical stages of infection and may not be of pronostic value.

B.629

DEPISTAGE SIMULTANE DES INFECTIONS VIH1 ET VIH2 EN FRANCE A L'AIDE D'UN TEST MIXTE

COT Marie Camille (1), GADELLE S. (1), BRUN-VEZINET F. (2), COUROUCE A.M., (3), FOUCAULT C. (4), JANOT C. (5)
(1) Diagnostics Pasteur, Marnes, France
(1) Hôpital BICHAT, Paris, France
(3) Institut National de Transfusion Sanguine, France
(4) CRTS La Pitié Salpêtrière, Paris, France
(5) CRTS Nancy, France

Objectif : Vérifier la capacité d'un test mixte à détecter les anticorps contenus dans le sérum de sujets infectés par les virus VIH1 ou VIH2 et à être utilisé en dépistage de routine.
Matériel et Méthodes : Le test RAPID'ELAVIA MIXT (REM, Diagnostics Pasteur) est un test ELISA en microplaque utilisant sur une simple cupule un mélange des virus entiers VIH1 et VIH2. Ce test a été modifié et la nouvelle formule a été utilisée en France dans 2 Centres de Transfusion Sanguine (CRTS,Nancy; CRTS, La Pitié Salpêtrière, Paris), à l'Institut National de Transfusion Sanguine, et à l'Hôpital Bichat à Paris. Ont été testés 2870 sérums de donneurs de sang, 108 sujets infectés par le virus VIH1 dont 16 sujets en cours de séroconversion et 115 sujets infectés par le virus VIH2.
Résultats

SERUM	Resultats REM	Performances
2870 donneurs	2853 négatifs	spécificité:1ère intention : 95,41 % 2ème intention : 99,62 %
92 VIH1 positifs	92 positifs	Sensibilité : 100 %
16 séroconversions VIH1	16 positifs	
115 VIH2 positifs	115 positifs	

Conclusion : Le test REM utilisant la totalité des épitopes des deux virus présente une sensibilité permettant la surveillance simultanée de l'épidémiologie VIH1 et VIH2. Sa spécificité en Centre de Transfusion en fait un test tout à fait utilisable en routine.

B.630

TAX: IT'S ROLE IN THE DIAGNOSIS OF HTLV I INFECTION

Cerney, M.*; Monplaisir, N.**; Nguyen, M*; Osame, M.***; Sonoda, S.***; and Lee, Helen*
*Abbott Laboratories, North Chicago, IL, 60064, USA **Centre de Transfusion Sanguine, Fort de France, Martinique, ***Kagoshima University, Kagoshima, Japan

OBJECTIVE. To evaluate the diagnostic potential of antibody to the HTLV I tax protein (p40X).
METHODS. Blood was collected from 619 Martinique donors, 25 IV drug abusers in the U.S., 33 TSP/HAM and 25 ATL patients. Samples were screened by two types of EIA; the first using HTLV I virus lysate as the capture antigen, the second using a tax recombinant protein. All samples were also tested by Western blot and SDS-PAGE RIPA.

RESULTS.

EIA	MARTINIQUE		IVDA		TSP/HAM		ATL	
	40X+	40X-	40X+	40X-	40X+	40X-	40X+	40X-
HTLV I +	10	15	2	20	32	0	8	13
HTLV I -	1*	593	0	3	0	1	0	4

*Western blot and RIPA negative

CONCLUSIONS. Greater than 95% of TSP/HAM, but only 35% of ATL patients tested, developed antibodies to 40X. Data from endemic blood donors and IVDA suggest that antibody to 40X does not seem to provide an additional diagnostic role in HTLV I infection.

B.631

SEROPREVALENCE OF HTLV-I AND HIV-1 IN ADULT HEMATOLOGIC ONCOLOGY PATIENTS

Fischer, Harald E.*; Lichtiger, B*; Reuben, J*
*University of Texas, M.D. Anderson Cancer Center, Houston, TX, USA.

Objective. To determine the seroprevalence of HTLV-I and HIV-1 in cancer patients with hematologic malignancies.
Methods. Sera from patients with hematologic malignancies were assayed by ELISA for the presence of antibodies to both HTLV-I and HIV-1 using the FDA-approved, commercially available kits. Patient categories included acute and chronic T and non-T lymphoid and myeloid leukemias, Hodgkin's and non-Hodgkin's lymphomas, as well as preleukemic states. Volunteer normal blood donors served as cohorts.
Results. A positive reaction was scored according to manufacturer's recommendations

Group	N	HIV-1 Reactive	HTLV-I Reactive	
			Initial	Repeat
Patients	272	3	9	NA
Normal	2050	0	29	11

Conclusion. The seroprevalence rates in hematologic oncology patients for HIV-1 and HLTV-I are 1.1% and 3.3%, respectively. The rate for HTLV-I is more than double that seen in normal blood donors.

B.632

B.633

NATURAL HISTORY OF HTLV-I INFECTION

Nobuyoshi Tachibana*, K. Tsuda*, M. Yoshida**, M. Essex***, N. Mueller***
*Miyazaki Medical School, Miyazaki, Japan, **Cancer Institute, Tokyo, Japan, ***Harvard School of Public Health, Boston

Objective: To describe the natural history of HTLV-I infection within an endemic area of Kyushu, Japan.

Methods: A population based cohort established of approximately 1687 adult residents of two villages, of whom 505 are HTLV-I positive. HTLV-I antibody titer was determined by PA and proviral DNA in carriers lymphocytes was investigated.

Results: Antibody titers of sixty percent of carriers ranged between 512 and 2048. Of 78 consecutively determined for four years, 63 kept the same titer. During this period 7 seroconversions have been observed.
No ATL case has been observed. However, among 40 carriers tested for proviral DNA in the lymphocytes, a sample from a healthy woman presented the pattern of monoclonal integration. Thirty-six percent of her lymphocyte was Tac positive but the abnormal lymphocyte count was less than one percent, suggesting to be in the preleukemic stage.

Conclusions: Continuing the surveillance on carriers in association with preleukemic stage is important in understanding of natural history and may provide a lead to elucidate the factors in leukemogenesis of the virus.

B.635

DUAL ASSAY OF HTLV-I AND HIV-1 ANTIBODY USING ANTI-FC EIA WITH RECOMBINANT HIV-1 AND HTLV-I ANTIGENS.

Chung-ho Hung, L. Tang, W. Zeigler, R.M. Thorn, G.A. Beltz, D.J. Marciani, et al. *Cambridge BioScience Corporation, Worcester, MA, USA.*

Objective. To develop a recombinant antigen immunoassay (EIA) that has the capacity to detect both HIV-1 and HTLV-I antibodies in human sera. Methods. Affinity-purified goat anti-human IgG Fc and anti-human IgM Fc were coated on microtiter plates to capture human antibodies from test serum. Virus specific antibodies were then detected by peroxidase-labeled recombinant HIV-1 and HTLV-I antigens using individual antigen conjugates or mixtures. 200 HIV-1 positives, 80 HTLV-I positives, 2 HIV-1 and HTLV-1 coinfections, 1027 HIV-1 negative blood donors, and a seroconversion panel were evaluated. In addition, dilutions of positives were also tested. Results. The assay identified all the positive samples tested using individual antigen conjugates. No significant change in positive signals were observed when both antigen conjugates were used. The HIV-1 and HTLV-I coinfected samples produced additive signals. This assay could detect HIV antibody as early or earlier than current viral lysate EIA's using an HIV-1 seroconversion panel. Conclusion. In this EIA test, each antigen conjugate reacted with their respective target antibodies independently. This EIA system can be used to detect both HIV-1 and HTLV-I antibodies in one test without significant loss of sensitivity for antibodies to either virus.

B.637

FOCUS OF HTLV-1 ASSOCIATED TROPICAL SPASTIC PARAPARESIS IN EQUATEUR, ZAIRE

Kazadi, K.*, Desmyter, Jan**, Goubau, P.**, Carton, H.**.
* University Hospital, Kinshasa, Zaire; ** Rega Institute and University Hospitals, Leuven, Belgium.

Objective. To present the first focus of HTLV-1 associated tropical spastic paraparesis (TSP) in Africa. Only 5 sporadic cases are known in Africans, although Africa has the largest world reservoir of HTLV-1.
Methods. Search among chronic paraparesis patients from Lisala, population 50,000, Equateur Province, Zaire, by HC and KK. Elisas and immunoblots by PG and JD.
Results. 39 cases (11 men, 28 women) of HTLV-1 associated TSP were identified : 21 by direct examination, and 18 in close blood relatives of 10 of the above, as derived from typical history and confirmed in all 4 examined. 7 mothers but no fathers or spouses of TSP patients had TSP; 3 familial cases were in paternal relatives. Half of the patients were Mundunga who represent 10 % of the population (p<0.01). Presentation, history, serology and spinal fluid findings were as seen elsewhere.
50 % of healthy close relatives had anti-HTLV-1. Patients were anti-HIV negative.
Conclusions. This first African focus is probably the largest in a population of similar size worldwide. The familial clustering observed can only be explained by cofactors in addition to HTLV-1. Some epidemiological definitions of the disease would have missed many true cases and they should be revised.

B.634

PREVALENCE OF HTLV I/II INFECTION IN BLOOD DONORS AND HIGH RISK GROUPS IN THE U.S.

Steaffens, J.*; Palker, T.**; Krochmal, E.*; Mann, T.*; Osame, M.*** and Lee, Helen* *Abbott Laboratories, North Chicago, IL, USA **Duke University Medical Center, Durham, NC, USA ***Kagoshima University Kagoshima, Japan

OBJECTIVE. To determine the prevalence of HTLV I exposure among plasmapheresis donors and high risk populations in the U.S.
METHODS. Specimens from IV drug abusers (IVDA), blood donors and high risk groups such as hemophiliacs and homosexuals were collected between 9/87 and 10/88 and tested for antibodies to HTLV I by EIA. Repeat EIA positive samples were confirmed by Western blot and SDS-RIPA.
RESULTS.

CATEGORY	NO. TESTED	EIA +	% CONFIRMED
IVDA	1092	226	0.04
Volunteer Blood Donors	66513	24	0.23
Plasmapheresis Donors	6200	14	0.23
Hemophiliacs	165	0	0.00
Homosexuals	152	2	1.30
ATL	41	39	97.5
Contacts of ATL	40	15	68.2
TSP/HAM	62	59	96.3
Contacts of TSP/HAM	12	5	41.7

CONCLUSION. IVDA constitute the main reservoir for HTLV I/II infection in the U.S. (12.5% by HTLV I alone and a further 6.2% HTLV I coinfected with HIV). Unlike HIV, hemophiliacs and homosexuals are not risk groups. Plasmapheresis donors show a five times higher seroprevalence rate when compared with volunteer donors.

B.636

DETECTION OF EARLY HTLV-I SEROCONVERSION (SC)

Manns, Angela*; Murphy, E.^{x}; Wilks, R.^; Hanchard, B.^; Drummond, J.+; Waters, D.+; Swanson, P.#; Lee, H.#; Blattner, W.*; *NCI, Bethesda,MD, ^{x}UCSF, San Francisco, CA, ^Min. of Health and UWI, Jamaica; +PRI,Frederick, MD, #Abbott,Chicago,IL.

Objective. Evaluate sensitivity of HTLV-I screening and confirmatory assays during SC among transfusion recipients (REC).
Methods. Pre-transfusion negative exposed REC from Jamaica, followed at monthly intervals, were tested by whole virus (wv) (DuPont and Abbott) and recombinant envelope (env) (Cambridge Biosci.) EIA, Western blot (WB), and radioimmunoprecipitation (RIPA) using HUT 102-B2/DA202 cell lines. McNemar's test was used to detect differences in sensitivity.
Results. 12 of 66 exposed REC, 9 with >10mos. of follow-up, and 8 with persistently positive SC patterns were analyzed. 58/93 samples were WB p19+p24 positive. WB was used as reference for comparing test performance:

EIA1	EIA2	ENV	FDA+
40/58	44/57*	58/58	48/58
(69%)	(77%)	(100%)	(83%)

*one sample not tested by EIA2; +FDA criteria 2 gene groups(MMWR,Dec88)

WB was more sensitive than EIA1 and EIA2; *env* EIA was as sensitive as WB, but specificity was not evaluated. WB detected antibody earlier than other methods. Early gag protein patterns preceding "FDA" SC were either p19 only, p24 only, or p19+p24 +/- other bands. Sensitivities between the two wv EIAs were not significantly different (p=.35).
Conclusion. Two wv EIAs had comparable sensitivities in this population of exposed transfusion recipients. Patterns showing either p19 or p24 only preceded FDA seroconversion criteria via WB determination. *Env* EIA may be an alternative to RIPA as a confirmatory test.

B.638

HIV P24 ANTIGEN IN ASYMPTOMATIC, PGL AND AIDS PATIENTS AT GAFFRÉE & GUINLE UNIVERSITY HOSPITAL, RIO DE JANEIRO, BRAZIL.

Sion, Fernando Samuel*; Salermo-Gonçalves, R.*; Quintães, E.P.*; Graça, M.H.P.*; Morais de Sá, C.A.*; Castilho, E.A.** et al.
* Gaffrée & Guinle University Hospital, Rio de Janeiro University (UNI-RIO) - Brazil.
** FIOCRUZ

Objective: To determine the presence of p24 antigen in patients with different clinical status of HIV infection.
Methods: Serum HIV p24 antigen measured by antigen capture ELISA (Abbott$^{(R)}$ Laboratories, North Chicago, Il. USA) was perfomed in 125 patients who met the Surveillance case definition of HIV infection by Centers for Disease Control (MMWR, 35(20):334, 1986) distributed as GROUP IV = 41, GROUP III = 30 and GROUP II = 54.
For statistical analysis we used the statistics χ^2 (Chi-square), watching for the linear tendency (Armitage, P - Statistical Methods in Medical Research - John Wiley and Sons - N.Y., 1971).
Results: Overall, 52 of 125 patients tested for antigenaemia were positive (41,6%). The distribution of these patients according to CDC's criteria is shown in following table:

CDC'S GROUPS	TOTAL NUMBER	ANTIGENAEMIA	
		NUMBER	%
IV	41	32	78,5
III	30	10	33,3
II	54	10	18,5

$\chi^2 = 35,106$ P < 0,001 χ^2_T for departures from linear trend = 2,08 P < 0,05
Conclusions: There is a clear evidence of association between antigenaemia and clinical status. There is also a definite trend which results in approximately equal increases in the proportion of presence of P24 antigen as it changes successively to more severe categories of HIV infection.

B.639

INTRACUTANEOUS TESTS WITH UBIQUITOUS ANTIGENS AND CD4-CD8 DETERMINATIONS IN AIDS

Zeballos, Roberto; Cavalcante, N.; Freire, C.; Lewi, D.; Accetturi, C.; Mendes, N. et al..
Escola Paulista de Medicina, São Paulo, Brazil.

Objective. To correlate simple immunological parameters with the clinical classification of AIDS.
Methods. A total of 127 AIDS patients classified according to CDC criteria were tested in vivo with PPD, candidin, trichophytin and streptokinase--streptodornase; the absolute numbers of CD4 and CD8 lymphocytes were also determined.
Results.

	2 or more positive cutaneous tests	mean of CD4 cells/mm^3	mean of CD8 cells/mm^3
Groups II and III (n=61)	69%	760	1067
Group IVa (n=33)	30%	279	796
Groups IVc and IVd (n=33)	17%	179	481

Conclusion. A progressive decrease in the reactivity to intracutaneous tests with ubiquitous antigens and in the absolute numbers of CD4 and CD8 cells was observed across the clinical spectrum of AIDS, emphasizing the value of these procedures.

B.640

PREDICTIVE VALUE OF THE DETERMINATION OF HIV-1 Ag IN SERUM

Leal, M; Pineda, Juan A; Calderón, E; Navarro, MD; Rey, C; Lissen, E.
University of Seville. Seville. SPAIN.

OBJECTIVE: To assess the predictive value of the determination of HIV-1 Ag in serum.
METHODS: We have tested for HIV-1 Ag by EIA 212 serum samples sequentially collected from 51 Anti-HIV-1 positive patients. On an average, they had been followed during 42.10 11.9 months (range 24-73) and 4.15 1.11 (range 3-9) serum samples had been taken from each patient. All of the subjects were at the stage II or III of the current CDC classification for AIDS related diseases at the beginning of the study.
RESULTS: The overall follow-up time and the number of samples taken from each patient were similar for those developed AIDS and those that did not. Six patients were found to be antigenemic at entry. Eight of the remaining 44 seroconverted during the follow-up. Seven of the 14 (50%) individuals (6/10 hemophiliacs, 1/2 drug-addicts and 0/2 homosexual men) who were found to be antigenemic in some time developed AIDS (stage IVc). The passage of time from the first evidence of HIV-1 Ag to the diagnosis of AIDS ranged from 0 to 73 months. All of the remaining 37 patients are still at the same clinical stage.
CONCLUSION: These results show a close association between the presence of HIV-1 Ag in serum and poor prognosis of HIV-1 infection. On the other hand, the rate of AIDS developing among antigenemic patients observed by us is one of the highest reported so far.

B.641

ASPECTS CLINIQUES HIV1 ET HIV2 ET CLASSIFICATION DE BANGUI

Sow Ab.*; Coll Awa Marie*; Faye/Ndao M.A.*; Diouf G.*; Feller-Dansokho E.*; Diop B.M.* et al*.
* Service des Maladies Infectieuses, C.H.U. de Dakar.

Objectifs. Evaluer la sensibilité et la spécificité des critères de diagnostic clinique du SIDA HIV1 définis à Bangui et proposer leur élargissement éventuel au SIDA HIV2.
Méthodes. Etude rétrospective de 73 cas de SIDA HIV1-HIV2 hospitalisés de janvier 1986 à décembre 1988 au Service des Maladies Infectieuses du C.H.U. de Dakar. Une cohorte de témoins (patients suspects mais séronégatifs) a été étudiée. Les critères de la classifications de Bangui ont été recherchés pour chaque cas et une étude comparative statistique a été effectuée.
Résultats. Sur 73 cas de SIDA :

49 HIV1
21 HIV2
3 double profil

Le sex-ratio est de 2.4. La grande majorité des malades HIV1 comme HIV2 présentent les signes majeurs de la classification de Bangui : amaigrissement > 10%, diarrhée > 1 mois et fièvre > 1 mois. Les manifestations cliniques HIV1 et HIV2 sont comparables dans notre série. Un pourcentage non négligeable de suspects ont eu une sérologie négative (sensibilité ?).
Conclusion. L'élargissement à HIV2 de la classification de Bangui est proposé mais une amélioration est possible.

B.642

ETUDE DE LA VALEUR DIAGNOSTIQUE DU WESTERN BLOT CHEZ 113 CONGOLAIS

M. Rosenheim*, D. Kerouedan*, P. M'Pelé**, N. Copin**, F. Yala**, A. Itoua-Ngaporo**, M. Gentilini*
*Dpt de Médecine Tropicale, Hôpital Salpêtrière et Unité INSERM 313, 47 Bd de l'Hôpital, Paris, France. **Hôpital Général de Brazzaville, Congo.

Méthode
Il s'agit d'une enquête de type rétrospective. Les cas sont les patients répondant à la définition clinique du SIDA (effectif=64). Les témoins sont les donneurs de sang considérés (effectif=49). Les sérums ont été répartis en pas de bande ou trace, et bande nette.
Résultats
Les malades ont plus souvent des Ac gp41 : chi2 = 6,25, p = 0,012, odds ratio (or) = 2,17. La même constatation a été faite pour les Ac gp160 : chi2 = 8,44, p = 0,0037, or = 3,36.
Il n'a pas été trouvé de valeur aux Ac p25. Les sérums ont été répartis en présence d'au moins un des deux Ac anti-gp d'une part, et absence des deux Ac d'autre part ; une liaison a été également trouvée : chi2 = 13,2, p = 0,028, or = 5,56. La liaison persiste pour la gp160 lorsque l'on neutralise l'effet de la gp41, elle disparaît pour la gp41 lorsque la gp160 est neutralisée. Cependant, la liaison persiste pour la gp41 dans le groupe absence de gp160.
Discussion
Nous n'avons pas trouvé au Congo de liaison statistique entre le stade clinique et la présence d'Ac p25. Nous avons montré qu'est associée à un mauvais pronostic la présence d'Ac gp160, la présence d'Ac gp41 chez les patients n'ayant pas la gp160.

B.643

DETECTION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV)DNA SEQUENCES IN SEROPOSITIVE PATIENTS AND SERONEGATIVE AT RISK SUBJECTS BY POLYMERASE CHAIN REACTION (PCR).

Fabrizio Ensoli, V.Fiorelli, I.Mezzaroma, F.Aiuti
Dept. of Allergy and Clinical Immunology, University of Rome, Rome, Italy

Objective: To investigate the earlier stage of the infection we detected HIV-1 DNA sequences in seronegative people at high risk as drug addicts and partners of seropositive subjects and seropositive patients classified according to CDC criteria. Normal blood donors were employed as controls.
Methods: Genomic DNA's collected from PBMC of seropositive and seronegative people were subjected to forty cycles of amplification. Two primer pairs for different conserved regions of the env gene were used. Specificity of amplification products was confirmed by Southern Blot. Serology was assessed by Western Blot; antigenemia by an Elisa system.
Results: Almost all seronegative poeple at high risk were confirmed negative by DNA amplification; individuals that resulted positive for HIV sequences also seroconverted after a few weeks. On the other hand no HIV sequences were detected with these primer pairs in a small percentage of seropositive but antigenemia negative patients.
Conclusion: PCR coupled with serological techniques is very useful to investigate the HIV infection especially in those cases in which serology remains silent or unclear. Studies are in progress with primer pairs for different regions of HIV genome to better characterize the integrated sequences during the disease.

B.644

CONTROLE DE QUALITE DES TESTS DE DEPISTAGE ET DE CONFIRMATION DES ANTICORPS ANTI HIV EN 1988

MOUILLOT L.[1,2], FRANCOIS E.[1], CHEINEY I.[1], COUROUCE A.R.[2]
et le groupe retrovirus.
1 Laboratoire National de la Santé - Département de Biologie Médicale Paris France.
2 Société Nationale de Transfusion Sanguine.

Objectif : Contrôle de qualité national des laboratoires déclarant pratiquer le test de confirmation (Western Blot) des anticorps anti HIV - 160 laboratoires.
Méthode : Les laboratoires ont reçu 3 envois de 4 échantillons de plasma, sur lesquels ils effectuent conformément à la circulaire du 24-02-87, deux tests de dépistage et un test de confirmation. Les 12 plasmas correspondent à : 6 HIV1 dont 3 débuts de Séroconversion et un cas de sida, 3 non spécifiques 2 p25, 1 p18, 2 négatifs, 1 HIV2.
Résultats : 8 réactifs de dépistage et 3 réactifs de confirmation ont été utilisés. Au total : 94 erreurs sur 1472 diagnostics ont été faites par les laboratoires tous réactifs confondus (soit 6,3 %).

	HIV1	HIV2	non spécifique	négatif
% d'erreurs de diagnostic	8,2 %	4,1 %	7 %	0,8 %

Les résultats des laboratoires en fonction des réactifs utilisés seront détaillés.
Conclusion : Ce contrôle a permis une amélioration des performances des utilisateurs et des réactifs.

B.645

THE USE OF GRAPHIC ART TO MEASURE NEUROPSYCHOLOGICAL FUNCTION IN HIV-INFECTED PERSONS

Spechko, Phyllis* and Peabody, B.**.
*UCSD Medical Center, **AIDS ART Project, San Diego, CA, USA.

Objective. To measure neuropsychological function in people with HIV infection through their artwork.
Methods. Twice-weekly, 3 hour sessions for HIV-infected persons for art therapy/instruction generated written and photographic observations of artwork and behavior of 75 patients over 4½ years. In an unstructured, group setting, an AIDS-sensitive therapist familiar with multiple art media (water-based paints on paper, oil and chalk pastels, inks, oil paint on canvas, markers, collages using art tissue and "found" objects) developed close relationships with patients leading to verbalization of problems and evidence of patient's physical and neurological deficits.
Results. Illustrative case studies of 5 AIDS patients demonstrate that changes in composition, subject matter, and color selection correlated with 1) progressive cognitive and affective deterioration (2 pts), 2) improved physical and cognitive status during AZT therapy (1 pt), and 3) incipient seizures (2 pts). For example, within hours to days of first painting characteristic, red, vertical stripes, 2 patients had generalized seizures.
Conclusion. In addition to its therapeutic value, artwork may provide a useful diagnostic approach to neuropsychological dysfunction in AIDS by illustrating changes in cognitive function and affect and by predicting seizures.

B.647

ADVERSE REACTIONS TO TRIMETHOPRIM-SULFAMETHOXAZOLE (TMP-SMX) TREATMENT OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP) IN ADIS .

González-Lahoz,J.,Moreno,V.,Polo,R.,Martínez,R.,Adrados,M.,Agudo,C.G.
Instituto de Salud Carlos III. Hospital del Rey . Servicio de Medicina Interna-I .

Toxic effects of TMP-SMX treatment of PCP are frequent in American-white patients with AIDS . Better tolerance to this treatment has been reported in Non-american AIDS patients. Our experience is reported here .
Methods: 43 patients with HIV infection and a first episode of PCP diagnosed by bronchoscopy with bronchoalveolar lavage were retrospectively evaluated. Patients received TMP 20 mg./Kg.day and -SMX 100 mg./Kg. day for at least 7 days. Mean age was 30.2 years (20-56). 35 patients werw male. 31 patients intravenous drug abusers (IVDA), 9 homosexual men, 1 heterosexual parther of IVDA - and 2 had no recognizable risk factor.
Results: Adverse effects were identified in 23 patients (53.4%):

- Hepatic: aminotransferases: 2-5 times normal (or value at entry): 7 (16.2%)
- Neutropenia: 11 (25.5%): <500: 3.
  500-1000:8.
- Rash: moderate: 3 (6.9%)
  severe: 1 (2.3%)
- Renal: creatinine: 1.5-3 mg./dl.:3 (7.6%)
  > 3 mg./dl.:0
- Vomiting: 8 (18.6%)

Discontinuation of treatment because of severe toxicity: 6 (13.9%):

- Creatinine: 1.5-3 mg./dl.: 1.
- Neutropenia: ≤ 500 : 3.
- Neutropenia (500-1000)+vomiting severe: 1
- Rash severe: 1 .

Comments: Although toxicity is frequent, discontinuation of TMP-SMX treatment is needed in a minority (13.9%) of patients. Manifest differences in rash frequency between our patients and American-white AIDS patients are observed .

B.646

OUTCOME OF ADVANCED MATERNAL AIDS IN OFFSPRINGS

*Devachi, Farzin, and *Kabena, M.
Department of Pediatrics, Mama Yemo Hospital, Kinshasa, Zaire.

Objective: To define the outcome of advanced maternal AIDS in offsprings.
Methods: We followed 20 infants born to mothers with advanced clinical AIDS.
Results: Eighteen mothers had produced 2 twins and 16 singles. Mothers were all ill at the time of delivery. Four died within 4 weeks of giving birth. Two had tuberculosis and one had Kaposi's Sarcoma. The others were hospitalized for AIDS. All 20 babies were born small for age. Six babies were born at term weighing from 1830-2500 grams. Fourteen were born at 32-38 weeks of gestation, weighing from 1000-2000 grams. All newborns were doing poorly at birth and manifesting the following clinical signs after birth: 20 (100%) with asthenia, 13 (65%) with diarrhea, 13 (65%) with respiratory infections, 9 (45%) with fever, 9 (45%) with anemia, 8 (40%) with oral candidiasis, 6 (30%) with vomiting, 3 (15%) with neurological complications, 3 (15%) with physiological jaundice, 2 (10%) with pyoderma and 1 (5%) with splenomegaly. In the course of hospitalization, one term infant was sent home in a stable condition. A second infant, who weighed 1540 grams at birth, gained 280 grams and was discharged in satisfacotry condition. Of the remaining 18 newborns, 6 died within the first week of life and 12 died within 2 months of birth.
Conclusion: HIV seropositive mothers infect 30-40% of their offsprings, however, in our series, advanced maternal AIDS was associated with a significantly higher maternal and neonatal morbidity and mortality. There was 22% maternal and 90% neonatal demise shortly after delivery.

B.648

ADVERSE EFFECTS OF ZIDOVUDINE (AZT) IN PATIENTS WITH HIV INFECTION.

ME VALENCIA,V PINTADO,M FRANCES,P LAVILLA,JML DUPLA,A GIL
Hospital La Paz. Madrid. Spain.

OBJECTIVE. Assesment of adverse effects (AE) to Zidovudine in patients with HIV infection in an intensive pharmacologyc surveillance program.

MATERIAL AND METHODS. 33 patients were entered. 22 patients fulfilled AIDS criteria, 3 patients had a group III (CDC) infection, 3 group IV-B infection and 3 group IV-C2 infection. 24 patients were drug abusers, 6 were homosexuals, 2 bisexuals, and one was a heterosexual partenaire of an HIV carrier. Mean age was 30 years (Range: 24-50). 25 were males. AZT dose was 1200 mg/day. This dose was modified upon haematologic parameters. An intensive pharmacologyc surveillance program for detection of AE, with twice a month evaluation during first three months, and thereafter monthly was begun.

RESULTS. 1) Haematologycal toxicity. 14 patients showed anemia (42%). In 9 it was severe (32%) (Hemoglobin < 7.5 gr%). Anemia usually begun between 8th and 10th week of treatment. It was recurrent anemia, and required transfusion of 9 units of eritrocyte concentrates per patient, as a mean. Macrocytosis was observed in 61% of cases, neutropenia in 43%. 3 patients showed agranulocytosis. 2) Gastrointestinal toxicity. In 2 patients (7%) severe nausea and vomiting required withdrawal of therapy. 3) Dermatologyc toxicity. 4 patients showed blue-colored nails (14%), and one patient showed difuse cutaneous hyperpigmentation. 4) Hepatic toxicity. In one case there was a transaminase elevation during the 2nd week, that normalised after withdrawal of therapy. 5) No renal nor neurologic toxicity was observed.

CONCLUSIONS. 1) Haematologic toxicity was the most severe AE observed, requiring modification of therapy, but not supression. 2) Gastrointestinal toxicity, although uncommon, was the poorer tolerated AE. 3) Changes in cutaneous and ungueal pigmentation are a new contribution to the AE constellation of AZT.

Recherche fondamentale (biomédicale)

Basic Research (Biomedical)

Mécanismes de pathogenèse du VIH
Mechanisms of Pathogenesis of HIV

M.C.0.1

VIRAL AND HOST FACTORS INFLUENCING THE PROGRESSION TO AIDS.

Jay A. Levy, Cheng-Mayer, C., Walker, C. and Homey, J.
~~Dept. of Medicine~~ and the Cancer Research Institute, University of California, School of Medicine, San Francisco, CA 94143.

A basic question in AIDS is why the time for development of clinical symptoms and progression to disease differs widely among HIV-infected individuals. The vast heterogeneity in the biologic, serologic, and molecular properties among HIV strains offers one explanation. In particular, their differential ability to infect different cell types (both CD4+ and CD4-), to replicate rapidly to high titer in these cells, to cause cytopathic changes, and to be neutralized by various sera has been demonstrated. Moreover, certain isolates appear more sensitive to serum enhancement. Furthermore, through the interaction of the HIV nef gene product with the viral LTR, a state of latency can be induced that may delay or prevent disease in the infected individual. Our studies have indicated, for example, that individuals with a rapid progression to disease have viruses that replicate rapidly and are more cytopathic with a wide cellular host range. Moreover, brain and blood isolates can be distinguished by their relative ability to grow in macrophages and lymphocytes, to modulate the CD4 antigen on T cells, and by their serologic properties. Molecular and protein studies have indicated a relationship of some of these biologic activities with changes in protein and genetic structures.

The host immune response also plays a substantial role in determining the HIV pathogenic process. Antibodies that enhance virus infection can permit HIV spread to several different cell types including lymphocytes, macrophages and fibroblasts. Cellular immune responses can destroy virus-infected cells or suppress virus release via the production of antiviral cytokines or mechanisms involving cell:cell interaction. Thus, the dynamics of a quickly changing replicating virus and an active immune system provides an important "key" to whether an individual has a long asymptomatic course or a rapid progression to AIDS.

M.C.0.3

ROLE OF N-LINKED GLYCOSYLATION IN HIV INFECTION.

Gluckman Jean-Claude*, Fenouillet, E.*, Gattegno, L.**, Clerget-Raslain, B.*, Montagnier, L.***, Bahraoui, E.***.
*CERVI, Hôpital de la Pitié, Paris ; ** Laboratoire de Biologie Cellulaire, Faculté de Médecine Paris-Nord ; *** Unité d'Oncologie Virale, Institut Pasteur, Paris, France.

N-linked glycans represent 50% of the MW of HIV *env* gene product, and glycosylation sites are well conserved among different isolates. Carbohydrate oligosaccharides (CHO) are likely to be prominent structures on the virus surface, although their precise role is still poorly understood. We have demonstrated that complete enzymatic removal of glycans from recombinant gp120 or gp160 (rgp120/160) in the absence of denaturating agents does not significantly modify *in vitro* interaction with its CD4 receptor : deglycosylated rgp120/160 attached to soluble or membrane-bound CD4 with comparable affinity and inhibited fusion of HIV-infected and non-infected cells to the same extent than glycosylated rgp120/160. This apparently contradicts a previous observation that deglycosylated native viral gp120 (ngp120) displayed markedly reduced binding capacity to CD4. Differences between these observations may stem from technical conditions, or they may be related with differences in the glycosylation patterns of rgp120 and ngp120 that could result in functional differences of the glycan moieties. In addition, experiments conducted with glucosidase inhibitors that interfere with early oligosaccharide processing indicate that CHO may play a role at a post-translational level and be involved in other functions of gp120/160 in relation with post-binding events. *Env* glycoproteins may also interact with extra-cellular or cell-membrane lectins, especially on mononuclear phagocytes. On the other hand, our recent data suggest that gp120 behaves as a lectin, binding β-D-N acetylglucosamine. These properties might be used by HIV to attach to cell membranes independently of CD4 and be one of the explanations that HIV can infect CD4- cells under some circumstances. Finally, CHO chains may intervene in the immune response to HIV either by directing responsiveness to certain sites or by masking part of gp120/160 epitopes.

M.C.0.4

NEW APPROACH TO THE STUDY OF OLIGOSACCHARIDES AS DETERMINANTS OF THE TISSUE TROPISMS OF HIV-1.

Ten Feizi
MRC Clinical Research Centre, Watford Road, Harrow, Middlesex, United Kingdom

The envelope glycoprotein, gp120, of the human immunodeficiency virus (HIV-1) is highly glycosylated with a diverse array of N-glycosidically linked oligosaccharides[1-3]. We have proposed[1] that these oligosaccharides which are likely to be prominent structures on the virus surface, are candidate attachment and addressing factors in the host at various stages of the virus cycle. This communication will be concerned with the molecular dissection of oligosaccharide-mediated interactions by a novel approach involving the generation of oligosaccharide probes from the envelope glycoprotein.

M.C.O.5

GENETIC ANALYSIS OF SIV DERIVED FROM MANDRILL (SIV_{MND})

Tsujimoto,H.*; Hasegawa,A.**; Cooper,R.W.***; Fukasawa,M.*; Miura,T.****; Hayami, Masanori**** *et al.*
*Institute of Medical Science, University of Tokyo, Japan, **Toa Nenryo Kogyo K.K., Japan, ***Centre International de Recherches Medicales de Franceville, Gabon, ****Institute for Virus Research, Kyoto University, Japan.

Objective. To understand genetical relationship and phylogenic epidemiology of HIV/SIV group.
Methods. Two isolates of SIV were obtained from apparently healthy mandrills in Gabon. One of them was molecularly cloned from the circular replicative intermediate DNA by linearization with one-cutting restriction enzyme, and totally sequenced by the methods of Sanger et al.
Results. Gene structure of SIV_{MND} is almost equal to other HIV/SIV, but the open reading frames such as *vpr* and *vpx* were uncertain. The amino acid sequence homologies of each open reading frame to other HIV/SIV (HIV-1, HIV-2, SIV_{MAC} and SIV_{AGM}) were almost equal, about 50% in *gag*, 50-60% in *pol*, and about 30% in *env* region.
Conclusion. The SIV_{MND} was totally sequenced and was considered to be a new member of HIV/SIV group, equally distant from other HIV/SIV including SIV_{AGM}. It suggest the species-specificity of SIV group and unlikeliness of recent interspecies transmission among primates.

M.C.O.6

GENOMIC DIVERSITY OF SIV_{AGM} GROUP OF VIRUS.

Fukasawa,M.*;Ohta,Yoshihiro*;Sakuragi,J.**;Miki,K.***;Isahakia,M.****;Hayami,M.**et al.
*Institute of Medical Science,Tokyo University,**Institute for Virus Research, Kyoto University,***Toa Nenryo Kogyo,Japan,****Institute of Primate Research, National Museums of Kenya,Kenya.

Objective.To estimate the genomic diversity among various isolates of simian immunodeficiency virus from African green monkey (SIV_{AGM}).
Methods.The full- or partial-length of viral DNA of 4 SIV_{AGM} isolates from African green monkey originated from different places, SIV_{AGM}[TYO-2], [TYO-5], [TYO-7] and [KE-1] were molecularly cloned from their viral infected cell lines and were compared with previous reported isolate, SIV_{AGM}[TYO-1] by restriction endonuclease mapping.
Results.All the isolates are strongly hybridized with SIV_{AGM}[TYO-1] probe, but not with probes of HIV-1, HIV-2, SIV_{MAC} and SIV_{MND}. SIV_{AGM}[TYO-2] and [TYO-5] are as long as [TYO-1] and once digested by Eco RI, however, their restriction sites (including Eco RI, Hind III, Kpn I, Sac I, Xba I etc.) shows great divergence not only in their env region but also in other regions. The genome sizes of SIV_{AGM}[TYO-7] and [KE-1] are shorter than those of others, and are digested by Eco RI twice or more.
Conclusion.The genomic diversity of SIV_{AGM} group might be as well as (or greater than) those of other HIV/SIV groups although all the isolates belong to the one group, SIV_{AGM}. The heterogeneity was also observed in the virus isolated from one animal as seen in HIV-1 infected person.

M.C.O.7

PROSPECTIVE CLINICAL, IMMUNOLOGICAL, AND VIROLOGIC FOLLOW-UP OF AN INFECTED LAB WORKER (LW)

Blattner, W.*; Nara, P.*; Shaw, G.+; Hahn, B.+; Kong, L.+; Matthews, T.x; Bolognesi, D.x; Waters, D.^; and Gallo, R*. *National Cancer Institute, Bethesda, MD; +U of Alabama, Birmingham, AL; xDuke Univ., Durham, NC; ^PRI, Frederick, MD. U.S.A.

Objective: Follow natural history of accidental laboratory acquired infection with H9/HTLV-III_B strain.
Methods: Sequential isolations (SI) obtained by cocultivation (Science 239:68, 1988). Neutralizing antibodies (NA) measured by virus infectivity syncytium inhibition assay (AIDS Res. and Hum. Retro. 3:238, 1987). Nucleotide and deduced amino acid sequences of the viral envelope gp120 immunodominant loop region (a 302-337) determined for cloned SI. CD4 counts by FACS.
Results: LW is clinically healthy. CD4 counts show an initial lymphopenia (CD4 (375) and CD8 (426) 11 months after initial sample), rising over the next six months to a currently stable value at 28 months of CD4 (860) and CD8 (470). NA responses show an initial low titer type specific immune response which broadened over time. Heterologous hyperimmune goat anti HTLV-III_B sera used to block infection by SI in a syncytia inhibition assay demonstrated a shift in neutralization profile away from parent virus. Sequential point mutations representing a total of 3 new amino acid substitutions over a 28 month period in the immunodominant loop were detected.
Conclusion: Cumulative changes in immunologically relevant domain of the HIV-1 envelope may reflect serial mutations of the virus or selection of coincidentally present substrains as part of a repertoire to avoid the host immune response.

M.C.O.8

EVOLUTION OF THE BIOLOGICAL PHENOTYPE OF SEQUENTIAL HUMAN IMMUNODEFICIENCY VIRUS (HIV) ISOLATES IN SEROCONVERTING HOMOSEXUAL MEN,

M. Tersmette, R.E.Y.de Goede, F. de Wolf*, J. Goudsmit*, J.G. Huisman, F. Miedema, Central Lab. Netherl. Red Cross Blood Transf. Service and Lab. of Exp. and Clin. Immunology of the Univ. of Amsterdam, *Academic Medical Centre, Amsterdam, The Netherlands.

Two types of HIV isolates can be distinguished: syncytium-inducing (SI), high-replicating isolates with a broad host range and non-syncytium-inducing (NSI) isolates only replicating in peripheral blood mononuclear cells (PBL) (Tersmette et al.,J.Virol.(1988) 62:2026-2032). From stable asymptomatic seropositive persons only NSI isolates were recovered. SI isolates were only recovered from persons progressing to ARC or AIDS. To investigate whether syncytium-inducing (SI) HIV isolates, associated with CD4+ cell depletion and disease, are present from seroconversion onwards or emerge in the course of HIV infection, and to account for the paradox that apparently transmission of HIV by an SI isolate carrier does not generally result in an infection with an SI isolate in the recipient, we analysed the biological phenotypes of sequential HIV isolates obtained from a cohort of seroconverting homosexual men. The results of this study allow for the following conclusions: 1) Early after seroconversion only non-syncytium-inducing (NSI) isolates are recovered; 2) SI isolates, if detectable, emerge in the course of HIV infection; 3) Upon transmission, SI isolates are presumably suppressed in the host. The results of this study support a model for AIDS pathogenesis in which the duration of the latency period between seroconversion and AIDS is determined by the capacity of the host immune system to suppress the emergence of virulent, CD4+ cell-depleting HIV variants.

M.C.O.9

REPLICATIVE CAPACITY OF SEQUENTIAL VIRUS ISOLATES FROM HIV-1-INFECTED SUBJECTS AND RELATIONSHIP TO CLINICAL PROGRESSION

Eva M. Fenyö*; Albert, J.**; Morfeldt-Månson, L.* and Åsjö, B.* Departments of Virology, Karolinska Institute* and National Bacteriological Laboratory**, Stockholm, Sweden.

Objective. To study changes in the replicative capacity of HIV-1 that occur in the same individual over time.
Methods. Eight patients were followed with sequential virus isolations during a 30-months observation period.
Results. Patients with stable lymphadenopathy syndrome (LAS) yielded slow/low viruses on repeated isolations. Viruses isolated from patients during the period of clinical progression from LAS to AIDS-related complex (ARC) showed increasing replication potential. In sequential virus isolates from patients with ARC, the replication potential of sequential virus isolates fluctuated during the observation period. Accordingly, changes from slow/low to rapid/high and back to slow/low replication pattern, could be observed. One patient showed a rapid development of severe immunodeficiency, progressing from LAS to AIDS within one year. Viruses isolated during this period replicated with increasing efficiency in vitro.
Conclusion. The results show that HIV-1 isolates with distinct replicative capacity may be obtained from the same individual over time. Rapid clinical progression is often accompanied by the emergence of variant viruses with increased replicative capacity.

M.C.O.10

CD4+ T LYMPHOCYTES FROM THE PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) OF HEALTHY SEROPOSITIVE INDIVIDUALS HARBOR THE HIV-1 PROVIRAL SEQUENCES

Psallidopoulos, Miltiades*; Schnittman, S.+; Baseler, M.#; Fauci, A.S.+; Lane, C.H.+ and Salzman, N.P.* *Georgetown University, Washington, DC USA; #PRI, Federick, MD USA; and +NIAID, National Institutes of Health, MD USA

Objective. To demonstrate the presence of integrated proviral HIV-1 in PBMC of healthy seropositive individuals and determine the viral load and the specific subset of PBMC that harbors the HIV-1 at early stages of the disease.
Methods. PCR amplification was performed on the subsets of PBMC obtained by fluorescence automated cell sorting from ten healthy, seropositive individuals using primers from LTR, gag and envelope conserved regions.
Results. HIV-1 proviral sequences were found in all subjects studies and the CD4+ T cell subpopulation which retains the CD4 surface molecule is the predominant cell that harbors HIV-1. In two cases (2/10) CD14+ (monocyte/macrophage) subsets also harbor HIV-1 but at a significantly lower level. Serial dilutions of sorted CD4+ T cells show that at least 1/1,000 - 1/10,000 cells are infected.
Conclusion. The cell populations that harbor HIV-1 are CD4+ T cells that continue to express the CD4 surface molecule. Healthy seropositive individuals have a 100 fold lower viral load than AIDS patients. Their immune system may be able to maintain a chronic or latent infection for extended periods of time when there are low levels of virus.

Les bases moléculaire et cellulaire des immunodéficiences provoquées par les rétrovirus
Molecular and Cellular Bases of Retrovirus Induced Immunodeficiencies

M.C.O.11 THE MURINE ACQUIRED IMMUNODEFICIENCY SYNDROME (MAIDS) IS CAUSED BY A DEFECTIVE RETROVIRUS

Huang, Ming*; Hanna, Z.*; Aziz, D.*; Simard, C.* and Jolicoeur, P.*,**.
*Clinical Research Institute of Montreal, Montreal, Quebec, Canada;
**Université de Montréal, Montreal, Quebec, Canada.

The Duplan strain of murine leukemia virus (MuLV) induces MAIDS, a disease showing striking similarities with human AIDS. We identified the etiologic agent of the disease as being a defective retrovirus having a 4.8 kbp genome. Sequencing of this DNA showed that the pol and env genes have been deleted and that the complete gag region has been conserved and harbors a novel p12 sequence. Using a cell-free translation system, the genome has been shown to encode a 60 kd gag fusion protein. The same protein was detected in non-producer cells harboring the defective genome and is not cleaved. N-tropic pseudotypes have been constructed with this virus and the role of helper virus in the disease is also being investigated using the Ψ2 encapsidation-negative system. This mouse model emphasizes the need to search for pathogenic defective retroviruses in AIDS.

M.C.O.12 INDUCTION OF IMMUNODEFICIENCY DISEASE BY FeLV AND RELEVANCE TO SIV- AND HIV-DISEASE

Mullins, James I.*, Hoover, E.A.**, Murphey-Corb, M.***, Donahue, P.R.*, Overbaugh, J.*, Poss, M.L.**, Edmonson, P.F.*, Hirsch, V.*, Martin, L.***.
*Harvard School of Public Health, Boston, MA, **Colorado State University, Ft. Collins, ***Delta Regional Primate Research Center, Covington, LA

Objective. We are developing animal models for AIDS using a feline leukemia oncovirus (FeLV-FAIDS) and a simian immunodeficiency lentivirus ($SIV_{mac-BK28}$). FeLV results have led to questions now being addressed in both the SIV-macaque model and in HIV-infected people.
Methods. Establish disease models and relevant in vitro correlates using molecularly cloned viruses, and identify viral genetic and biochemical factors which determine pathogenesis.
Results. Molecular clones of pathogenic FeLV-FAIDS genomes, isolated directly from tissue DNA were replication defective, whereas nonpathogenic clones replicated in vitro and in vivo (see Overbaugh et al). Defectiveness per se, however, is not required for pathogenicity since a replication competent pathogen could be created in vitro. Similarly, a molecular clone of $SIV_{mac-BK28}$ derived from extensively culture-passaged virus was highly replicative in vivo and in vitro and only weakly pathogenic in vivo. However, passage of $SIV_{mac-BK28}$ through a macaque that eventually died from SIV-disease resulted in evolution of a more acute pathogen. The length of the transmembrane gene did not influence virus pathogenicity significantly, although the TM was altered by the type of selection imposed - a shorter coding region was selected for in vitro, and a longer gene/protein was selected in vivo (see Edmonson et al). The T-cell killing determinants of an FeLV-FAIDS clone were mapped to the envelope glycoprotein gene and were correlated with several biochemical features of the cytopathic gp70. Killing is also prevented by exposure of infected cells to neutralizing antisera (see Donahue et al).
Conclusions. Strong viral genome selection occurs in vitro as well as in vivo, and in vitro propagation may obscure viral gene coding capacity as well as select against acute pathogens. T-cell killing, at least in the FeLV-FAIDS system, likely occurs from a failure or delay in the establishment of superinfection interference.

M.C.O.13 ROLE OF ANTIBODIES, CYTOKINES, AND VIRUS VARIATION IN SIV/SMM INDUCED DISEASE.

Fultz, Patricia*; Stricker, R.**; Montagnier, L.***; Sonigo, P.***; McClure, H.*; and Anderson, D.*.
*Yerkes Primate Research Center and Department of Pathology, Emory University, Atlanta, GA, **Cancer Research Institute, University of California, San Francisco, CA, USA, ***Institut Pasteur, INSERM, Paris, France.

Objective. To identify the role of antibodies, cytokines, and biologic and genetic variation in disease associated with different isolates of SIV/SMM.
Methods. Antibody responses, including neutralization and autoantibodies, and cytokine levels in serum from mangabeys and macaques were compared. SMM-9 and SMM-PBj14, a variant that causes rapid death, were analyzed for phenotypic and genotypic properties which included the ability to replicate in and their effects on PBMC from various species as well as cloning and sequencing.
Results. Comparison of humoral immune responses to SIV/SMM in mangabeys and macaques showed that disease in macaques was associated with the presence of autoantibodies but not with total or neutralizing antibody titers. In contrast to SMM-9, the lethal SMM-PBj14 strain, which was associated with the presence of high levels of TNF-alpha in serum, induced PBMC from macaques and mangabeys to proliferate, replicated in resting PBMC in the absence of exogenous IL-2, formed syncytia with Sup-T1 cells and had a transmembrane protein of 45-46,000 daltons that lacked a premature stop codon.
Conclusions. Humoral immunity does not appear to be a major factor in the pathogenesis of SIV/SMM for macaques and mangabeys. Autoantibodies and TNF-alpha, however, may play a role in disease induction by SMM-9 and SMM-PBj14, respectively. SMM-PBj14 appears to have multiple mutations, some of which affect env-encoded proteins and perhaps regulatory proteins. (NIH RR-00165)

M.C.O.15 EFFECT OF SOLUBLE RECOMBINANT HUMAN CD4 (sCD4) ON INFECTIVITY OF SIX MONOCYTOTROPIC STRAINS OF HIV (MO-HIV)

Gomatos, Peter John, Gendelman, H.*; Stamatos, N.; Fowler, A.**; Hoover, D.; Burke, D.; Tramont, E. and Meltzer, M. S. Walter Reed Army Inst. Res., *Henry M. Jackson Fndn., **SRA Tech., Inc. , Washington DC ,USA.

Objective. Determine effect of sCD4 on the infectivity of MO-HIV in monocytes.
Methods. MO-HIV were isolated from 6 HIV seropositive patients by cocultivation of blood mononuclear leukocytes with recombinant human colony stimulating factor-M (Cetus Corp., Emeryville CA)-treated adherent monocytes from normal donors. Infectivity of MO-HIV for monocytes was monitored by measurement of p24 and reverse transcriptase activity in culture fluids.
Results. Infectivity of 1x10^5 TCID$_{50}$ HTLVIII$_B$ for the H9 T-cell line was completely inhibited (quantitated by inhibition of H9 syncytia formation and p24 antigen) by prior exposure of virus to 10 ug/ml sCD4 (Biogen, Boston MA) 37°C 30 min and continuous sCD4 exposure throughout the culture interval. In contrast, infectivity of 6 different MO-HIV was only partially inhibited by 10 ug/ml sCD4. Whereas the infectivity of strains 16 and 24 (1x10^3 TCID$_{50}$) was inhibited 100-fold by sCD4, that of strains 36, 37, and 38 was minimally (≤10-fold) inhibited. The effect of sCD4 on the prototypic MO-HIV, ADA, was intermediate: release of p24 into culture fluid was delayed, yet the ultimate level of p24 at 20 days was not different than control cultures. HIV-induced cytopathic effect on monocytes (formation of multinucleated giant cells) was evident with all MO-HIV with or without sCD4.
Conclusion. Exposure of MO-HIV to sCD4 partially inhibited infectivity in monocytes: the extent of inhibition varied with virus strain. Prior exposure of some MO-HIV to sCD4 may inhibit a required step in their growth cycle. It may be possible to select those patients who will respond favorably to treatment with sCD4.

M.C.O.16 HIV PERSISTENCE IN MONOCYTES INVOLVES NEGATIVE REGULATION OF VIRAL REPLICATION AND ESCAPE FROM IMMUNE SURVEILLANCE

Mikovits, Judy*; Razihuddin*; Gonda, M.** and Ruscetti, F.***
*BCDP, Program Resources Inc. Frederick, MD, **Lab. Cell Molec. Struct., PRI, Frederick, MD, ***Lab. Molec. Immunoreg., BRMP, NCI-FCRF, Frederick, MD,U.S.A.

Objective. To study HIV life cycle and persistence in cultured monocytes.
Methods. Standard viral, cellular and molecular techniques were used.
Results. A human monocytoid leukemic cell line, THP-1, and fresh elutriated monocytes were infected with isolates of HIV-1 and HIV-2. In the infected cells, the virus life cycle had distinct pathways. At first, all infections were productive with HIV-1 titers much higher than HIV-2 titers. On continuous passage, most cultures no longer produced detectable extracellular virus. These cultures either had provirus but no transcription of viral gene products (latency) or chronic low level expression with viral intracellular budding into vacuoles (VIB). Thus, failure to detect extracellular virus was related to either latency or intracytoplasmic sequestration of virions. In the case of VIB expression, LTR directed in vitro nuclear run-off transcription assays showed that cell nuclei contain materials that negatively regulate HIV transcription. Intracytoplasmic virions were infectious and caused viral-mediated T-cell cytolysis. Latent and VIB cultures had no detectable virus or gp-120 on the cell surface. Such cells were not lysed by IL-2 activated large granular lymphocytes while productively infected cells were efficiently lysed.
Conclusions. In HIV-infected monocytes, viral transcription can be negatively regulated such that viral expression can be either latent or restricted to intracytoplasmic viral retention. Infected monocytes not producing extracellular virus can escape immune surveillance and still be able to evoke viral induced T-cell pathology suggesting a mechanism for persistent HIV infection.

M.C.O.17 HIV-1 INFECTED MONOCYTES AS A TARGET FOR ADCC

Stanley, S. David*; Miller, N.**; Stine, K.*; Tyler, D.*; Bolognesi, D.*; and Weinhold, K.* *Duke University Medical Center, Durham, NC, USA. **National Cancer Institute, NIH, Bethesda, MD, USA.

Objective: To determine whether persistent viral reservoirs in HIV-1 infected monocytes can be eliminated by antibody dependent cellular cytotoxicity (ADCC).
Methods: Peripheral blood monocytes were isolated from leukapheresis products by Ficoll-Hypaque sedimentation, followed by differential density seperation on a discontinuous Percoll gradient. Cells were infected with the BAL isolate of HIV-1, and cultured in Teflon flasks in both the presence and absence of 100 units/ml of recombinant M-CSF . Culture supernatants and cell lysates were periodically monitored for p24 and reverse transcriptase activity, while infection was directly documented by in situ hybridization of HIV-1 RNA and DNA probes. At weekly intervals, infected monocytes were tested as targets in ADCC assays, with virally infected CEM.NKR cells serving as a positive control.
Results: At 21 days post infection, p24 concentrations in M-CSF treated and untreated culture supernatants were 99 ng/ml and 131 ng/ml, respectively. Culture supernatants for both conditions were shown to contain approximately 10^4 infectious units of HIV-1 per ml of solution. Virus infection was directly detected by in situ hybridization in 30% of M-CSF treated and 20% of untreated monocytes. Cell lysates confirmed the presence of virus, with 10^6 cells containing approximately 10 ng of p24. Despite the high degree of infection, neither M-CSF treated nor untreated monocytes were lysed in ADCC assays, while virally infected CEM.NKR cells were actively destroyed (45% lysis of these cells at a 50:1 E.T and a 10^5 dilution of anti-HIV-1 serum).
Conclusion: HIV-1 infected monocytes appear notably resistant to ADCC. This resistence not only provides an excellent sanctuary for virus within the host, but may also explain, in part, why recognized anti-viral immune mechanisms may be unable to eradicate infection.

M.C.O.18 ANTIVIRAL EFFECTS OF AMINO SUGARS: POTENCY OF N-BUTYLDEOXYNOJIRIMYCIN (Bu-DNJ)

Karpas, Abraham*; Dwek, R.A.**; Fleet, G.W.J.***; Jacob, G.S.** and Rademacher, T.W.**
* Dept. of Haematology, University of Cambridge Clinical School, Cambridge,UK.
**Glycobiology Unit, Dept. of Biochemistry, University of Oxford, Oxford, UK.
*** Dyson Perrins Lab, Dept. of Organic Chemistry, University of Oxford, U.K.

Objective. To assay amino sugars for anti-HIV activity relative to cytotoxicity for selection of a potential chemotherapeutic agent.
Methods. A series of compounds, including 5 aminosugars, was added to cultures of Karpas T-cells and Molt4 cells at different concentrations, in 96-well plates. Half of the wells were infected with HIV. The effect on T-cell replication was monitored by cell counts. The effect on HIV replication was assessed both by the inhibition of its characteristic cytopathic effect (giant and dying cells) and by determining the yield of infective particles (tissue culture infectious dose - TCID).
Results. A series of sugar analogues was found to inhibit both HIV-1 and HIV-2 replication in our T-cells. The inhibition in infectious HIV synthesis ranged between 10-10^5 fold, even at concentrations which did not interfere with cell division. Bu-DNJ was the most effective compound and long-term growth of infected cells in the presence of Bu-DNJ gradually decreased the proportion of infected cells, assayed by the IP method. Our results suggest that replication is associated with cytolysis (PNAS 85:9229, 1988).
Conclusion. Bu-DNJ was the most effective aminosugar to inhibit HIV replication and therefore could be used as a drug in a trial of patients with AIDS.

M.C.O.19 NOVEL MODE OF HIV REPLICATION IN PERSISTENTLY INFECTED MONOCYTOID CELLS: ACCUMULATION OF SELF-INTEGRATED, EXTRACHROMOSOMAL PROVIRUSES LEADS TO THE PRODUCTION OF DEFECTIVE VIRIONS.

C. David Pauza. The Salk Institute for Biological Studies, P.O. Box 85800, San Diego, California, U.S.A.

Objective. Examine alternative modes of replication that might explain the ability of HIV to establish and maintain a persistent infection in terminally differentiated and non-dividing cells of the monocyte/macrophage lineage.
Methods. Persistently infected monocytoid lines were established by HIV-1 infection of the U937 cells. The structure of HIV provirus in these cells and in subcloned cell lines, was examined by Hirt extraction of extrachromosomal DNA, restriction analysis, and blot hybridization. In addition, molecular clones of these unusual proviruses were obtained and characterized structurally.
Results. The extrachromosomal provirus in persistently infected monocytoid cells is a self-integrated, multimer; these unusual proviruses are denoted "nested self-integrates". Structural characterization indicated that these molecules arose via sequential integration of monomeric proviral circles into larger, pre-existing multimers. Conservation of restriction endonuclease sites is consistent with direct DNA to DNA replication of these proviruses and is inconsistent with a replication strategy that proceeds via the error-prone reverse transcriptase pathway.
Conclusion. This novel mode of HIV proviral DNA replication in monocytoid cells might explain paradoxical features of virus replication in normal monocytes and macrophages. It is generally accepted that provirus is integrated into the chromosome of dividing cells and that this is an obligatory stage in the infectious cycle. Monocytes and macrophages are non-dividing cells; a DNA-dependent mode of HIV replication could resolve this paradox and explain the ability of HIV to establish and maintain a persistent infection of monocytes and macrophages.

M.C.O.20 BIOLOGIC, BIOCHEMICAL AND MOLECULAR ANALYSES OF MONOCYTOTROPIC HUMAN IMMUNODEFICIENCY VIRUSES

Gendelman, Howard *[1]; Baca, L.*; Leader, M.*; Kriebel, P.**; Fowler, A.**; Hoxie, J.***; Roberts, C.*; Orenstein, J.****; Hussayni, H.**; Hoover, D.*;and Meltzer, M.*. *Walter Reed Army Instit. of Res./[1] H. M. Jackson Found., **SRA Tech., ****George Washington Univ. Med. Ctr., Washington, D.C., ***Univ Pa Med Ctr., Phila., Pa. USA

Objectives. To investigate the biology of monocytotropic HIVs.
Methods. Isolation of HIV by cocultivation of patient peripheral blood leukocytes onto lymphoblasts (T-cell HIV) or macrophages (MO HIV) are effective means of virus recovery. MO and T-cell HIVs were evaluated by propagation onto new monocytes and T-cells. Isolates were examined by restriction enzyme mapping of proviral DNAs, radioimmunoprecipitation (RIP) and CD4 binding assays.
Results. 20/23 MO isolates serially propagated on MOs produced HIV Ags and cytopathic effects. Eight simultaneously isolated (MO and T-cell HIVs) were studied for target cell tropism. During the first MO passage (P1), 5/8 T cell HIVs propagated on MO; 1/8 released p24 >1 ng/ml and 0/8 titered > 1:10. In contrast, 8/8 P1 MO HIVs propagated on MOs; 4/8 released p24 > 1 ng/ml and 4/8 titered > 1:10. The viral titer and p24 of MO and T-cell HIVs in P1 T-cell infection assays were identical; HIV Ags were > 7 ng/ml and titers > 1:100. Those T-cell and MO HIVs tested modulated CD4 and showed plasma membrane virus budding. Serial passage of MO and T-cell HIVs abrogated their abilities to efficiently infect heterologous cells. MO HIV show increases in gag/envelope proteins compared to T-cell HIV but bind CD4 by RIP of MO cell lysates. Restriction mapping of MO isolates reveal proviral heterogeneity.
Conclusion. Unique aspects in MO HIV-MO life cycle are demonstrated which may ultimately affect the persistence of HIV in the human host.

M.C.0.21 THE IMMUNODOMINANT NEUTRALIZATION LOOP OF HIV-1: BIOLOGICAL AND IMMUNOLOGICAL SIGNIFICANCE

Looney,D.[1]; Ivanoff,L.[2]; Rusche, J.R.[3]; Hoxie,J.[4]; Redfield,R.[1]; and Wong-Staal,F.[5]. [1]Walter Reed Retrovirus Research Group, WRAIR, Washington, D.C. 20307. [2]Smith, Kline, and French Laboratories, King of Prussia, PA 19406. [3]Repligen Corporation, One Kendall Square, Cambridge, MA 02139. [4]Hosp. of the U. of Pennsylvania, Philadelphia, PA 19104. [5]Laboratory of Tumor Cell Biology, NCI, NIH, Bethesda, MD, U.S.A.

Objectives: We described blocking of neutralizing activity (NA) of type-specific heterologous anti-sera by synthetic oligo-peptides from the RP135/136 region (a.a. 298-330) of gp120. The change of a single residue within this cysteine loop reduced blocking of NA. To further investigate the functional and immunological significance of this area of HIV-1 env, a panel of mutants were constructed.
Methods: Mutants were constructed in M13 containing a BglII - PvuII-BglII segment of BH10 envelope, inserted back into a phage clone containing the SalI-BamHI BH10 envelope insert, and the entire envelope cassette substituted for the the corresponding region of pHXB2gpt.
Results: The characteristics of mutant clones suggests that the integrity of the RP135 loop is important in viral infectivity, cell range, and syncytium formation, as well as determination of neutralizing phenotype. This this area does not appear to be involved in viral binding to CD4.

M.C.0.23 Three-dimensional Structure of the HIV-1 Protease and its Role in Virus Maturation

Navia, M.A., Fitzgerald, P.M.D., McKeever, B.M., Leu, C.-T., Heimbach, J.C., Herber, W.K., Sigal, I.S., Darke, P.L., and Springer, J.P. Merck Sharp & Dohme Research Laboratories, Rahway, NJ 07065 & West Point, PA 19486 USA

The structure of the HIV-1 protease has been solved by X-ray diffraction analysis, and is shown to be a dimer. Large regions of the HIV-1 protease monomer can be roughly matched to the N- and C- terminal domains respectively of the pepsin-like aspartyl proteases of known three dimensional structure, although significant differences do exist. The immediate active site region is assembled around the dimer interface with one characteristic Asp-Thr-Gly site sequence contributed by each monomer. An examination of the structure immediately suggests a mechanism for the auto-proteolytic excision of the protease from the gag-pol polyprotein fusion product on which it is synthesized. Further, an explanation for the central role of the protease in the control of the final assembly and maturation of the HIV-1 virus particle is suggested.

M.C.0.25 CONSTRUCTION OF AN INFECTIOUS MOLECULAR CLONE OF SIV$_{AGM}$ AND GENETIC COMPLEMENTATION WITH A REPLICATION-DEFECTIVE *ENV* MUTANT OF HIV-1 AND *POL* MUTANT OF SIV$_{AGM}$

Miura,T.*; Adachi,A.*; Shibata,R.*; Fukasawa,M.**; Hayami, Masanori*
*Institute for Virus Research, Kyoto University, Japan, **Institute of Medical Science, University of Tokyo, Japan.

Objective. To get a basic information for making a recombinant HIV-1 which can infect African green monkeys as an useful animal model system for AIDS.
Methods. Some full-length SIV$_{AGM}$ DNAs were cloned from the circular replicative intermediate DNA by linearization with one-cutting restriction enzyme. These clones were reconstructed to generate provirus form (pSAI21). The *env* defective mutant of HIV-1 (pNL-Kp) and *pol* defective mutant of SIV$_{AGM}$ (pSA-Ba) were constructed respectively. These constructs were transfected to COS-1 cell line. After 24 hr, the supernatants were inoculated to Molt4/cl8 cell line.
Results. Remarkable cytopathic effect (CPE) was observed and SIV$_{AGM}$ antigen was detected in inoculated Molt4/cl8 about a week after transfection with pSAI21. Weak CPE was observed when pSA-Ba and pNL-Kp were co-transfected, while no CPE was observed at all when pSA-Ba or pNL-Kp was used individually.
Conclusion. An infectious SIV$_{AGM}$ molecular clone was obtained and the genetic complementation with a replication-defective *env* mutant of HIV-1 and *pol* mutant of SIVAGM was suggested.

M.C.0.22 MOLECULAR ANALYSIS OF SINGLE CELL LYSIS BY HIV-1.

Sodroski, Joseph; Kowalski, M; Dorfman, T.; Bergeron, L.; Wojtkowsky, M.; Haseltine, W. Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA U.S.A.

Objective: To define regions of the HIV-1 envelope glycoproteins important for the cytopathic effects of the virus.

Methods: Mutations were introduced into the amino terminus of the gp41 transmembrane glycoprotein. The effects of the mutations on virus replication and cytopathic effect were determined.

Results: Mutations in the gp41 amino terminus resulted in either replication defective viruses or in viruses that replicated at levels approximately that of the wild-type virus. The latter viruses exhibited significant reductions in cytopathic effect in established human lymphocyte lines and in primary peripheral blood lymphocytes. Both syncytium formation and the lysis of single cells were attenuated in these mutants.

Conclusion: The amino terminus of the gp41 transmembrane glycoprotein, which has been previously shown to be important for the fusion of cell membranes during syncytium formation, is also involved in the lysis of single cells accompanying HIV-1 infection *in vitro*.

M.C.0.24 STRUCTURAL PATTERNS IN REGULATORY SEQUENCES OF HIV

Myers, Gerald; Linder, C.R. and Tung, C.-S.
Theoretical Division, Los Alamos National Laboratory, Los Alamos, N.M U.S.A.

Objective. To define DNA sequence-dependent structures for the TAR and NRE cis-acting regulatory elements.
Methods. Computer-assisted nucleotide sequence analysis--alignment and modeling of DNA tertiary structure--is correlated with mutational and biochemical results pertaining to the sequences for TAR and NRE.
Results. Two sequence-dependent consensus structures are identified for the HIV-1 TAR regulatory element at positions +16 and +37; hexanucleotide sequences corresponding to these structures have been shown by mutational and biochemical(i.e., footprinting) analyses to subtend the core of TAR. Different sequences yielding equivalent DNA structures are in HIV-2s at +18 and +33 and in SIVAGM at +17 and +39. The second of these two structures, responsive to cellular UBP-1 protein, is found in all lentiviral LTRs (EIAV, CAEV, Visna, FIV) at ca.+35 while the first of these structures is found only in HIVs and SIVs. Extension of this analysis to the NRE region of the LTR, now thought to be the cis-acting element for the NEF regulatory function, again reveals the role of DNA tertiary structure in HIV regulation. Sequence-dictated microcurvature of the DNA may be essential to this region of the LTR.
Conclusion. Transactivation of HIVs and SIVs partly entails indirect (versus direct) readout of the DNA by proteins; site-directed mutagenesis of HIVs and related retroviruses should have this phenomenon in mind. The results suggest ways to uncouple the RNA effects and DNA effects pertinent to transactivation.

M.C.0.26 EXPERIENCE WITH EIGHT HIV-VACCINE TRIALS IN CHIMPANZEES

Eichberg, Jorg W., Southwest Foundation for Biomedical Research, San Antonio, Texas, USA.

Objective. To test the efficacy of various HIV-vaccines in chimpanzees.
Methods. The following HIV vaccine candidates were employed to actively or passively vaccinate 27 chimpanzees: 1. synthetic peptide (735-752), 2. vaccinia-env recombinant, 3. recombinant gp120 expressed in mammalian cells, 4. HIV-immune globulin (HIVIG) prepared from HIV-1 positive asymptomatic people, 5. recombinant gp160 peptide (350-674), 6. vaccinia-gag recombinant, 7. a combination of vaccinia gag and env recombinants 8. idiotypic antibodies (cocktail of anti-CD4s).
Results. Cell-mediated immunity in immunized animals, as assayed by specific lymphocyte blastogenesis or cytotoxicity, was only detected in vaccine trials 2,3,6,7. While all vaccines induced humoral antibodies as detected by Elisa and/or Western blotting, only passive immunization (trial 4) conferred significant neutralizing antibodies. All immunized and control chimpanzees that were challenged (trials 1-4) were not protected, i.e. HIV could be isolated and/or seroconversion was documented. Due to the experience gained in trials 1-4 and the poor neutralizing antibody response it was decided that vaccine candidates 5-7 did not warrant a challenge with live HIV. The experiment with vaccine candidate 8 is still in progress.
Conclusion. Eight HIV vaccines tested in 27 chimpanzees did either not confer protection or did not warrant challenge with live HIV or are in progress.

Pathogenèse (partie 2)

M.C.O.27

INTESTINAL HIV INFECTION IN AIDS AND ARC: CORRELATION WITH TISSUE CONTENT OF P24 AND INTERLEUKIN-1 BETA

Reka, Sahar*; Borcich, A*; Cronin, W**; Kotler, DP*.
*St. Luke's-Roosevelt Hospital Center, Columbia University, New York, NY, USA
**Lenox Hill Hospital, New York, NY, USA.

Objectives. To localize and quantitate HIV in the rectal mucosa of patients with AIDS and ARC: to correlate HIV expression with the occurrence of diarrhea, the tissue content of interleukin-1 beta (IL-1) and with lymphocyte numbers in peripheral blood.
Methods. Rectal biopsies from 30 AIDS and 18 ARC patients were studied by quantitative p24 ELISA (Coulter) of homogenates, immunoperoxidase studies (IP) of tissue sections using monoclonal anti-p24 (Dupont), and by quantitative IL-1 ELISA (Cistron).
Results. ELISA assays demonstrated p24 in 67% of AIDS and 89% of ARC. Tissue p24 was higher in ARC than AIDS (368±167 v 96±37 pg/mg prot, p=0.06) while serum p24 was higher in AIDS than ARC (65±25 v 9±4pg/ml, p=0.08). In ARC, tissue p24 was higher in patients with diarrhea (408 v 131, NS). IP localized p24 to lamina propria mononuclear cells in 72% as well as intraepithelial lymphocytes in 59% and epithelial cells in 52%. Tissue IL-1 was higher in AIDS and ARC (217±88, 253±83 pg/mg prot) than in normal controls (11±8). There were no correlations between tissue p24 and CD4, CD8 or total lymphocytes in blood. An infectious cause was found in 15/18 AIDS but only 1/9 ARC patients with diarrhea.
Conclusions. Intestinal HIV infection is common in AIDS and ARC. In ARC, tissue HIV content is associated with diarrhea, and with increased tissue IL-1. HIV may be a direct cause of diarrhea in ARC.

M.C.O.28

ACTIVATED ASTROCYTE-CONDITIONED MEDIUM STIMULATES HIV-1 EXPRESSION IN A CHRONICALLY INFECTED PROMONOCYTE CLONE

Vitković, Ljubiša; Kalebic, T.; and Fauci, A.S. LIR, NIAID, NIH, Bethesda, MD. U.S.A.

Objective. To test the hypothesis that an interaction between chronically HIV-infected monocytes and reactive astrocytes may lead to the activation of HIV-1 in brain.
Methods. A human promonocytic cell line infected with HIV-1 (clone U1.1.5) were grown in the presence of media conditioned by growth of primary rat cortical astrocytes in the presence or absence of lipopolysaccharide (LPS; 10 ug/ml). HIV-1 expression was assessed by measuring reverse transcriptase activity. Tumor necrosis factor alpha (TNF_{α}) was measured in astrocyte-conditioned media with biological cytotoxicity and enzyme-linked immunosorbent assays.
Results. The media conditioned by growth of astrocytes and LPS-activated astrocytes induced 1.5-fold and 4.0-fold, respectively, the expression of HIV-1. LPS alone, media conditioned by growth of the uninfected parental cell line of U1.1.5 (U937) or mouse fibrosarcoma cells (WEHI 164, clone 13) had no effect on viral expression. The magnitude of induction was dose-dependent. TNF_{α} was detected in astrocyte-conditioned media and was neutralized by specific antibody. Time course and dose-dependence of the induction were similar to those observed when either human or mouse (recombinant) TNF_{α} were added to growing U1.1.5 cells.
Conclusion. These results suggest that astrocytes are capable, through secreted factor(s), of inducing HIV-1 in chronically infected monocytes and that one of the inducers is TNF_{α}.

M.C.O.29

SPERM MEDIATED TRANSFER OF HIV INTO TARGET CELLS: ROLE IN AIDS TRANSMISSION.

Veronica E. Miller and Virginia L. Scofield. Dept. Microbiology and Immunology, UCLA, Los Angeles, California USA 90024

We have previously reported that human sperm bind to and penetrate human lymphocytes. This interaction is mediated by the HLA-DR and -DQ ligands on target cells and a CD4-like receptor on sperm. We have identified two mechanisms of sperm entry into lymphocytes and HLA-DR transfected murine fibroblasts: 1) endocytosis, where electron micrographs show sperm clearly inside endocytic vesicles, and 2) direct fusion between sperm and target cell membranes, in which case sperm heads are visible inside the cytoplasm with no surrounding membrane. We have subsequently shown that normal sperm, when preincubated with HIV, bind to and penetrate $CD4^+$ $HLA\text{-}DR^-$ cells, and that in this case, the ligand on the target cells is the CD4 molecule.

We have proposed that the event of somatic cell penetration by sperm is one mechanism for AIDS transmission by semen. According to this model, HIV transported by sperm would have access to non-$CD4^+$ cells, and if penetration is by direct fusion, the virus would be directly exposed to the cytoplasm. In support of this model, we have evidence that sperm isolated from AIDS patients is capable of infecting activated PBL cultures *in vitro*. Two different separation techniques were used: 1) the swim-up method, where motile sperm are allowed to swim-up from a pellet into culture medium, and 2) centrifugation through 90% Percoll. Although a substantial number of round cells (immature germ cells) were visible in some of these preparations, staining with anti-CD45 antibodies revealed no lymphocyte contamination. In addition, using immunogold-electron microscopy we detected the presence of gp120 antigens on AIDS patients' sperm cell surfaces. We are currently investigating the possibility of HIV transmission by normal donor sperm and HIV combinations.

M.C.O.30

INVESTIGATION OF THE SUSCEPTIBILITY OF THYMIC PRECURSOR T CELLS TO INFECTION BY HIV-1

Pereira, Rosemarie*+; Mugeyre, M.T.*; Aubert, C*; London, J.*‡; Orden, S* and Barré-Sinoussi, F*.
*Institut Pasteur, Paris, France, +Institute of Medical and Veterinary Science, Adelaïde, Australia, ‡Université Paris 7, Paris, France.

Objective. Infection of precursor lymphoid cells could be one of the possible causes of the lymphopenia observed in HIV-infected individuals. Studies showing that bone-marrow cells are susceptible to infection by HIV-1 give support to this hypothesis, but, the nature of these cells is unknown. Our aim was to evaluate the infectibility of immature thymic cells by HIV-1 and to determine the phenotype of permissive cells.
Methods. FACS analysis, cell depletion using antibody-coated magnetic beads (A-MB), immunohistochemistry and in situ hybridisation (ISH).
Results. We have successfully infected total thymocytes from normal infants up to 12 months of age, with HIV-1. Ficoll gradients used to enrich for immature thymocytes have yielded five fractions each expressing CD1, CD3, CD4 and CD8 antigens to varying degrees and being equally infectible by HIV-1. In order to purify immature thymocytes, we used A-MB to deplete $CD4^+8^+$, $CD4^+8^-$ and $CD4^-8^+$ cells. We obtained a 95-98 % pure $CD4^-8^-$ population which was successfully infected by HIV-1 as determined by ISH (37.9 % positive cells) and appearance of RT activity in 10 day culture supernatants.
Conclusion. Our data suggest that immature $CD4^-8^-$ thymic cells are susceptible to infection by HIV-1. The phenotype of these permissive cells is under investigation.

M.C.O.31

TRANSIENT EXPRESSION OF THE HIV-1 GENOME DURING INFECTION OF THE DEVELOPING HUMAN NERVOUS SYSTEM

Kunsch, Charles and Wigdahl, B.
Department of Microbiology and Immunology, The Pennsylvania State University College of Medicine, Hershey, PA 17033 USA

Objective. To examine the virus-specific events associated with HIV-1 infection of primary neural cell populations isolated from the developing human peripheral nervous system.
Methods. HIV-1-infected human fetal neural cells derived from the dorsal root ganglia (DRG) were examined for the production of virus-specific protein and nucleic acid utilizing immunohistochemistry and hybridization techniques. Transmission electron microscopy (TEM) was used to examine cellular ultrastructure after infection by HIV-1 and the production of infectious HIV-1 was monitored by cocultivation and reverse transcriptase (RT) assays.
Results. We have previously demonstrated that human fetal DRG glial cells are susceptible to HIV-1 infection and express HIV-1 gag (p17 and p24) antigens. HIV-1-specific RNA detected in DRG neural cells by 2 hr postinfection (PI) increases in quantity to a maximal level between 2 and 3 days PI and declines thereafter to minimally detectable levels by 16 days PI. The regions of the HIV-1 genome which are being actively transcribed during acute infection were examined using HIV-1 gene-specific probes. Cocultivation and RT assays indicate that within 4 weeks after infection of the DRG neural cells by HIV-1, no infectious HIV-1 was produced in the infected cells even at time points when considerable quantities of HIV-1-specific RNA and protein were synthesized. Although TEM analyses have suggested the absence of intracellular viral particles, highly electron-dense inclusions in the cytoplasm of HIV-1-infected DRG glial cells were observed. The nature of the cytoplasmic inclusions in relationship to the apparent abortive infection is currently under investigation.
Conclusion. These results suggest that HIV-1 infection of human fetal DRG glial cells results in transient expression of the viral genome terminating in an abortive and possibly latent infection.

M.C.O.32

HIV gp41 synthetic peptides inhibit LAK activity

Cauda R., Tumbarello P., Ortona L., Kanda P., Chanh T.C., Kennedy R.C.
Dept. of Infectious Diseases Catholic University Rome ITALY
Dept. of Virology and Immunology Southwest Foundation San Antonio Tx.USA

Objective. Previous studies from our group have demonstrated that HIV gp 41 synthetic peptides inhibit natural killer cell activity of normal subjects interfering with the post-binding phase. (Cauda R. et al. Cell. Immunol.115, 57-65,1988). Aim of this work was to demonstrate the effect, if any, of HIV gp 41 synthetic peptides on the lymphokine activated killer cell activity (LAK), which is compromised in HIV infected patients. LAK cell activity is a functional activity induced by long term incubation of peripheral blood lymphocyte with recombinant interleukin 2 (rIL2). The cells acquire the ability to lyse cell lines which are usually resistant to normal NK cell activity. LAK cell activity seems to be predominantly due to Fc γ^+ receptor cells and in a lesser extent to CD3 γ/δ^+ cells.
Methods. Two different HIV synthetic peptides corresponding to amino acid sequences 735-752 and 846-860, were synthetized. Two different synthetic peptides (cT and mT from SV-40) were used as controls. PBMC, obtained from normal subjects were cultured (at a concentration of $1x10^6$/ml) in RPMI 1640 medium with FCS for 3 days at 37° C in 5% CO_2 with 100 U of rIL2 and in presence of the HIV synthetic transmembrane peptides (or control peptides) and subsequently used as effector cells. Target cell line used was HL 60 cell line. The cytotoxicity assay was a 4-h ^{51}Cr release and the effector/target cell ratio was 40:1, 20:1, 10:1, 5:1 2.5:1.
Results. LAK cell activity was significantly inhibited at all the effector:target cell ratios tested in presence of the two synthetic peptides of 18 and 15 amino acids in length homologous to sequences 735-752 and 846-860 of HIV gp 160. On the contrary the control peptides did not exerted any significant inhibition. Results in table are expressed as % specific release.

	40:1	20:1	10:1	5:1	2.5:1
735-752 peptide	15	9	4	2	<1
846-860 peptide	18	10	7	4	<1
cT peptide	78	54	35	24	18
without peptides	80	55	36	26	20

Conclusion. HIV synthetic peptides exhibit a profound inhibition of both NK and LAK activity probably acting on the lytic capability of LAK cells. The long term effect of this inhibition could be the increased frequency of viral infections and the development of neoplases which characterize the natural history of AIDS.

Virologie (partie 1)
Virology (Part 1)

T.C.0.1

DESIGN AND ACTIVITY OF A NOVEL CLASS OF NUCLEOSIDE ANALOGS EFFECTIVE AGAINST HIV-1.

Belleau, Bernard*; Dixit, D.*; Nguyen-Ba, N.**; Kraus, J.-L.*.
*Institut Armand-Frappier, Université du Québec, Laval, Que., Can.; **IAF BioChem International Inc., Laval, Que., Can.

Objective: To replace the pentose of nucleoside analogs by isosteric rings in which the 3'-carbon = an S or O atom and to test these cpds. to block HIV replication *in vitro*.
Methods: Synthetic strategies were used to make intermediates with a 5'-hydroxymethyl group in the desired steric relationship with base substituents. The *de novo* syntheses led to mixtures of *cis*- (natural) and *trans*- (unnatural) isomers which were separated and fully characterized.
Results: Two cpds., both carrying a cyt substituent, were generated on a scale which allowed extensive biological evaluation. The best analog, NGPB-21, having the "natural" *cis*-configuration was very effective *in vitro* as an anti-HIV-1, its potency equivalent to AZT in all assays, as well as an improved therapeutic index. Another analog, DDIII30A (unnatural *trans*-configuration), had a surprisingly good *in vitro* profile. Some structure-activity relationships will be discussed briefly.
Conclusion: Novel compound NGPB-21 is a drug candidate for AIDS and is less toxic than AZT. Supported by an NSERC/IAF BioChem-Industrial Research Chair (Bernard Belleau).

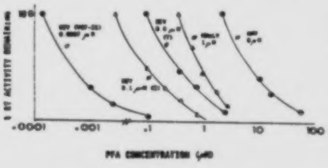
T.C.0.2

DIFFERENTIAL SENSITIVITY OF WILD TYPE AND RECOMBINANT HIV-REVERSE TRANSCRIPTASE TO INHIBITION BY FOSCARNET.

Marilyn M. Lightfoote and J.Martyn Bailey.
The George Washington University School of Medicine and Health Sciences
Washington, D.C. 20037 U.S.A.

The recombinant reverse transcriptase from HIV-1 cloned into the vaccinia vector VCF-21 (Moss) was expressed in monkey kidney cells and purified from culture supernatants by conventional chromatographic procedures. The kinetic characteristics for inhibition of the recombinant enzyme by phosphonoformic acid (Foscarnet) were compared to that of the wild type HIV-RT and RT's of other retroviruses. Incorporation of ^{3}H TTP directed by a poly rA dT_{m} template was inhibited with an IC_{50} of only 0.0007 µM compared to 0.4 µM for the wild type HIV-RT (Figure). K_m for TTP substrate, however was not significantly different. Sensitivity of a recombinant HIV-RT expressed in E.Coli is reportedly the same as that of wild type RT. Properties of the VCF-21 RT construct expressed in different mammalian cells were compared. The results indicate that post transcriptional processing of the vaccinia RT construct may vary in different eucaryotic cell types and can give rise to HIV-RT variants with markedly enhanced sensitivity to Foscarnet.

SENSITIVITY OF VIRAL REVERSE TRANSCRIPTASES TO INHIBITION BY PHOSPHONOFORMATE



T.C.0.3

INHIBITION OF HIV-1 INDUCED SYNCYTIA FORMATION BY MONOCLONAL ANTIBODIES TO THE MEMBRANE ADHESION PROTEIN CD18.

Valentin A(1), Patarroyo M(2), Asjö B (1).
1. Department of Virology and 2. Department of Immunology, Karolinska Institute, Stockholm, SWEDEN

OBJECTIVE To study the partecipation of the leukocyte adhesion glycoprotein CD18 in HIV induced syncytia formation.
METHODS U937 clone 16 cells were pretreated with monoclonal antibodies (Mab) 60.3 resp. IB4 directed to the CD18 or Mab to major histocompatibility complex class I (MHC-I). Treated and control cells were infected with the HTLV-IIIB strain of HIV and grown in presence or absence of the respective Mab. Viral replication was monitored by reverse transcriptase (RT) activity, immunofluorescence (IF) and syncytia formation.
RESULTS HIV infection of U937 clone 16 cells resulted in extensive viral replication as demonstrated by high RT activity of culture medium, high percentage of IF positive cells and pronounced syncytia formation leading to cell death. In contrast, cells pretreated with Mabs to CD18 yielded cell cultures with no signs of cell aggregation or syncytia formation, low percentage of infected cells, low RT activity and high cell viability for several weeks. The specificity of the inhibition of HIV induced syncytia formation was demonstrated by addition of MHC-I Mab. No difference in cytopathic effect was observed between this culture an the control.
CONCLUSION Mabs directed to the leukocyte adhesion glycoprotein CD18 efficiently block HIV induced syncytia formation and cell death. Our results also suggest that intercellular adhesion contributes to and enhances spreading of the viral infection in vitro and possibly in vivo.

T.C.0.4

STRUCTURE AND FUNCTION OF HIV-1 REVERSE TRANSCRIPTURE (RT)

B.A.Larder, D.Lowe, Dorothy J.M.Purifoy, M.Tisdale, G.Darby, D.K.Stammers, et al, UNITED KINGDOM

Objective: To determine important structural features of the HIV-RT.
Methods: A variety of genetic manipulation techniques including site directed mutagenesis has been used to create a large number of variants of the HIV RT. These include enzymes with modified amino-acid sequences, with portions of the enzyme deleted (at N or C terminus or internally), or with additional amino-acids added. These mutant enzymes have been used to delineate the function of specific regions of the enzyme.
Results: Deletion of the C Terminal region of the enzyme has previously been shown to remove part but not all of the enzymes activity. We further define this region and further delineate a region of the enzyme that can be deleted without major loss of enzyme activity. Site specific mutants have been generated which alter the sensitivity of the enzyme to the anti-HIV drugs AZT and PFA. To determine the effect of such mutations on the ability of HIV to replicate proviral constructs were made encoding the mutant RT genes. On transfection of these constructs into T-cells two were found to replicate. These viruses showed decreased sensitivity to PFA, demonstrating infectious PFA resistant virus can arise *in vitro*. Finally, we have attempted to crystallise each of the variants to get better ordered crystals of RT. An up-to-date progress report on how the mutant enzymes crystalise will be given.
Conclusion: Mutational analyses have been successfully applied to determine functionally important regions of the HIV RT.

T.C.0.5

IDENTIFICATION OF SEVERAL SPECIES OF HIV-1 MAJOR CORE PROTEIN : PRODUCTION AND CELL-SURFACE EXPRESSION

Laurent,A.G., Krust, B., Rey, M.A., Montagnier, L M. and Hovanessian, A.G.
Unité d'Oncologie Virale, Institut Pasteur, Paris 15, France.

Objective : Characterization of HIV-1 gag gene product p25 by two dimensional gel isoelectrofocusing analysis.
Results : The p25 detectable in HIV-1 infected cells is composed of four species designated as a, b, c and d with isoelectric points : 6.8, 6.6, 6.5 and 6.3, respectively. Species b and d are the phosphorylated forms of species a and c, respectively. The two most acidic species c and d have a slightly slower electrophoretic mobility in polyacrylamide gels compared to the species a and b. All four species of p25 could be immunoprecipitated by polyclonal and monoclonal antibodies but only species a and b could be identified by electrophoretic transfer immunoblot assay using these same antibodies. Thus once p25 is denatured, then species c and d cannot be identified by polyclonal or monoclonal antibodies.
Pulse chase experiments indicated that all four species of p25 are produced at the same time after the synthesis of p55 but their subcellular localization is different.Only species a and b are recovered with the virus particles whereas species c and d and a proportion of species a and b are secreted by virus producing cells. In addition to these results, lactoperoxydase catalyzed iodination of the cell surface was employed to show that the four species of p25 are expressed on HIV-1 infected cells.
Conclusion : These different observations suggest that there might be distinct processing pathways for the production of species a,b compared to species c,d.

T.C.0.6

GAG AND GAG-POL PROTEIN PRECURSORS MADE FROM A SV40 LATE REPLACEMENT VECTOR ARE PROPERLY PROCESSED AND ASSEMBLED INTO PARTICLES

Smith, Alan J.; Hammarskjöld, M.-L.; and Rekosh, D.; Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

The expression of the HIV-1 gag and pol genes has been studied using fragments of the BH10 clone of HIV inserted into a SV40 late replacement vector. An initial construct containing the entire coding regions of *gag*, *pol* and *vif* produced only minute amounts of the gag precursor (p55). However, high level expression was obtained when an additional sequence from the *env* gene (the rev-responsive element) was inserted 3' of *vif* in the correct orientation, and rev was provided in trans from a second vector. Western blot analysis of transfected cells showed the presence of large amounts of both gag and gag-pol precursors as well as all of the expected cleavage products. In addition analysis of the culture medium showed the presence of particle-associated reverse transcriptase activity. Experiments are presently underway to determine whether envelope proteins, expressed from a separate vector, and virus-specific RNA are associated with these particles.

Mécanismes de pathogenèse des rétrovirus humains
Mechanisms of Pathogenesis of Human Retroviruses

T.C.0.7

VARIANTS OF HIV RESISTANT TO ZIDOVUDINE (AZT)

Larder, Brendan A.*; Kemp, S.D.*; Darby, G.* and Richman, D.D.**.
*Molecular Sciences Dept., Wellcome Research Laboratories, Beckenham, Kent, U.K. **Infectious Diseases Dept., V.A.Medical Center, San Diego, U.S.A.

Objective. To investigate whether prolonged exposure of HIV to zidovudine in patients leads to selection of resistant variants.
Methods. HIV was isolated from PBLs prepared from untreated and zidovudine-treated individuals and propagated in MT-2 cells. Zidovudine sensitivity was assessed by plaque-reduction in a HeLa cell line (HT4-6C) expressing the human CD4 gene.
Results. Infection of HT4-6C cells with HIV results in formation of plaques (foci of multinucleated giant cells) allowing precise determination of drug-sensitivity. Isolates from untreated individuals showed very similar sensitivity to zidovudine (mean ID$_{50}$ 0.03µM; range, 0.01-0.05µM). However, most isolates from patients with AIDS or ARC treated for 6 months or more showed decreased sensitivity characterized by increase in ID$_{50}$ or ID$_{95}$ values (or both). Several isolates showed 100-fold increases in ID$_{50}$, although these were sensitive to all other drugs tested except AZdU. The resistance mechanism is being investigated by analysis of cloned reverse transcriptase genes. The sensitivity of HIV isolated from asymptomatic individuals during therapy is also being determined.
Conclusion. Zidovudine-resistant variants of HIV can be isolated from patients with AIDS or ARC after prolonged therapy. At present the clinical significance of this observation is unclear.

TRANS-REGULATION OF HIV-1 GENE EXPRESSION

Michael H. Malim and Bryan R. Cullen.
Howard Hughes Medical Institute, Departments of Medicine and Microbiology and Immunology, Duke University Medical Center, Durham, NC 27710 USA.

This presentation will briefly address the physiological role of the regulatory proteins encoded within the genome of HIV-1, focusing particularly on the viral rev gene product. The Rev protein is required for expression of the viral structural gene products and, hence, for viral replication. I will review data demonstrating that rev functions post-transcriptionally to modulate the transport of HIV-1 mRNAs from the infected cell nucleus to the cytoplasm, where translation into viral proteins occurs. In addition, I will review recent data demonstrating that the rev protein contains two discrete functional domains. One of these is required for the specific interaction of rev with its viral RNA target sequence. The second is required for the subsequent activation of viral RNA expression. These results will be discussed with reference to possible targets for therapeutic intervention into AIDS.

T.C.0.11

EXPRESSION, PURIFICATION, STRUCTURE, ACTIVITY AND SUBSTRATE SPECIFICITY OF THE HIV-1 RETROVIRAL PROTEASE.

Debouck, Christine; Deckman, I.; Malinowski, J.; Meek, T.; Moore, M.; Strickler, J.; et. al.
Smith Kline& French Laboratories, King of Prussia, PA 19406, USA.

Objective. The gag and pol coding region of HIV-1 is translated into large precursors that are cleaved by a protease encoded by the virus and that is unique and essential. Our goal is to develop specific inhibitors of this enzyme that will block the maturation and infectivity of the virus without interfering with the host physiology.
Methods/Results. The HIV-1 protease was expressed as a precursor and in its mature form in various E. coli strains and shown to specifically cleave its own gag-pol substrate in vivo as well as heterologous substrates containing appropriate cleavage sites. This system was used to identify residues in the enzyme that are essential for its activity. The enzyme was purified to homogeneity and its structure and enzymatic activity characterized. A simple peptidolytic in vitro assay was developed to be used to screen natural products and rationally designed compounds for inhibitory activity.
Conclusion. Asp-25 and Cys-95 are residues critical for the HIV-1 protease activity. The enzyme is an aspartyl-protease and behaves as a dimer in solution. Peptides with inhibitory activity were identified in an in vitro assay for the enzyme.

This work was supported in part by NIH grants AI24845 and GM39526.

TUMOR NECROSIS FACTOR-ALPHA ACTIVATES HIV EXPRESSION IN A CHRONICALLY INFECTED T CELL CLONE THROUGH INDUCTION OF NUCLEAR FACTOR BINDING TO NF-κB SEQUENCES

Ella J. Duh*, Wendy J. Maury*, Thomas M. Folks**, Anthony S. Fauci*, and Arnold B. Rabson*
*NIAID, NIH, Bethesda, MD, **CDC, Atlanta, GA USA

Objective. To describe the molecular events by which TNF-α activates HIV expression.
Methods. The ACH2 cell line is a clonal cell line derived following infection of A3.01 T cells with HIV-1. ACH2 cells are chronically infected with HIV and contain a single integrated HIV provirus whose expression can be augmented by TNF-α treatment. Steady state HIV RNA levels were studied by slot blot hybridization, and activation of HIV transcription was analyzed by nuclear run-on assays. Gel retardation assays employing P-32 labeled oligonucleotides were used to study the induction of nuclear proteins binding to the HIV long terminal repeat. Transfections of wild type and mutant HIV LTR-CAT plasmids into A3.01 T cells were performed to identify LTR sequences responsible for activation.
Results. TNF-α treatment of ACH2 cells resulted in an increase in steady state levels of HIV RNA and HIV transcription. Gel mobility shift assays demonstrated that the transcriptional activation of the HIV LTR by TNF-α was associated with the induction of a nuclear factor(s) binding to the NF-κB sites in the LTR. Deletion of the NF-κB sites from the LTR eliminated activation by TNF-α in T cells transfected with plasmids in which the HIV-LTR directed the expression of the CAT gene.
Conclusion. TNF-α appears to activate HIV RNA and virus production by ACH2 cells through the induction of transcription activating factors that bind to the NF-κB sequences in the HIV LTR.

T.C.0.13

RNA SPLICING EVENTS DETECTED IN EARLY IN VITRO HIV INFECTION USING THE POLYMERASE CHAIN REACTION (PCR)

Klotman Mary E., DeRossi A., Buchbinder A. and Wong-Staal F., Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Md. U.S.A.

Objectives: The HIV genome codes for at least six additional regulatory gene products along with the gag, pol and env products. The complexities of this 9 kb virus are in part due to the regulation of a series of splicing events during the production of these gene products. We studied the early splicing events that occur after infection of H9 cells with purified HIV to determine the sequence of events.

Methods: RNA was extracted from infected cells at a series of time points ranging from one hour after viral absorption to forty-eight hours. Antisense primers and AMV reverse transcriptase were used to make cDNA which was amplified by PCR using sets of oligonucleotide primers designed to detect specific splicing events. The regulatory primers were chosen from within the 2nd and 3rd exon flanking the splice donor-acceptor sites at nucleotides 6044 and 8378. The envelope primers were from within the first and second exon and flanked the splice donor-acceptor sites at nucleotide 703 and 5975 respectively.

Results: The splicing between the first and second coding exons of the regulatory genes tat, rev and nef could be detected within hours after infection and appeared before splicing of the envelope exons which occurred within six hours of infection. Standard Northern blotting did not detect these mRNAs at the early time points.

Conclusion: mRNA splicing occurs very early in infection of H9 cells with HIV. Splicing of regulatory exons precedes splicing of mRNA coding for structural gene products.

T.C.0.14

POTENTIAL BIOLOGICAL SIGNIFICANCE OF A SECONDARY RNA START SITE WITHIN THE HIV-LTR

Mosca, J.D.*+; Bednarik, D.P.*
*The Henry M. Jackson Foundation, Retrovirology Laboratory, Rockville, MD, USA; +The Johns Hopkins Oncology Center and Dept. of Immunology and Infectious Diseases, Baltimore, MD, USA.

Objective: The aim of the present study was to determine the biological significance of a secondary RNA start site within the HIV-LTR.
Methods: While studying the ability of the HIV-encoded tat/III gene product and heterologous viruses to transactivate the HIV-LTR, we noticed that S1 nuclease analysis of RNA consistently gave two specific size RNA transcripts. Using S1 nuclease analysis of RNA obtained in permanent and transient assays of three HIV-LTR/reporter gene constructions, HIV-LTR deletions, provirus transfections, HIV infection of T and Monocyte primary cells, in addition to PCR analysis, we have demonstrated that indeed RNA initiates from this secondary site.
Results: S1 nuclease mapping has localized the site of the secondary RNA start to 80 base pairs downstream from the primary RNA start site. RNA analyses show that whereas the HIV-LTR containing 167 nucleotides 5' from the primary RNA start site results in RNA expression from both start sites, an HIV-LTR deletion containing only 45 nucleotides results in RNA expression only at the secondary start site. Provirus transfections and HIV infections suggest the existence of more than one RNA transcript for the HIV-encoded tat/III gene product, possibly due to RNA initiation at the secondary site. We are using PCR analysis to attempt to further map and to ascertain the biological significance of a secondary start site in HIV regulation.
Conclusion: These data support the possibility that the existence of a secondary RNA start site could play a significant role in HIV gene expression and replication.

T.C.0.15

REGULATORY ELEMENTS IN THE LTR (HIV-1) RESPONSIVE TO GLUCOCORTICOID STIMULATION

Sperl, B.*; Helzig, V **; Zagury, J.F.*; and Zagury D.*
*Université Pierre et Marie Curie, Paris, France. **University Hamburg GDR

Within the LTR of HIV-1 provirus we have identified two hormone responsive elements (HREs) corresponding to the TGTTCT sequence identified as the glucocorticoid receptor binding element within the LTR or MMTV (mouse mammary tumor virus).
We have used an LTR (HIV-1)-CAT construct to transfect infected (H9V3) and non infected H9 cells. Four hours before harvest the two cell types were divided into two and one half treated with hydrocortisone (10-7M). The cells were harvested, washed and the CAT activity measured. In eight repeat experiments an increased (50%) expression of the CAT gene in the presence of the glucocorticoid cells has always been observed in H9V3, but no effect of the steroid has been measured in the non infected cells. Double transfection of LTR(HIV-1)-TAT and LTR (HIV-1)-CAT into non infected H9 cells results in a cell population in which the CAT gene was responsive to glucocorticoid stimulation. We have further shown, using cells transfected with a mutant LTR(HIV-1) promoted CAT that only one of the steroid HREs is required for the glucocorticoid response. Our results are discussed in relation to the well characterised MMTV-LTR system and to the well established role of glucocorticoids in HIV-1 viral expression.

T.C.0.16

MECHANISM OF HIV-1 INFECTION OF MONONUCLEAR PHAGOCYTES

O'Brien, William A.; Koyanagi, Y. and Chen, I.S.Y.
UCLA School of Medicine, University of California, Los Angeles CA, USA

Objective. To investigate mechanisms of mononuclear phagocyte infection by macrophage-tropic strains of HIV-1.
Methods. Two distinct HIV-1 isolates with differing ability to productively infect mononuclear phagocytes *in vitro* were molecularly cloned and compared at the sequence level. Kinetics of virus infection were measured in mononuclear phagocytes following treatment with granulocyte-monocyte colony-stimulating factor (GM-CSF). Fragments of the HIV-1 LTR linked to the indicator gene, CAT (chloramphenicol acetyltransferase), were transfected into primary blood-derived mononuclear phagocytes +/-GM-CSF to identify sequences necessary for GM-CSF activation.
Results. The complete nucleotide sequence of two HIV-1 isolates from the same individual having different tropism for mononuclear phagocytes show a sequence difference of 3%. The macrophage-tropic virus replicates to high titers in these cells, and its production is further enhanced by GM-CSF treatment. Sequences in the HIV-1 transcriptional enhancer region necessary for GM-CSF activation were identified. These sequences are distinct from the NF-κB binding sequences of the LTR.
Conclusion. Related viruses may have biologic differences. Sequences in the HIV-1 LTR neccessary for GM-CSF activation in mononuclear phagocytes are distinct from those necessary for virus replication following T-cell activation.

Pathogenesis (Part 3)

T.C.0.17 THE ROLES OF THE VPX AND VPR GENES IN SIMIAN IMMUNODEFICIENCY VIRUS LIFE CYCLE

Xiao-fang Yu; Essex, M.; Lee, T.H. Harvard School of Public Health, Boston, MA, USA

Objective. To study the function of SIVmac vpx and vpr genes in viral life cycle.

Method. The approach of site-directed mutagenesis was used to introduce mutations in the vpx and vpr genes of SIVmac. The phenotype of the wild type and mutant viruses were analyzed by monitoring reverse transcriptase activity, cytopathogenicity, morphological changes and the expression of viral genes.

Results. The vpx mutant has an increased cytopathogenicity when compared with the wild type virus. Persistant cell killing in some human cells was observed only with the vpx mutant. The increased cytopathogenicity of the vpx mutant was not due to increased synthycia-forming ability or increased infectivity. The vpr gene appears to be dispensable for the viral replication in vitro. Sortly after infection, the vpr mutant had a different growth rate from that of the wild type virus.

Conclusion. Mutations introduced into the vpx and vpr genes appear to have effects in the SIVmac life cycle. These effects were not readily scored in all the cell lines studied. The existance of vpx and vpr genes in some closely related retroviruses but not in others may suggest that the function of these two genes is spieces and/or cell type dependent.

T.C.0.18 EFFECT OF RECOMBINANT SOLUBLE CD4 (rCD4) ON INFECTION OF NON-LYMPHOID CELLS BY HIV-1.

Ikeuchi, Kenji; Byrn, R.A.; Scadden, D.; Goldring, S. and Groopman, J.E.
New England Deaconess Hosp., Harvard Medical School, Boston,MA U.S.A.

Objective. To test the blocking effect of rCD4 on non-lymphoid cell infection with HIV-1 IIIB.
Methods. Adherent L132 (human embryonic lung epithelial cells), U138MG (human glioblastoma cells), F13 (human foreskin fibroblast cells) and MRC5 (human fetal lung fibroblast cells) were inoculated with HIV-1 IIIB. Residual virus was removed by trypsinization and vigorous washing. After more than 10 days in culture, uninfected H9 indicator cells were added. For blocking experiments, rCD4 or Leu3a was added to the cultures.
Results. Virus production in L132 and U138MG cells was directly detected by immunofluorescence and reverse transcriptase activity. Infection of MRC5 was detected only after co-cultivation with H9 cells. No infection of F13 was detected. Recombinant CD4 and Leu3a blocked infection of L132 and U138MG with HIV-1 IIIB. These agents also blocked the transfer of infection from infected L132 and U138MG cells to H9 cells.
Conclusion. L132, U138MG and MRC5 can be infected with HIV-1 IIIB by a CD4-dependent mechanism. Recombinant CD4 may be effective as an anti viral agent for non-lymphoid cell types.

T.C.0.19 GENETIC ANALYSIS OF SEQUENTIAL HIV-1 ISOLATES FROM AN INFECTED LAB WORKER.

Kong, Lily Ing*; Taylor, M.E.*; Waters, D.**; Blattner, W.A.***; Hahn, B.H.*; and Shaw, G.M.*
*University of Alabama at Birmingham, Birmingham, Alabama, USA; **Program Resources, Inc., Frederick, Maryland, USA; ***National Cancer Institute, Bethesda, Maryland, USA.

To better understand the nature of genetic and antigenic variation of HIV-1 in humans, virus was sequentially isolated and characterized from a previously reported (Science 239:68, 1988) lab worker (LW) infected by the H9/HTLV-IIIb strain of virus. Between 9/4/85 and 5/18/88, 7 HIV-1 isolates were established in 3 independent laboratories from the peripheral blood mononuclear cells (PBMC) of LW by co-cultivation with PBMC of normal donors. Southern blot hybridization patterns of all 7 LW isolates were indistinguishable from each other and from a component of the H9/HTLV-IIIb isolate after digestion with 7 restriction endonucleases (SstI, PvuII, BglII, HindIII, EcoRI, CvnI, KpnI). Recombinant λ phage libraries from LW virus isolates from 9/4/85 (λOF001), 11/30/87 (λFD651), and 5/18/88 (λLW5A) were prepared and 10, 8, and 10 full-length HIV-1 clones, respectively, were analyzed. All 28 clones were identical to each other and to the BH10 clone of H9/HTLV-IIIb in 7 of 7 restriction enzyme patterns, except for 2 clones from the LW5A isolate that differed in single PvuII polymorphisms. The nucleotide and deduced amino acid sequences of the viral envelope gp120 immunodominant loop region (aa302-337) of 3 λOF001 clones, 3 λFD651 clones, and 6 λLW5A clones were determined and compared to a molecular proviral clone BH10 derived from the H9/HTLV-IIIb isolate, as follows:

```
λBH10    C T R P N N N T R K S I  R I  Q  R G P G R A F V T I  G K I  G  N M R Q A H C
λOF001   - - - - - - - - - - R -  - -  -  - - - - - - - - - -  - - -  -  - - - - - - -
λFD651   - - - - - - - - G - R -  - -  -  - - - - - T - - - -  - - -  -  - - - - - - -
λLW5A    - - K - - - - - G - R -  - -  -  - - - - - T - - - -  - - -  -  - - - - - - -
```

Clones from within each of the 3 LW isolates were identical to each other in the loop sequence but between isolates they showed cumulative nucleotide point mutations that resulted in the amino acid changes shown. Viral sequences were also amplified from uncultured LW PBL using the PCR technique and the loop regions sequenced. The envelope genes from λOF001, λFD651, λLW5A, and λBH10 clones were substituted into the HIV-1 proviral expression vector pHXB-2d and transfection-derived virus strains generated for analysis of antigenic and biologic properties. These studies demonstrate that cumulative changes develop in immunologically relevant regions of the HIV-1 envelope and will provide insight into the nature and significance of host-viral interactions mediated by this viral protein.

T.C.0.20 MOLECULAR CHARACTERIZATION AND COMPLETE NUCLEOTIDE SEQUENCE ANALYSIS OF AN ATTENUATED ISOLATE OF HIV-2

Kumar, Prasanna*; Hui, H.*; Kappes, J.C.*; Hoxie, J.A.**; Shaw, G.M.*; and Hahn, B.H.*
*University of Alabama at Birmingham, Birmingham, Alabama, USA; ** University of Pennsylvania, Philadelphia, Pennsylvania, USA.

HIV-1 and HIV-2 are two distinct classes of human immunodeficiency viruses known to cause AIDS in the US, Europe, and Africa. A particular isolate of HIV-2, termed HIV-2_{ST}, was recently obtained from a healthy prostitute from Senegal, West Africa, and was found to be less cytopathic *in vitro* when compared to prototype HIV-1, HIV-2_{ROD}, as well as SIV_{MAC} viruses (Kong, *et al.*, Science 240:1525, 1988). Biological comparisons revealed that HIV-2_{ST} infected cells did not form syncytia with CD4-bearing T-cell lines and that cell-free or cell-to-cell transmission of the virus was markedly delayed. In order to characterize HIV-2_{ST} molecularly, a recombinant λ-phage library was prepared from a highly-infected producer cell line. A full-length proviral clone designated λJSP4-27 was isolated, shown to be transfection competent and resemble the biological properties of the parental virus, and subsequently sequenced in its entirety. The data showed that the genomic organization of HIV-2_{ST} was very similar to that of HIV-2_{ROD} with the exception of an in-frame TAA stop codon in the vpr open reading frame. When compared to the prototype HIV-2_{ROD} sequence, an overall nucleotide sequence homology of 90% was observed. Amino acid homologies between different genes ranged from 75% for tat to 93% for gag. The envelope genes of HIV-2_{ST} and HIV-2_{ROD} differed considerably (18% amino acids), although their overall structure remained conserved. Interestingly, three amino acid changes were identified in the otherwise highly conserved envelope fusion domain of JSP4-27, suggesting they might be responsible for the nonfusogenic properties of this virus. To test this hypothesis, we PCR amplified, M13-cloned, and subsequently sequenced the fusion domains of two additional HIV-2_{ST} strains, one representing an early noncytopathic parental culture and the other representing a fusogenic variant of HIV-2_{ST} which had been generated by repeated cell-free passage. The data showed that 2 of 3 M13 clones derived from the fusogenic variant contained an additional, non-conservative change (Ala-->Arg) in the fusion domain, while the third clone as well as 3 of 3 M13 clones from the parental culture exhibited no changes as compared to the JSP4-27 proviral sequence. From these analyses we conclude that changes in the envelope fusion domain are, at least in part, responsible for the attenuated phenotype of the HIV-2_{ST} isolate. We also conclude that HIV-2_{ST} differs from HIV-2_{ROD} slightly more than do American HIV-1 viruses from each other, and that a functional vpr gene is not required for HIV-2 replication.

T.C.0.21 ANTIBODY-MEDIATED ENHANCEMENT OF HIV INFECTIVITY: MECHANISMS AND SIGNIFICANCE.

Homsy, Jacques*; Meyer, M.*; Tateno, M.*; Clarkson, S.** and Levy, J.A.*.
*Cancer Research Institute, University of California, School of Medicine, San Francisco, CA 94143, USA and ** Rosalind Russell Rheumatology Laboratory, San Francisco General Hospital, San Francisco, California, USA.

Objective: To investigate the host and viral range of antibody-dependent enhancement (ADE) of HIV infectivity and define the mechanisms involved in this phenomenon.
Methods: Enhancing experiments were conducted with different cell types derived from human peripheral blood. A variety of antibodies to block potential ADE receptors was used.
Results: Decomplemented anti-HIV antisera of both human and animal origin can enhance both HIV-1 and HIV-2 infectivity and cytopathicity in human macrophages and CD4+ lymphocytes obtained from the peripheral blood as well as fibroblastic cell lines. Such sera can also induce the tropism of certain HIV strains for macrophages.

Neither anti-CD4 monoclonal antibody nor soluble recombinant CD4 could inhibit HIV enhancement in CD4 lymphocytes, macrophages or fibroblasts. However, this phenomenon was inhibited by blocking the third Fc receptor (FcRIII) on macrophages. Other anti-FcRs antibodies had no effect. IgG aggregates but not anti-FcRIII antibodies could block HIV enhancement in CD4+ lymphocytes.
Conclusion: ADE of HIV infectivity is independent of the CD4 receptor and appears to require the presence of FcRIII on human macrophages. A different Fc receptor may be involved in enhancement of HIV in CD4+ lymphocytes and fibroblasts. These observations have important implications for the spread of HIV in vivo.

T.C.0.22 SEROLOGICAL AND MOLECULAR ANALYSIS OF THE IMMUNODOMINANT LOOP (IL) (296-331 a.a.) FROM NEUTRALIZATION RESISTANT VARIANTS DERIVED FROM HIV-1 IIIB INOCULATED CHIMPANZEES

Nara, Peter*; Dunlop, N.*; Waters, D.**; Smit, L.*** Goudsmit, J.***; Gallo, R.*
*National Cancer Institute, Frederick, Maryland, USA,**Program Resources, Inc., Frederick, Maryland, USA,***Academic Medical Center, Amsterdam, The Netherlands.

Objective: To determine the factors and epitopes of the IL amino acid (a.a.) 296-331, involved in the derivation of neutralization resistant variants (NRV) from the HIV-1 IIIB stock passaged through either chimpanzees or primary peripheral blood mononuclear cells (PBMC).
Methods: HIV-1 IIIB virus either passaged through human (H-) or chimp (C-) PBMC or sequentially re-isolated from experimentally HIV-1 IIIB infected chimpanzees were serologically typed, and the IL PCR amplified, cloned/or directly sequenced. Serologic analysis from the IIIB infected chimpanzees included ELISA based IL peptide analysis and serial neutralization analysis with three molecular clones of the IIIB stock, HX10, HXB2, and HXB3.
Results: A homogenous serotypic/genotypic IIIB-NRV resulted from single passage in C- and H-PBMC. Viruses from unvaccinated or gp120 immunized chimpanzees also demonstrated yet a different, homogenous genotypic/serotypic IIIB-NRV. NRV obtained later from these animals demonstrated additional IL a.a. substitutions. Neutralizing antibody (NA) produced to the inoculating strain is detected earliest. Sera obtained later now contains NA capable of recognizing the IIIB-NRV first established *in vivo*.
Conclusion: It appears that specific IIIB-NRV established *in vitro* or *in vivo* are due initially to selective forces other than NA. NA subsequently appears to induce/drive additional a.a. substitutions in the IL.

Origines des rétrovirus humains et modèles animaux
Origins of Human Retroviruses and Animal Models

T.C.O.23 THE ORIGINS OF HUMAN RETROVIRUSES

M. Essex, Harvard AIDS Institute:
Department of Cancer Biology,
Harvard School of Public Health, Boston,
Massachusetts, USA

When HIV-1 was first isolated and identified as the agent responsible for causing human AIDS, it was thought to be unique to the family of retroviruses. Since then two additional HIV-related viruses, SIV (Simian Immunodeficiency Virus) and HIV-2, have been identified and characterized; they both share the genetic complexity that was once believed to be unique to HIV-1. Based on nucleotide sequence homology, serologic cross-reactivity assays and genetic structural analyses, there seems to be a very close evolutionary relationship between SIV, which is naturally found in healthy African monkeys, and HIV-2, which infects humans in West Africa. HIV-1 is more distantly related to both.

Since SIV is highly prevalent in wild populations of common species of healthy African monkeys, it seems likely that this virus has little or no virulence in its natural host. However, when similar viruses infect the Asian macaque, which is an unnatural host for SIV, simian AIDS occurs with high frequency. Whether this variable pathogenicity is due to immunoevolutionary adaptation, to virus strain differences based on subtle genetic changes, or to both, is unclear. HIV-2 as well, appears to be less virulent than is either HIV-1 in humans, or SIV in Asian macaques; it is perhaps more virulent than SIV in African primates. Indeed, prospective studies with HIV-2 infected female prostitutes in West Africa suggest that the rate of disease development within this group is substantially lower than rates for similar cohorts of HIV-1 infected individuals in Central Africa.

T.C.O.24 TRANSGENIC CONSTRUCTS INVOLVING HIV-1 GENES

Martin, Malcolm A. Laboratory of Molecular Microbiology, National Institute of Allergy and Infectious Diseases, National Institute of Health, Bethesda, MD.

T.C.O.25 RELATIONSHIP AMONG PRIMATE RETROVIRUSES

Masanori HAYAMI
Institute for Virus Research, Kyoto University

Objective Several species of non-human primates are naturally infected with SIV genetically related to HIV. For understanding the origin and transmission of HIV/SIV, it is necessary to clarify genetical relationship of these viruses.
Methods Twenty isolates of SIV from African green monkey (SIV_{AGM}) originated in Ethiopia and Kenya, and two from mandrill (SIV_{MND}) in Gabon were obtained from naturally infected apparently healthy animals. Five of SIV_{AGM} and two of SIV_{MND} were molecularly cloned, and one of each was tatally sequenced.
Results The gene structures of SIV_{AGM} and SIV_{MND} are similar to other HIV/SIV, and functionally responsible elements known in each region of HIV-1 are also conserved in these viruses. However, SIV_{AGM} has *vpx* region but lacks *vpr* region while SIV_{MND} has *vpr* region but lacks *vpx* region . The amino acid sequence homologies of each region of these viruses HIV/SIV (HIV-1,HIV-2,SIV_{MAC} derived from rhesus monkey) and each other were almost equal, suggesting that they are equally distant each other except between HIV-2 and SIV_{MAC}. Although there was considerable genomic diversity among SIV_{AGM} isolates, no isolate was close to other HIV/SIV and no overlap with other HIV/SIV group viruses was observed.
Conclusion The species-specificity of SIV and unlikeliness of recent interspecies transmission among primates are suggested except for the case of HIV-2 and SIV_{MAC}.

T.C.O.26 PRIMATES FOR THE STUDY OF AIDS-RELATED DISORDERS

Eichberg, Jorg W., Southwest Foundation for Biomedical Research, San Antonio, Texas, USA

Objective. The establishment of various primate species as models for AIDS.
Methods. Baboons, rhesus monkeys, and chimpanzees were inoculated with HIV or SIV either with blood from AIDS patients, cell-free virus or in vitro infected autologous lymphocytes. In chimpanzees several cofactors such as type and dose of HIV inoculum, superinfection with other viruses, immunosuppression or immunostimulation were evaluated in the development of disease. In addition, approximately 30 chimpanzees were used in the evaluation of various vaccines such as peptides, recombinant proteins and hyperimmunoglobulin.
Results. Whereas baboons and rhesus monkeys could not be infected with HIV, chimpanzees were exquisitely sensitive to infection. However, virtually all cofactors, with the possible exception of the HIV dose, had no effect on the induction of HIV infection and the development of HIV-related disease. In contrast, chimpanzees were not susceptible to SIV infection. While baboons and rhesus monkeys were successfully infected with SIV only the latter showed evidence of immunosuppression with ensuing death. All HIV vaccines evaluated in 30 chimpanzees did either not confer protection or did not warrant challenge with live HIV.
Conclusion. Chimpanzees and rhesus monkeys are extremely sensitive to infection with HIV and SIV, respectively, and are therefore good models for HIV and SIV vaccine evaluation. Both animal species are useful studying parameters in disease development, however, only rhesus monkeys are good models for therapy evaluation.

Biologie moléculaire : les mécanismes de régulation de type *tat* des gènes viraux
Molecular Biology: TAT-Mediated Regulation of Viral Genes

T.C.0.27 THE TAR REGION OF HIV-1 BINDS AND ACTIVATES THE DOUBLE-STRANDED RNA DEPENDENT KINASE (DSI)

Roy, Sophie* Edery, I.*, Parkin, N.*, Petryshyn, R.**, Katze, M.***, and Sonenberg, N.*.
*McGill University, Montreal, Quebec, Canada, **State University of New York, Syracuse, New York, USA, ***Washington University, Seattle, Washington, USA.

Objective: To elucidate the mechanism by which the tat-responsive element (TAR) within the 5' non-coding region of HIV-1 mRNAs activates the double-stranded RNA dependent kinase (dsI), resulting in inhibition of protein synthesis, as observed in vitro in reticulocyte lysate.
Methods: An RNA mobility shift assay was devised to study nucleoprotein complex formation between dsI purified from reticulocyte lysate and small RNAs comprising the TAR region of HIV-1 (nucleotides +1 to +80).
Results: We show specific RNA-protein complex formation between dsI and TAR RNAs. Mutant TAR RNAs with reduced secondary structure loose their ability to bind dsI and are considerably less potent in activating the kinase. The introduction of compensatory mutations designed to restore the secondary structure of the TAR region restored the RNA's ability to complex with and activate dsI. An excess of the double-stranded RNAs polyI:C and reovirus dsRNA compete out complex formation and inhibit activation.
Conclusion: The double stranded nature of the TAR region present at the 5' end of all HIV-1 mRNAs renders it capable of activating dsI, a protein involved in the anti-viral response mediated by interferon. Activation of dsI correlates with the ability of the TAR RNA to bind to purified dsI. These studies may have important implications for the regulation of HIV-1 replication.

T.C.0.28 PROGRESSIVE GENETIC CHANGES IN HIV-1 TAT GENE COINCIDENT WITH DISEASE

Meyerhans, Andreas*, Cheynier, R.*, Saurin, W.*, Kwok, S.°, Sninsky, J.°, Alberts, J.**, Asjo, B.** and Wain-Hobson, S.*
*Institut Pasteur, Paris, France ; °Cetus Corporation, Emeryville, USA ; **Karolinska Institute, Stockholm, Suède.

Objective : Analysis of the HIV-1 proviral population of four virus isolates taken from the same individual as he progressed towards AIDS (PGL - ARC - AIDS).
Methods : Tat gene sequences were amplified by PCR and cloned into an expression vector. Twenty plasmid clones of each isolate were sequenced.
Results and conclusions : 1) Comparing viral populations after short term culture, significant changes in the dominant viral species were observed during disease progression. This effect is less prominent with tat variants obtained directly from lymphocytes. 2) In vitro cultivation distorts the virus population present in blood lymphocytes, whereas long term cultivation does not constitute a further selective pressure. 3) On the protein level, single and multiple amino acid changes as well as defective genomes were observed. Functional studies complementing the structural analysis underway will allow us to interpret better these data.

T.C.0.29 BINDING OF THE HIV-1 TAT PROTEIN TO TAR SEQUENCES IN VITRO.

Dingwall, C.; Ernberg, I.; Heaphy, S.; Skinner, M. A.; Gait, M. J. & Karn, J.
MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 2QH, U.K.

Objective. To investigate the binding *in vitro* of HIV tat protein and cellular factors to TAR sequences.

Methods. A synthetic *tat* gene has been expressed both in an *E. coli* expression system and in a number of eukaryotic cell lines. The binding of expressed tat protein to nucleic acid representing the TAR sequence has been investigated *in vitro* using gel retardation assays.

Results. The tat protein produced from both the *E. coli* and from the eukaryotic expression systems has been shown to be biologically active. The binding of tat, synthesised *in E. coli*, to TAR nucleic acid has been examined both in the presence and absence of host cellular proteins. Binding of tat expressed in eukaryotic cells gives a different pattern, suggesting that host proteins interact with the tat/TAR complex. The specificity of binding has been examined using a number of different nucleic acids, including mutant TAR sequences.

Conclusion. Direct interactions between tat protein and TAR sequences are involved in *trans*-activation.

T.C.0.30 SIV_{mac} (BK28) HAS THE CAPACITY TO ENCODE ISOFORMS OF THE TAT AND REV PROTEINS THROUGH ALTERNATE mRNA SPLICING

Viglianti, Gregory A. and Mullins, J.I.
Harvard School of Public Health, Boston, Massachusetts, USA

Objective. We previously demonstrated that, in contrast to HIV-1, coding exon 2 of SIVmac (BK28) tat is required for significant tat activity and that disruption of the presumed splice acceptor at the start of this exon activates a downstream splice acceptor site and results in the formation of a functional tat protein. We now seek to characterize the structure and functional coding capacity of mRNA molecules which encode the SIV_{mac} tat and rev proteins.
Methods. Polymerase chain reaction was used to specifically amplify cDNAs corresponding to either tat or rev mRNAs from SIV_{mac} (BK28) infected HuT78 cells and the different spliced forms were characterized by oligonucleotide probe hybridization and DNA sequencing.
Results. We found that tat and rev mRNAs use different splice acceptor sites at the beginning of their respective first coding exons. Three different splice acceptor sites are used at the beginning of tat coding exon 2. The different mRNAs which utilize these sites have the capacity to encode proteins which differ by single amino acid substitutions and the deletion of either 1 or 6 amino acids. The two 5' most splice acceptor sites, which incidently flank the stop codon in the env reading frame (see abstract by Edmonson et al), were used at frequencies of 54% and 45%, while the 3' most site was used at a frequency of 2%. Similar splicing events which join rev coding exons 1 and 2 were also identified. They were used at frequencies of 61%, 37% and 1.7%, respectively. Finally, rev mRNAs fall into 2 classes with respect to their 5' structure. These classes are approximately equivalent in frequency and differ by the presence or absence of a 144 nucleotide intron located within the R region of the LTR. The biological activity of clones of each of the tat and rev cDNAs are currently under investigation.
Conclusion. SIVmac uses alternative splicing to generate mRNAs with the capacity to encode isoforms of the tat and rev proteins.

T.C.0.31 BINDING OF HIV-1 TAT TO THE 5' REGION OF mRNA

Rappaport Jay E., Josephs S., Klotman M., Kang C.Y., Daefler S., Rusche J., and Wong-Staal F. Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Md.U.S.A.

Objective: HIV-1 gene expression is positively regulated by the viral transregulatory protein, tat. Evidence suggests that the structure of the RNA stem loop within the TAR region is critical for transactivation therefore we proposed that the tat protein binds directly to this RNA structure.

Methods: Recombinant tat protein produced in both E. coli and baculovirus expression systems were tested for their ability to bind directly to gel-purified ^{32}P-labeled transcripts from the initial 5' 80 nucleotides of the HIV-1 mRNA that were synthesized from constructs using the bacteriophage T7 polymerase. RNA gel mobility shift assays were performed using the wild type as well as a mutant transcript (ΔS) generated by a four base pair deletion (+35-+38) at the SST1 site, known to lack transactivation potential.

Results: Introduction of the recombinant tat proteins by the "scrape-loading" procedure into HeLa cells stably integrated with the HIV-1 LTR linked to the bacterial chloramphenicol acetyl transferase gene confirmed the activity of the proteins. Wild-type TAR transcripts formed a stable complex with the recombinant tat proteins resulting in retarded gel migration. The deleted transcript (ΔS) did not form a stable complex.

Conclusion: The data suggest that tat protein of HIV-1 specifically and stably binds to TAR RNA which may be a required step in vivo in the transactivation pathway.

T.C.0.32 CD8+ LYMPHOCYTES CAN CONTROL ACUTE HIV INFECTION OF CD4+ T CELLS

Walker, Christopher M., Thomson-Honnebier, G.; Hsieh, F. and Levy, J.A.
Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To determine if peripheral blood CD8+ T cells from HIV-infected subjects can suppress the growth of HIV in acutely infected CD4+ T cells.
Methods: Peripheral blood mononuclear cells from HIV-infected and uninfected subjects were stimulated with PHA for three days, and T lymphocyte subsets expressing the CD4+ and CD8+ surface antigens were enriched by immunoaffinity selection. CD4+ cells were infected with an HIV isolate, and then cultured with the CD8+ T lymphocytes. Culture supernatants were assayed every three days for reverse transcriptase activity.
Results: CD8+ T cells from HIV-1 seropositive subjects, but not seronegative controls, were able to prevent replication of HIV in acutely infected CD4+ T cells. Suppression of virus growth required the continuous presence of CD8+ T cells, and was not HLA-restricted. Monoclonal antibodies to antigens on mature T cells (i.e. CD3 and CD8 positive), but not cells that can mediate antibody-dependent cellular cytotoxicity or natural killing (i.e. CD16 positive) blocked suppression when added to the culture. The response was broadly cross-reactive; replication of an HIV-2 isolate could also be suppressed by CD8+ cells from HIV-1 infected subjects.
Conclusion: Cytotoxic suppressor T lymphocytes can prevent the growth of HIV after acute infection and are present in the peripheral blood of HIV-infected individuals. The mechanism of action of these CD8+ T cells remains to be determined.

Virologie (partie 2)
Virology (Part 2)

T.C.0.33 IDENTIFICATION OF SITES WITHIN GP41 WHICH SERVE AS TARGETS FOR ADCC USING HUMAN MONOCLONAL ANTIBODIES.

Tyler, Douglas*; Zolla-Pazner, S.**,***; Gorny, M.**; Stanley, D.*; Bolognesi, D.* and Weinhold, K*., *Duke University Medical Center, Durham, NC, USA. **New York University Medical Center and *** New York VA Medical Center, NY, NY, USA.

Objective: To utilize human anti-HIV-1 monoclonal antibodies (mAb) to define target epitopes for antibody-dependent cellular cytotoxicity (ADCC).
Methods: PBMC from HIV-1 infected individuals were EBV transformed, screened for mAb production, cloned and maintained in long term culture. Six cell lines made mAb to gp41 and five made mAb to p24. These mAb were tested in 6 hr ^{51}Cr release ADCC assays using virally infected and gp120 adsorbed CEM.NKR targets.
Results: None of the anti-p24 mAb mediated ADCC. However, five of the 6 mAb directed at regions within gp 41 mediated significant lysis of IIIB, RF and MN infected targets, at dilutions in the range of 1-5x10^{-8} M. No lysis of gp120 adsorbed targets was seen. The specific lysis of the three most effective mAb at two dilutions is shown in the table. Interestingly, the isotype of all ADCC directing anti-gp41 mAb was IgG2, not IgG1(the predominant isotype of ADCC mediating antibodies in patient sera).

	IIIB		RF		MN		GP120	
mAb (isotype)	1:4	1:100	1:4	1:100	1:4	1:100	1:4	1:100
120-16 (IgG2)	29.2	16.0	22.7	11.5	7.0	5.0	1.2	2.5
126-50 (IgG2)	22.5	10.1	19.4	6.7	6.7	4.4	2.0	1.9
98-6 (IgG2)	20.8	6.7	20.0	4.6	4.5	4.0	2.3	1.1

Conclusion: These results for the first time assign a protective functional activity to antibodies directed against the immunodominant region of gp41. The purity, potency and broad specificity of these human mAb makes them ideal for passive immunotherapy. Current work on the identification of the specific epitopes to which these mAb are directed will facilitate the design and development of a future vaccine.

T.C.0.35 PUTATIVE INTERACTION SITE BETWEEN HIV gp120 AND gp41 : ANTIVIRAL ACTION OF SYNTHETIC PEPTIDES.

McPhee, Dale*; Pavuk, N.*; Cumming, S.*; Stapleton, D.**; Doherty, R.* and Kemp, B.**
*NHMRC Special Unit for AIDS Virology, Fairfield Hospital, and
**St. Vincent's Institute, Melbourne, Victoria, Australia.

Objective: To determine the antiviral action of synthetic peptide analogs corresponding to a putative interaction site between envelope glycoproteins gp120 and gp41, of HIV.
Methods: Purified synthetic peptides of 8 to 25 residues were tested (at 10-100uM) for their ability to inhibit HIV replication 'in vitro' at moi of 0.0005–0.02 pfu/cell.
Results: We have identified a region in gp120 (99-119) and a complementary sequence in gp41 (571-591) with four matched charge residues conserved for all HIV isolates which has a propensity to form amphipathic helices with charged residue contacts and complementary hydrophobic residues. Synthetic peptide analogs partially spanning either region inhibited virus replication as measured by reverse transcriptase activity and delayed syncytial formation.
Conclusion: Our results illustrate that it is possible to reduce HIV infectivity with synthetic peptides that mimic structures involved in the contact region between gp120 and gp41.

T.C.0.37 DEFINITION OF EPITOPES ALONG A IMMUNO-DOMINANT REGION OF THE HIV-1 GP41 AND THE EFFECT OF CONSERVATIVE AND NON-CONSERVATIVE AMINO ACID SUBSTITUTIONS CORRESPONDING TO VARIOUS HIV-1 ISOLATES

Horal, Peter ; Jeansson, S. ; Svennerholm, B. ; Rymo, L. ; Vahlne, A.
Departments of Clinical Virology and Medical Biochemistry, University of Göteborg, Sweden.

Objective. To delineate precise epitope locations for continuous epitopes along a region of the HIV-1 gp41, previously shown to be immuno-dominant, and to study the reactivity of sera from different parts of the world to synthetic peptides with amino acid substitutions according to known isolates.
Methods. Eighteen hexapeptides overlapping by five amino acids (aa) spanning a 23 amino acid segment, previously shown strongly immuno-reactive, of the env gene corresponding to aa 596-618 were synthesized on solid-phase pins (Geysen technique). These peptide-pins were then assayed in a standard indirect ELISA against three different HIV-1 positive sera.
Furthermore nine variants containing conservative and non-conservative aa substitutions of the 23-mer peptide were synthesized. Each variant, representing sequenced isolates of HIV-1, were assayed against a large serum panel of HIV-1 positive sera originating from different parts of the world.
Results. Five different epitopes confined within the 23-mer peptide could be distinguished. Different sera tested against the panel of nine variant peptides exhibited different patterns as to their individual reactivity to the various peptides. In particular the reactivity pattern of some East African sera will be discussed. Non-conservative as well as conservative single aa substitutions in an epitope drastically can alter its reactivity with individual sera.
Conclusion. Within a small sized (23 aa) immuno-dominant peptide as many as five different epitopes can be distinguished but individual serum samples may not show reactivity to all of them. A conservative single aa substitution may alter the immune reactivity of an epitope.
Small synthetic peptides representing different HIV-1 isolates may be useful in epidemiologic studies of the HIV-1 pandemic.

T.C.0.34 FUNCTIONAL DOMAINS ON THE HIV-1 ENVELOPE PROTEIN

Earl, Patricia L. and Moss, B.
Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, Bethesda MD 20892, USA

Objective. To examine the functional domains on the HIV-1 envelope (env) glycoprotein.
Methods. Recombinant vaccinia viruses containing intact or mutated forms of the HIV-1 env gene were constructed.
Results. Cells, infected with a recombinant virus that contains the entire env gene, synthesized glycosylated gp160 which was cleaved to gp120 and gp41 and inserted into the plasma membrane leading to CD4 binding and syncytium formation. When the DNA encoding the proteolytic cleavage site was deleted, gp160 was no longer cleaved, was inserted into the plasma membrane, but no syncytia were formed. Isolated gp160 was still able to bind soluble CD4.

A family of recombinant vaccinia viruses that express N-terminal overlapping env proteins of 204, 287, 393, 506 (gp120), 635, 747, and 851 (gp160) amino acids (aa) were constructed. Only the 747 aa and the full-length proteins mediated syncytium formation. The remaining proteins were all present in intracellular and secreted forms which differed in extent of glycosylation. Curiously, the 393 aa protein also was anchored in the plasma membrane but neither it nor smaller proteins bound to CD4.
Conclusions. (1) Uncleaved gp160 can insert into the plasma membrane and bind to CD4; (2) cleavage of gp160 is required for fusion to CD4-bearing cells; (3) the carboxy terminal 104 aa are not required for anchorage or fusion; (4) the transmembrane domain is between aa 635 and 747; (5) the CD4 binding domain is between aa 393 and 506; (6) a cryptic membrane anchor sequence is between aa 287 and 393.

T.C.0.36 CHARACTERIZATION OF THE HIV-2 ENVELOPE GLYCOPROTEINS : THE TRANSMEMBRANE GLYCOPROTEIN IS A HOMODIMER

Rey, Marie-Anne ; Laurent, A.G.; McClure,J.*; Krust,B.; Montagnier, L. and Hovanessian A. G.
Institut Pasteur, Paris 15, France ; *Genetic Systems, Seattle, Washington,U.S.A.

Objective : Identification of HIV-2 envelope external and transmembrane glycoprotein (EGP and TMP) by polyclonal and monoclonal antibodies.
Results : A 80-Mr glycoprotein (gp80) is produced in HIV-2 infected cells along with three other glycoproteins that we have recently reported : the external glycoprotein (gp125), the envelope glycoprotein precursor (gp140) and the transient dimeric form of gp140 (gp300). The gp125 and gp80 are detectable after the synthesis of gp140 and the formation of gp300. Among these four glycoproteins, only gp80 and gp125 are associated with HIV-2 virions. As the other glycoproteins, gp80 can be recognized by all HIV-2 positive sera. A murine polyclonal antibody raised against the purified gp300 recognizes all four glycoproteins. On the other hand, a monoclonal antibody raised against a synthetic polypeptide deduced from the sequence of TMP of HIV-2 recognizes gp140, gp300 and gp80; thus indicating that gp80 should be related to TMP of the envelope. Heating (95°C, 5 min) of cellular or viral extracts in 1% SDS results in the dissociation of gp80 into the monomer gp36. These results suggest that during the processing of the HIV-2 envelope glycoprotein gp140, the dimer is produced which when cleaved by the cellular protease gives the EGP gp125 and TMP dimer gp80.
Conclusion : Dimerization of envelope glycoprotein precursor and the TMP is a specific property of HIV-2 and SIV gene expression. Dimerization of the precursor might be required for its processing to give the mature envelope products whereas the TMP dimer might be essential for optimal structure of the virion.

T.C.0.38 gp160 IS ENDOPROTEOLYTICALLY CLEAVED IN A PREFUCOSYLTRANSFERASE CONTAINING COMPARTMENT OF THE GOLGI COMPLEX.

Barry S. Stein*, K.S. Steimer**, and E.G. Engleman*. *Stanford University School of Medicine, Palo Alto, CA 94304, USA, **Chiron Corporation, Emeryville, CA 94608, USA.

Objective: To identify the intracellular site of endoproteolytic cleavage of the HIV-1 gp160 envelope precursor.
Methods: HIV-1 envelope glycoprotein determinants were immunoprecipitated from an acutely infected CD4+ T cell line (VB) radiolabeled with [^{35}S]cysteine and [^{35}S]methionine or [^{3}H]fucose and subjected to one- and two-dimensional SDS-PAGE.
Results: gp160 contains 70 kD of endo H sensitive N-asparagine linked high mannose carbohydrate side chains, is devoid of fucose and is neuraminidase resistant (pI - 7.0 to 7.5). gp160 is not transported to the cell surface, but binds to CD4. gp120 has approximately 20 kD of endo H sensitive and 55 kD of N-glycanase sensitive N-asparagine linked oligosaccharides signifying both high mannose and complex side chains. gp120 is rich in fucose and sialic acid, with a broad pI of 5.0 to 7.5 that shifts above 7.0 upon neuraminidase treatment. N-glycanase shifts the pI of gp120 toward the acidic range (5.5 to 6.5) suggesting the presence of abundant sialylated O-linked sugars. Pulse chase studies with 1-deoxymannojirimycin indicate that gp160 has a transit time of approximately 2 hours to the site of action of Golgi α-mannosidase I and that its endoproteolytic cleavage occurs before processing by this mannose trimming enzyme. gp160 cleavage is achieved by a non-acid dependent protease.
Conclusions: gp160 is endoproteolytically cleaved in a prefucosyltransferase compartment of the Golgi complex, likely before processing by Golgi α-mannosidase I, which is consistent with localization to the RER-*cis* Golgi interface.

T.C.0.39

PREVENTION OF SIMIAN AIDS BY PASSIVE PROTECTION

Malcolm R. MacKenzie C. Zaiss, P. Marx, D. Maul, and N. Lerche. University of California, Davis and the California Regional Primate Center, Davis, California, U.S.A.

The problem of prevention of inadvertent infection of HIV in health care workers is of serious concern. We are exploring the use of high-titered neutralizing antibody for passive protection in primate models of retroviral infection. The SRV-1 induced immunodeficiency disease of Rhesus Macaques was chosen as our group demonstrated the successful use of active immunization to control the diease. Twelve animals were innoculated with 1.2X10^6 infectious units of SRV-1. Four animals were given control IgG. Four were given high titer neutralizing IgG in a dose of 20 mg/kg 24 hours before challenge, four 24 hours after challenge. Serial blood samples were analyzed for the presence of neutralizing antibody, antiSRV antibody (by ELISA), and for virus. The animals were observed clinically for SAIDS. Results: The 4 control animals show a pattern of incrasing titer of virus and symptoms of SAIDS. One animal has died. All animals given passive protection demonstrated neutralizing antibody on day 2 through day 14. Five of 8 animals cleared all virus by day 14 and are currently alive and without signs of overt SAIDS. Two animals in this group died and one has signs of SAIDS. Eleven of the 12 animals developed titers of antiSRV antibody indicating the induction of a primary immune response. Passively administered IgG is able to reduce the virus load in 5 of 8 animals (62%) and avert disease.

T.C.0.41

CHARACTERISTICS OF SIV_{AGM} ISOLATED FROM WILD CAUGHT ANIMALS IN CENTRAL AFRICAN REPUBLIC (CAR)

Georges-Courbot,M.C.* ; Lang,M.C.** ; Sonigo,P.** ; Jennings,M.*** ; Georges,A.J.* ; Barré-Sinoussi,Françoise** et al.
*Institut Pasteur, Bangui (CAR), ** Institut Pasteur, Paris (France), ***University of California, Davis (USA)

Objective. To determine specific features of SIV_{AGM} isolates from CAR by comparison with prototype HIV/SIV viruses.
Methods. Virus isolation from blood samples of monkeys selected as seropositive by HIV_2 blot. Infectivity and cytopathogenicity of isolated strains for human and monkey cells. Immunologic relatedness with HIV/SIV prototypes. Experimental inoculation into African monkeys.
Results. Among 337 wild caught monkeys including 9 species from CAR, 3 out of 26 healthy AGM were found seropositive by HIV_2 blot. Viruses recovered from their PBL replicate easily in AGM lymphocytes but are poorly infectious and cytopathic for human cells. EM study on one isolate shows the typical HIV/SIV morphology. Immunological cross-reactivities with both HIV_2 and HIV_1 internal proteins as well as with HIV_2 env proteins were observed. Antigenic homology with the immunodominant epitope of HIV_2 Gp36 was found by a peptide assay. Finally, experimental transmission into Patas monkeys from CAR resulted in seroconversion within 5 weeks.
Conclusions. Differences in biological features of SIV isolates from wild caught monkeys in different regions of Africa probably reflect viral genetic diversity. Comparisons of SIV strains at a molecular level are in progress to evaluate the relationship between pathogenicity and peculiar genetic properties.

T.C.0.43

SIV FROM SOOTY MANGABEY MONKEYS: AN AFRICAN PRIMATE LENTIVIRUS CLOSELY RELATED TO HIV-2.

Hirsch, V.M.*, Murphey-Corb, M.** and Johnson, P.R.*, *Georgetown University, Rockville, MD, **Delta Regional Primate Research Center, Covington, LA. USA

Objective. The human immunodeficiency viruses may have evolved from ancestors that originated within a reservoir of African primate lentiviruses (SIVs). None of the SIV strains characterised to date share a close relationship with HIV-1. However, HIV-2 is closely related to SIV isolated from captive macaques (SIVmac). Since macaques are not infected in the wild, captive macaques may have been infected by cross-species transmission from an SIV- infected African primate. Sooty mangabeys, a primate species indigenous to West Africa, are infected with SIV (SIVsmm) both in captivity and the wild (pers. comm. , P. Fultz). Thus, we undertook molecular analysis of SIVsmm to establish its relationship to other primate lentiviruses.
Methods/Results. SIVsmm was molecularly cloned and the nucleotide sequence of an infectious clone (smH-4) determined. SIVsmm shares the same genetic organization as SIVmac and HIV-2. Comparison of the predicted protein products of SIVsmm, SIVmac, and HIV-2 revealed significant sequence identity among these viruses (as shown in the table).

SIVsmm vs:	gag	pol	vif	vpx	vpr	tat	rev	env	nef
SIVmac	90	92	84	93	90	72	70	82	77
HIV-2	83	84	69	80	78	65	62	72	64

Evolutionary tree analysis (nucleotide and protein) was in agreement with predictions based on average identity comparisons.
Conclusion. These data suggest that: i) SIVsmm may have been the source of SIVmac; and, ii) SIVsmm or its immediate ancestor may have entered the human population in West Africa and evolved as HIV-2.

T.C.0.40

GENETIC CHARACTERIZATION OF AN ACUTELY LETHAL VARIANT OF SIV/SMN.

Françoise Lauré*; Courgnaud, V.*; Fultz, P.N.**; Montagnier, L.***; Bréchot, C.* *** and Sonigo, P.***.
*INSERM U.75, CHU Necker, Paris, **Emory University and Yerkes Primate Center, Atlanta, USA, ***INSERM U.163, Institut Pasteur, Paris, France.

Objective. To analyse the genome of an SIV variant with altered phenotypic properties and pathogenicity for macaques and mangabey monkeys, called PBj14.
Methods. 1) PCR with primers corresponding to conserved SIV sequences on DNA from lymphocytes infected with the lethal variant PBj14 or the original isolate SIV/SMN. 2) Cloning and sequencing.
Results. PBj14 and SIV/SMN genomes are closely related to SIVmac genome. However, many mutations and insertion-deletions are observed.
Conclusion. These genetic differences may account for the particular phenotype of PBJ14. Sequence analysis are ongoing.

T.C.0.42

PROPHYLACTIC EFFECTS OF AZT FOLLOWING EXPOSURE OF MACAQUES TO AN ACUTELY LETHAL VARIANT OF SIV (SIV/SMM/PBJ-14)

McClure, Harold M., Anderson, D.C., Fultz, P., Ansari, A., Brodie, A. and Lehrman, S.
Yerkes Regional Primate Research Center and Department of Pathology, Emory University, Atlanta, GA and *Department of Virology, Burroughs Wellcome Company, Research Triangle Park, NC, U.S.A.

Objective. To determine the prophylactic effects of AZT when administered shortly after exposure to an acutely lethal variant of SIV.
Methods. Four groups of 3 pig-tailed macaques were given 10 $TCID_{50}$ of SIV/SMM/PBj-14. AZT at 100mg/kg/day, divided into 3 doses, was given S/Q for 14 days. Treatment was initiated at 1 (group 1), 24 (group 2) or 72 (group 3) hours after virus exposure; group 4 was untreated.
Results. All animals except one in group 1 were virus positive at 10 days post-inoculation (P.I.). Three animals in groups 1 and 2 remained clinically normal; all other animals developed disease within 10-17 days of virus exposure. One death occurred in group 1, and 2 deaths occurred in each of the other groups. Survivors in groups 3 and 4 are showing clinical disease and immunosuppression, whereas survivors in groups 1 and 2 are clinically normal with normal immunologic parameters (8 mo P.I.). One animal in group 1 has no evidence of SIV infection. Survivors in groups 3 and 4 have 30-fold higher Ab titers than survivors in groups 1 and 2, suggesting that the former had more antigenic stimulation due to increased virus replication.
Conclusion. These data indicate that some protection is provided by AZT when treatment is initiated within 24 hours of exposure to an acutely lethal variant of SIV. (Supported by NIH grant RR00165 and Burroughs Wellcome).

T.C.0.44

HIV-1 INFECTION OF HUMAN PBL-RECONSTITUTED SCID MICE

Donald E. Mosier*; R.J. Gulizia*; S.A. Spector**; D.H. Spector**; S.M. Baird** and D.B. Wilson*.
*Medical Biology Institute, La Jolla, CA 92037, **University of California, San Diego, San Diego, CA, U.S.A.

OBJECTIVE - To determine if SCID mice reconstituted with human lymphoid cells can be infected with HIV and if the infection results in pathology.
METHODS - Normal adult peripheral blood leucocytes (PBL) were injected into immunodeficient C.B-17 SCID mice, which results in survival and expansion of human T and B lymphocytes and the reconstitution of human antibody responses. A series of SCID mice reconstituted with PBL from an Epstein-Barr virus seronegative donor have been injected with the LAV-1 strain of HIV-1 at 2-8 weeks post-reconstitution.
RESULTS - Virus has been recovered from the lymphoid tissue and peripheral blood of these animals at 2, 4, and 6 weeks post-infection by co-cultivation with fresh T cell blasts, and viral replication has been confirmed by *in situ* hybridization and detection of viral sequences using the polymerase chain reaction.
Mice with high viral titers have shown evidence of human T cell depletion. These results support the use of the human lymphoid cell-reconstituted SCID mouse as a relevent AIDS model.

Biologie moléculaire : les gènes régulateurs et leurs produits
Molecular Biology: Regulatory Genes and Their Products

T.C.0.45

LOCALIZATION OF THE VPR GENE PRODUCT IN SIVmac INFECTED CELLS

Jänel, G.; Lang, Sabine; Weeger, M; and Fleckenstein, B.
Institut f. Klinische und Molekulare Virologie, Universität Erlangen-Nürnberg, 8520 Erlangen, FRG

The high degree of sequence conservation of the vpr protein between HIV-1, HIV-2, and SIVmac suggests a significant function for vpr in these viruses. There is, however, no detectable vpr gene in the genome of SIVagm. We expressed the vpr open reading frame of SIVmac as a ß-gal fusion protein in E. coli. This protein is immunogenic and is recognized by sera of SIVmac infected rhesus monkeys as well as by sera of HIV-1 seropositive people. The recombinant ß-gal-vpr fusion protein was purified and used to raise heterologous antisera in rabbits. Data from cell fractionation and immunofluorescence where we show the localization of the vpr gene product in SIVmac infected cells will be presented. Analysis of cellular extracts taken at different time points post infection provide evidence for an important regulatory function of the vpr protein in the course of viral infection.

T.C.0.46

VIRAL PROTEIN R (VPR) OF HIV-1 AND HIV-2 IS DISPENSABLE FOR REPLICATION AND CYTOPATHICITY

Douglas Dedera, W Hu, M Vander Heyden, and L Ratner. Departments of Medicine and Microbiology & Immunology, Washington University, St. Louis, Mo., USA

Objective: The vpr gene is found in HIV-1, HIV-2, and SIV-MAC and antibodies to VPR are found in HIV-1 infected individuals. The goal of this study was to define the activity of VPR.
Methods: A functional proviral clone of HIV-1, X, was used to construct proviral clones with frameshift or site directed mutations which truncate the VPR protein from 78 to 40, 31, 22, or 2 amino acids. The functional proviral clone of HIV-2, SE, was used to construct a proviral clone with a site directed mutation which truncates the VPR protein from 105 amino acids to 6 amino acids. Each clone was transfected into COS-1 cells, and then cocultivated with H9 or CEM lymphoid cells to produce virus preparations.
Results: Virus produced from each vpr mutant provirus was compared to that produced by the parental clone, X or SE. No significant differences were noted in their infectivity, replication properties, or cytopathicity for different lymphoid cell lines (Jurkat, H9, Molt 3, CEM, Sup T1), monocytoid cell line (U937), or peripheral blood lymphocytes. Southern blot hybridization confirmed the presence of the mutation in DNA from the infected cells, and demonstrated a similar level of DNA sequences in cells infected with the parental virus and those infected with the vpr mutants.
Conclusions: VPR is dispensable for virus replication and cytopathicity in tissue culture. Experiments are currently in progress to define the role of vpr in animal model systems.

T.C.0.47

FUNCTIONAL CHARACTERIZATION OF THE HIV-1 vpu GENE PRODUCT: NOT JUST ANOTHER PROTEIN

Strebel, Klaus; Klimkait, T.; Maldarelli, F. and Martin, M.A.
Laboratory of Molecular Microbiology, NIAID, NIH; Bethesda, MD 20892, USA.

Objective. To describe the structure of the HIV-1 vpu gene product and its function in the viral replication cycle.
Methods. We used a variety of molecular biological, biochemical and immunological techniques to analyse post-translational modification of vpu, to determine its localization inside the cells, and to analyze the effects of vpu on synthesis, processing or turnover of other viral proteins.
Results. The HIV-1 vpu protein is a non-glycosylated, membrane-associated, phosphoprotein which is expressed in large amounts in HIV-infected cells. It does not appear to be virion-associated. The absence of a functional vpu results in the reduction of HIV-1 particles released from infected cells and in the accumulation of viral proteins intracellularly.
Conclusion. Our data suggest that vpu is a matrix protein that is involved in regulating particle-release from infected cells.

T.C.0.49

ANALYSIS OF A POTENTIAL HIV-1 CODING SEQUENCE.

Cohen, Eric A.; Jalinoos, Y.; Terwilliger, E.; Lu, Y.; Haseltine, W. Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA U.S.A.

Objective: To determine if an open reading frame of HIV-1 is a coding sequence.

Methods & Results: The region encoding the possible open reading frame was cloned into an in vitro transcription vector. The ability of the potential open reading frame to encode a protein was examined by programming an in vitro reticulocyte lysate with RNA synthesized in vitro by SP6 RNA polymerase. Analysis of the product of the open reading frame produced in the in vitro lysate using rabbit sera directed against oligopeptides derived from the amino acid sequence of the coding sequence indicates that the open reading frame is expressed in rabbit reticulocyte lysates as a fusion of two reading frames by ribosomal frameshifting.

Conclusion: Our results indicate that in addition to gag, pol, env, vif, vpr, tat, rev, vpu and nef, HIV-1 contains another potential coding sequence that is expressed as a fusion protein in cell-free translation extracts.

IDENTIFICATION OF NOVEL HIV-1 mRNAs BY S1 NUCLEASE ANALYSIS AND PCR AMPLIFICATION

Felber, Barbara K.*, Schwartz, S.**, Drysdale, C. M.*, Fenyo, E.M.**, & Pavlakis, G. N.*
*BRI-Basic Research Program, NCI-FCRF, Frederick, MD 21701 USA
**Karolinska Institute, Stockholm, Sweden

Objective. To study the expression of several different HIV-1 isolates and to correlate the expression with the cytopathic and pathogenic potential of these isolates.
Methods. Polymerase chain reaction (PCR), S1 nuclease and Northern hybridization analyses.
Results. We have analyzed the mRNA species produced by HIV-1 after infection of human lymphocytes and after transfections of proviral DNA clones into human cells. New mRNA species were identified by S1 nuclease analysis. Viral mRNA was also converted to cDNA and amplified by PCR. mRNAs of lengths up to 2 kilobases were successfully amplified by this procedure, allowing the study of all the multiply spliced mRNA species in their entirety. It was found that HIV-1 produces more mRNA species than previously described. The complete characterization and regulation of these mRNAs is currently under investigation. A collection of HIV-1 isolates with variable growth and cytopathic in vitro properties were studied. DNA fragments of these isolates were also amplified successfully by PCR using appropriate primers. Fragments of lengths up to 4 kilobases have been amplified. This method allows the fast cloning of functional domains from different virus isolates and the introduction into appropriate expression vectors for further study.
Conclusion. PCR is a fast and reliable method for the amplification and study of HIV-1 DNA and RNA. It is anticipated that this methodology will allow the isolation and characterization of all viral mRNAs and will provide valuable information about the mechanisms of virus pathogenicity.

Feline immunodeficiency virus (FIV) is a T-lymphotropic, cytopathic lentivirus associated with a fatal immunodeficiency syndrome in domestic cats. Disease symptoms include lymphadenopathy, hematologic abnormalities, wasting, diarrhea, and susceptibility to opportunistic pathogens. We have molecularly cloned proviruses from FIV-infected tissue culture cells. One clone was shown to give rise to infectious virus after DNA-transfection of permissive cells. The complete nucleotide sequence of this clone has been determined. The proviral clone has a total length of 9,472 base pairs (bp). Long terminal repeats (LTRs) are 355 bp and contain cis-acting regulatory elements including the TATA box for initiation of transcription and a candidate enhancer element that closely matches the NF-kappa B binding site. The initiation site in the LTR for viral transcripts has been identified by primer-extension. Similar to other lentiviruses, FIV utilizes a tRNA-lys primer binding site. Three long open reading frames (orfs) encoding the gag, pol, and env genes are evident. FIV contains an orf that overlaps the 3' end of pol; this orf corresponds to the viral infectivity factor (vif) of primate lentiviruses. Several short orfs are present in the intergenic region between pol and env and within env; these orfs may serve as exons for viral transactivator functions. Orfs are also found in the region after the env gene extending into the rightward LTR. Alignment of the predicted amino acid sequences of the FIV proteins with those of other lentiviruses indicates that FIV is unique and did not arise recently from other known lentiviruses. Virologic, clinical, and genetic features of FIV suggest that this animal lentivirus may be a useful model for HIV infection and AIDS.

W.C.O.3 VIRAL MUTOGENESIS

W.C.O.4 THE HIV-QUASISPECIES : A NECESSARY DESCRIPTION

Simon Wain-Hobson, Laboratoire de Biologie et Immunologie Moléculaires des Rétrovirus, Institut Pasteur Paris, France

The HIV genome is extremely plastic. Genetic variation is greatest in the region corresponding to the surface glycoprotein, gp120. It appears so far that every isolate studied is quite distinct. Due to its life cycle, HIV strains are accumulated and not eliminated in a sequential manner. The HIV reverse transcriptase is not unduely error prone. However an error rate of greater than one misincorporation per replicative cycle ensures that every genome is unique.

Necessarily HIV isolates must be described in terms of populations of viral genomes or quasispecies. Such studies have shown that one viral isolate was in fact a mixture of two distinct strains. Many isolates harbour high frequencies of defective genomes to the point that cultured virus probably emerged by genome complementation. Quasispecies are sensitive to selection pressures, in vitro culture being particularly selective. Thus there are striking differences between quasispecies in vivo and in vitro such that an isolate does not correctly describe the in vivo situation. Given such data it will be very difficult to describe correctly the characteristics of HIV viruses using single molecular clones. That the molecular biologist will be able to provide a molecular description of HIV induced disease seems remote, at least for the moment.

W.C.0.5 CD8+ LYMPHOCYTES ARE THE CRITICAL CELLS MEDIATING SUPPRESSION OF HIV RELEASE BY CD4+ CELLS

Wiviott, Lory, D.; Walker, C.M. and Levy, J.A. Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To determine the critical cell type responsible for the suppression of HIV replication in CD4+ lymphocytes, and define whether cell killing is a major mechanism of this suppression.
Methods: Purified CD4+ and CD8+ lymphocytes from HIV seropositive donors were prepared by the panning technique. CD4+ cells were cultured alone or with the addition of either CD8+ cells or cells prepared by CD4-depletion. Reverse transcriptase assays were done on culture supernatants at 2-3 day intervals. Cell viability counts were assessed by trypan blue exclusion. Expression of HIV proteins by the CD4+ cells was measured by indirect immunofluorescence (IFA) assay.
Results: Panned CD4+ and CD8+ lymphocyte populations were 85-90% pure by FACS analysis. Cells prepared by CD4-depletion contained 55% CD8+ cells, as well as B-cells and non-T lymphocytes. The suppressive activity of purified CD8+ cells were markedly greater than that of the CD4-depleted cells added in equal number to the CD4+ cell cultures. Neither autologous macrophages nor cells depleted of both CD4+ and CD8+ cells demonstrated suppression of HIV replication.

Cell counts and FACS analysis done at the end of 3 experiments showed no decline in the number of CD4+ cells remaining viable in cultures where suppression of HIV release had occurred. When CD4+ cells were removed by panning after exposure to HIV suppressing CD8+ cells, the percentage of cells expressing HIV antigens by IFA did not decline. Subsequent co-cultivation of these CD4+ cells with fresh, PHA-stimulated lymphocytes from a seronegative donor resulted in rapid release of infectious HIV.
Conclusion: The CD8+ lymphocyte is the critical cell mediating suppression of HIV replication by autologous CD4+ cells. Killing of the infected cells does not seem to be a major mechanism of this suppressive effect.

W.C.0.6 Infection by HIV-1 of purified NK cells with a CD3-, CD2+, CD8+, CD16+ phenotype

Daniel Scott*, Véronique Favier*, Françoise Vuillier*, Denise Guetard*, Luc Montagnier* and Guillaume Dighiero* - Unité d'Immunopathologie et Immunohématologie*- Unité d'Oncologie Virale* de l'Institut Pasteur 75724 Paris Cédex 15 - FRANCE

In a previous work, we demonstrated a significant depletion of CD8+, CD16+ NK cells in HIV infected patients (AIDS research and retroviruses 4: 121, 1988). These results prompted us to investigate the possibility that HIV could infect NK cells in vitro. Highly purified CD3+, CD4+ and CD3-CD2+, CD8+, CD16+ cell lines were obtained from peripheral blood of a patient displaying a large granular lymphocytosis; and were infected with the human immunodeficiency virus type 1 (HIV1). While CD4+ cell line displayed the well known pattern of infectivity after exposure to HIV1, in the case of CD3-, CD8+, CD16+ cell line only a transient increase of reverse transcriptase expression without increase of p-25 antigen was observed. On day 23 of culture, noninfected autologous CD4+ cells were added to HIV1 infected CD3-, CD8+, CD16+. An important and substained increase of p-25 antigen was observed 4 days after coculture, whereas in the case of reverse transcriptase an also important and substained expression was observed 10 days after CD4 adjonction. These results suggest that NK cells can be directly infected by HIV, in the presence of relatively little cytopathicity and can propagate the virus to autologous CD4 cells.

W.C.0.7 Activation and Infection of T Cells by HIV-1 Infected Antigen Presenting Monocyte/Macrophages.

Mann, Dean*, Gartner, S.**, Popovic, M.**, National Cancer Inst., Frederick*, Bethesda**, MD, USA

Objective: To investigate T cell infection and antigen presentation by HIV-1 infected monocyte/macrophage (m/m).
Methods: M/m were isolated from peripheral blood lymphocyte (PBL) from HIV-1 seronegative individuals by surface adherence and infected with HIV-1. Infected and uninfected m/m were exposed to tetanus toxin (TT) and streptokinase (Sk) for 24 hours washed, and autologous m/m depleted PBLs added. After 18 hours of exposure to m/m, T cells were removed and cultured with uninfected TT and Sk free autologous m/m. ^{3}H thymidine incorporation was determined in the T cells to assess antigen stimulation and reverse transcriptase activity measured in supernatant to monitor infection.
Results: Maximal T cell infection by HIV-1 infected m/m occurred at 7 days. HIV-1 infected m/m presented TT and Sk to autologous T cells with activation comparable to uninfected m/m. HIV-1 infected m/m stimulated and infected T cells without TT. Stimulation and infection of T cells were increased when TT was presented by HIV-1 infected m/m. MoAb to some MHC class II antigens (HLA-DR,DP) blocked T cell infection by HIV-1 infected m/m with and without TT.
Conclusion: HIV-1 infected m/m present TT and Sk to autologous T cells not unlike that seen with uninfected m/m. Activation of T cells appears to be an important component of T cell infection as antibodies that block antigen activation also block infection.

W.C.0.8 MACROPHAGE-ACTIVATING-FACTORS (MAFs) ALTER HIV-1 PRODUCTION FROM PRIMARY MONONUCLEAR PHAGOCYTES.

John Mellors, M Ortiz, N Asato, B Griffith, M Landry, J Ryan, Yale School of Medicine and VA Medical Center, West Haven, CT, USA.

Infection of mononuclear phagocytes by HIV-1 is believed to be a central event in the pathogenesis of AIDS. It is not clear, however, whether activating signals alter HIV production from these key target cells. We have studied the effects of several MAFs, including recombinant tumor necrosis factor-alpha (rTNF), interferon-gamma (rIFNg) and lipopolysaccharide (LPS), on HIV-1 production from blood monocyte-derived macrophages (MDM). MDM were purified (> 99% esterase +) from normal donors by density-gradient centrifugation and adherence to plastic in 10% human serum. After 1-2 weeks of culture, MDM were infected with HIV-1 (strain HTLV-IIIB) at a multiplicity of infection of approximately 5. Virus production was determined by ELISA of culture supernatants and cell lysates for HIV p24 antigen. Treatment of MDM with rTNF (10^2-10^3 U/ml), starting either 2 days before or 7 days after HIV-1 infection, increased virus production 5-fold over control. Treatment with LPS (1-10 ng/ml) starting 7 days after infection increased virus production 4-10 fold over control. In contrast, rIFNg (1-10^3 U/ml) inhibited HIV-1 replication (38-95% inhibition). Viral inhibition was observed irrespective of the timing of rIFNg treatment in relation to HIV-1 infection. Similar inhibition was produced by recombinant interferon-alpha$_{2a}$ or native interferon-beta, indicating that anti-HIV activity was not specific for rIFNg. These studies indicate that interferons inhibit HIV-1 replication in MDM, but that rTNF and LPS enhance virus production from these cells. These observations, combined with clinical evidence that T-cell IFNg production declines and circulating TNF levels rise with progression of HIV-1 infection to AIDS, suggest that certain MAFs may be important modulators of HIV-1 replication in vivo.

W.C.0.9 PATTERN OF HIV REPLICATION DURING IN VITRO MATURATION OF MONOCYTES INTO MACROPHAGES

Olivier René*; Chapuis F.**; Jouault T.**;Parravicini C.***; Gluckman J.C.**; Montagnier L.*.
* Unité d'Oncologie Virale, Institut Pasteur, Paris, France.
** UER Pitié-Salpétrière, Paris, France.
*** V Catt.Anat.Pat.Univ. di Milano, Ospedale L. Sacco, Italy.

Objective : Does macrophage activation control HIV replication ?
Methods : HIV replication was observed in peripheral blood monocytes and monocytic cells (THP1) cultured under various conditions to induce macrophage activation (different concentrations of human serum, phorbol ester or cytokines). Expression of differentiation cell markers : Leu M3 (monocyte specific), Pam 1 (macrophages specific), and expression of cytoplasmic viral antigens : constitutive and regulatory proteins (gp110, gp41, p18, p25, p55, p68 and nef), viral RNA, were detected at different time points after infection.
Results : HIV replication is correlated with differentiation of monocytes into macrophages and with activation of the macrophages (a study of the cell cycle indicates a high synthesis of nucleic acids). If HIV infected cultures are stimulated with heat-inactivated HIV, there is increased viral replication.
Conclusion : Expression of viral markers is correlated with monocytic differentiation. Our results suggest that a second round of viral infection could induce macrophage activation and by this way, stimulate productive HIV infection.

W.C.0.10 ADHERENT LYMPHOKINE-ACTIVATED KILLER CELL (A-LAK) CYTOTOXIC ACTIVITY AGAINST HIV INFECTED MONOCYTES.

Melder, Robert J.* **; Balachandran, R.*; Gupta, P.*; Rinaldo, C.R.*; Whiteside, T.L.* ** and Herberman, R.B.* **.
University of Pittsburgh* and Pittsburgh Cancer Institute**, Pittsburgh, PA, USA.

Objective. To characterize non-MHC restricted killing of HIV infected monocytes by a highly cytotoxic and homogeneous recombinant-interleukin-2 (rIL-2) stimulated killer cell population. **Methods**. Monocytes were infected with HIV-1 strain IIIB (H9 derived) and a monocyte-derived strain and incubated at 37°C for 1 to 7 days. Autologous and allogeneic A-LAK cultures were prepared by stimulating monocyte-depleted PBLs from normal HIV-seronegative donors with rIL-2 for 24h at 1000 U/ml and expanding the plastic-adherent population. Cytotoxicity of A-LAK cells towards HIV-infected and non-infected monocytes as well as tumor cell lines was evaluated in 4h ^{51}Cr-release assays. **Results**. A-LAK cytotoxicity against the infected and non-infected monocytes after 3 days of infection was 83 lytic units (U)/10^7 cells (strain IIIB), 364 LU/10^7 cells (monocyte-derived strain) and 17 LU/10^7 cells (non-infected monocytes). Killing of K562 and Daudi cells resulted in 8,584 and 2,008 LU/10^7 cells respectively. A-LAK killing of HIV-infected monocytes was at least 20-fold greater than fresh NK-mediated killing. A-LAK cell killing of infected monocytes (233 LU/10^7 allogeneic cells) was as effective as killing by autologous cells (74 LU/10^7 cells). **Conclusion**. A-LAK cells can express high levels of non-MHC restricted cytotoxic activity against monocytes infected with both strain IIIB and a monocyte-derived HIV strain.

W.C.O.11 INHIBITORS OF HIV-1 PROTEASE INHIBIT THE PROCESSING OF GAG AND GAG/POL POLYPROTEINS IN INFECTED T-CELLS

D. Lambert*, Meek, T.*, Dreyer, G.*, Leary, J.*, Metcalf, B.* and Petteway, Stephen R., Jr.*, Smith Kline & French Laboratories, Departments of Antiinfectives* and Chemical Sciences*, 709 Swedeland Road, King of Prussia, PA 19406-2799, U.S.A.

Processing of HIV-1 gag and gag/pol precursors into functional proteins is catalyzed by a virus-encoded protease essential for replication. The inhibition of this processing presents an unproven, yet attractive strategy, for the development of AIDS therapeutics. Here we describe that synthetic protease inhibitors are able to inhibit protease processing in infected cells. HIV-1 infected T-cells were treated with synthetic peptide analogues designed on principles of enzyme mechanism and primary protein structure and shown to be competitive inhibitors of HIV-1 protease. Western blot analysis with Mab to p24, p17 and reverse transcriptase, as well as pulse chase experiments followed by RIP with AIDS sera were used to assess processing. A significant accumulation of gag and gag/pol precursors and a decrease in the appearance of mature proteins were seen in infected cells treated with peptide analogue inhibitors relative to controls. Pulse chase experiments indicated a complete inhibition in the appearance of mature p24 at 1.5 and 3 hrs. post chase in treated cultures. These results demonstrate that peptide analogue inhibitors designed to inactivate HIV-1 protease lead to the inhibition of gag and gag/pol processing in T-cells infected with HIV-1 and support the hypothesis of viral protease inhibition as an antiviral strategy in the treatment of AIDS.

W.C.O.12 INTERACTION OF CD4 WITH gp120 OF THE HIV VIRUSES.

Sweet,Ray*,Arthos,J.*+,Deen, K.*,Axel,R.#,Hoxie,J.+,et al.
*Smith Kline & French Labs., King of Prussia, PA; +Univ. of Penn., Philadelphia, PA: #Columbia Univ., New York, NY. U.S.A.

Objective. To define and compare the gp120 binding site on CD4 for different isolates of HIV-1 and HIV-2.
Methods. We produced truncated, soluble forms of the human CD4 protein and series of site-directed substitution mutants in both bacterial and mammalian systems, quantitated their affinity for gp120 of HIV-3b by RIA and a flow cytometry assay, and measured their ability to inhibit virus binding, virus infection and virus-mediated cell fusion. For other HIV isolates the binding is being quantitated by a flow cytometry assay with infected cells.
Results. Soluble derivatives of the human CD4 receptor bind the HIV envelope protein gp120 with high affinity and in this manner block virus binding to CD4+ cells, viral infection and syncytium formation in vitro. As a result, soluble CD4 proteins are in clinical trials as potential therapeutic agents for AIDS. Through truncation and substitution mutagenesis of soluble CD4, we have defined in a quantitative manner the gp120 binding site for the 3B isolate of HIV-1. The determinants for high affinity binding occur as a single site which overlaps the CDR-2 homology region within the first variable-like domain of CD4. This predicted loop on CD4 could be accommodated by a small pocket within gp120 which may protect this site from recognition by antibodies and provide a mechanism for the virus to evade the host humoral response. HIV-2 and SIV appear to be less sensitive to inhibition by soluble CD4 in vitro. In one approach to investigating this differential sensitivity, we are defining the binding site on CD4 for isolates of HIV-2 and SIV. These results will be described.

W.C.O.13 IDENTIFICATION OF AN ATTENUATED AIDS-INDUCING FELV THAT HAS A DEFECT IN ENVELOPE PROTEIN PROCESSING.

Overbaugh, Julie*; Hoover, E.**; Mullins, J.***; Foss, M.**
*University of Washington, Seattle, WA, **Colorado State University, Fort Collins, CO, ***Harvard School of Public Health, Boston, MA - USA

Objective: To characterize the genetic differences between FeLV-immunodeficiency viruses that result in their distinct pathogenicities.
Experimental: We have identified several molecularly cloned FeLVs, obtained from a single natural isolate, that have diverse pathogenicities. The FeLVs that induce immunodeficiency in cats are all replication defective and required a helper virus for transmission. The prototype AIDS-inducing FeLV, 61C, induced disease 2-6 months following inoculation into 8-week-old cats. Another FeLV, 61B, obtained from the same cat tissue as 61C, induced disease only after a prolonged asymptomatic period of 8-20 months. The cytopathology of these viruses in feline T cells mimics their behavior *in vivo*, thus providing an *in vitro* assay to study their genetic differences. Analysis of virus chimeras indentified a defect in 61B that maps to the C' terminus of gp70 or the p15E gene. This defect in 61B results in lack cleavage of the envelope polyprotein precursor and it is responsible for the attenuated phenotype of 61B. Such results are reminiscent of observations made for attenuated strains of influenza that contain mutations at the cleavage site of the envelope precursor. Nucleotide sequence comparisons of 61B and 61C will be presented.
Conclusions: Based on studies of this natural attenuated FeLV isolate, therapies designed to interfere with proteolytic cleavage of envelope polyproteins may help to prolong the asymptomatic period in infected individuals.

W.C.O.14 SINGLE POINT MUTATIONS IN THE HIV ENVELOPE GENE ENCODING THE EXTRACELLULAR GLYCOPROTEIN AFFECT VIRAL TROPISM AND RECEPTOR BINDING.

Cordonnier Agnès, Rivière Y., Montagnier L. and Emerman M.
Unité d'Oncologie Virale, Institut Pasteur, Paris, France.

Objective: To investigate the functional significance of the domains of the envelope protein that are highly conserved between HIV-1 and HIV-2.
Methods. Short deletions or point mutations were made within the highly conserved regions of the envelope gene and the mutated genes were expressed in vaccinia virus recombinants, plasmid vectors, and/or infectious HIV proviral clones. Receptor binding was analysed by co-immunoprecipitation with soluble CD4. Supernatants from transfection of proviral clones were assayed for infectivity.
Results. *In vitro* studies revealed that the integrity of at least four domains of the envelope protein was indispensable for binding to the receptor. Detailed studies of one of these regions demonstrates that a single amino acid change can be critical for binding to CD4 molecule *in vitro*. Mutation of another highly conserved amino acid in this region did not drastically affect receptor binding but suprisingly, the tropism of the virus particles containing this mutation was modified.
Conclusion. Single amino acid changes in highly conserved regions of the envelope gene can have critical effects on receptor binding and cell tropsim.

W.C.O.15 THE EFFECT OF HIV INFECTION ON MONOCYTE DIFFERENTIATION.

Gelezinnas, Romas; Boulerice, F.; Bour, S.; and Vainberg, M.A.
Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, and Department of Microbiology and Immunology, McGill University, Montreal, Quebec, Canada.

Two monocytic differentiation markers were examined after HIV infection of U-937 cells: 1) cell surface CD4 antigen levels, 2) myc and fos oncogene mRNA quantities. First, a nearly complete depletion of cell surface CD4 was observed in HIV-infected monocytes. This is similar to the rapid and permanent down-regulation of CD4 occurring during PMA-induced differention of U-937 cells. RNA blot hybridization experiments in conjunction with immunoprecipitation assays revealed that a post-transcriptional inhibitory event is responsible for CD4 down-regulation in both HIV-infected and PMA-treated U-937 cells. Second, c-myc mRNA levels are slightly decreased, while the c-fos mRNA precursor is more abundant in chronically infected U-937 cells, suggesting a possible mRNA processing defect in HIV-infected monocytes. These studies show that HIV may be modulating certain events leading to terminal monocyte differentiation.

W.C.O.16 EVIDENCE THAT CD4(81-92) MAY CONSTITUTE A UNIQUE BINDING EPITOPE FOR HIV ENVELOPE GLYCOPROTEIN/CD4 INTERACTION.

Kalyanaraman, V.S.*; Lifson, J.**; Hwang, K.**; Padgett, M.***; Rausch, D.***; Eiden, L. ***. *Bionetics Research Incorporated, Rockville, MD, USA, **Genelabs, Incorporated, Redwood City, CA, USA, ***LCB, NIMH, Bethesda, MD, USA.

Objective. To demonstrate the anti-viral mechanism of action of CD4(81-92)-based antireceptor peptide in HIV-1 viral glycoprotein/CD4 cellular and solubilized-CD4 binding assays.
Methods. The binding of iodinated gp120 to CD4-positive CEM-SS cells, the binding of metabolically labeled gp120 to the CD4 receptor on CEM-SS cells, and the binding of gp120 to CD4 solubilized from CEM-SS cells was measured directly (iodinated gp120) or by radioimmunoprecipitation with OKT4 (Kalyanaraman et al., *ibid.* 4:319, 1988). The ability of various CD4-derived peptides to inhibit gp120 binding in both assays was compared to the potency of CD4-derived peptides to inhibit HIV-induced cell fusion and HIV-1 infection of CD4-positive CEM-SS cells (see Eiden et al., this volume).
Results. The concentrations of each peptide required to give 50-100% inhibition in each assay are given:

Peptide	gp120/CD4binding	Cell fusion	HIV-1 Infection
CD4(81-92)BZL(peak 7)	7.8-31 µM	<32 µM	<10 µM
TbYIChEbVEDQKEE	31-62 µM	32 µM	31-63 M
TbYIChEbVEDQKEEalk	15-62 µM	16 µM	10-30 µM
KEEIChEbVEDQTbY	>250 µM	>500 µM	>250 µM
TbYIChEVEbDQKEE	>250 µM	>500 µM	250 µM
CD4(23-56)	no inhibition	>500 µM	>250 µM

Note: b=benzyl ester or ether, alk=residue-specific monoalkylation
The peptide CD4(23-56) completely inhibited OKT4A blockade of gp120/CD4 binding at 125 µM.
Conclusions. There is a good concordance for potency to inhibit gp120/CD4 binding, HIV-1 induced cell fusion, and HIV-1 infection, suggesting that the mechanism of action of CD4(81-92)-derived peptides is direct inhibition of gp120/CD4 interaction. CD4(23-56) may contain the epitope through which OKT4A inhibits CD4/gp120 binding, but not the gp120 binding epitope itself.

Mise au point de vaccins contre le SIDA
Vaccine Developments in AIDS

W.C.0.17 CURRENT TRENDS IN HIV VACCINE PREPARATION

Marc Girard, Pasteur Vaccins and Institut Pasteur, Paris, France.

The development of a vaccine against AIDS has met with considerable difficulties. Not only does the virus remain latent in the body for long periods of time, probably persisting as an integrated provirus in the genome of the host cell, but it also shows considerable genetic variability. For an HIV vaccine to be able to prevent infection, quick neutralization of the virus would be of crucial importance. However, neutralizing antibodies raised against an HIV-1 isolate do not usually cross-neutralize other HIV-1 isolates. Work on a vaccine is further hampered by the fact that the only animal model system available so far for HIV-1 uses the chimpanzee. Following infection the animals replicate the virus and become asymptomatic carriers with no signs of disease. Finally, the HIV envelope glycoprotein appears to be poorly immunogenic. It elicits only weak neutralizing anti-viral antibody titers, perhaps due to epitopic suppression. In our hands, vaccinia virus HIV recombinants elicited a T-cell immune response but only a weak humoral response. An inactivated virus vaccine elicited a good humoral immune response but no T-cell response. Purified HIV antigens added with a MDP-base adjuvant showed however high immunogenic potency. Finding the appropriate presentation of HIV antigens able to elicit high neutralizing antibody titers of broad reactivity is a requisite for the successful development of an HIV vaccine.

W.C.0.18 DEVELOPMENT OF AN HIV SUBUNIT VACCINE

Putney, Scott D.*; LaRosa, G.*; Javaherian, K.*; Emini, E***; Bolognesi, D.**; and Matthews, T.**; *Repligen Corporation, Cambridge, MA, USA, **Duke University Medical School, Durham, NC, USA, ***Merck, Sharp and Dohme Research Laboratories, West Point, PA, USA.

We have mapped the principal HIV neutralization determinant to a disulfide loop in a variable region of the outer envelope (aa 303-338). Antibodies elicited by peptides as small as eight amino acids from the center of this determinant neutralize free HIV and prevent fusion of HIV infected cells with uninfected CD4 cells. These antibodies are type-specific in that antibodies elicited by a peptide of the sequence from one isolate do not neutralize a panel of divergent HIV-1 isolates.

Using PCR amplification and sequencing of this determinant from independent HIV-1 isolates, we have found that over 40 of 100 randomly isolated viruses have identical or very similar amino acid sequences. In addition, over 80 of 100 sera from randomly selected HIV-1 infected people react with a peptide of this sequence. This indicates that viruses with this amino acid sequence are prevalent. This data,taken along with data that antibodies to this determinant delays HIV infection of chimpanzees, (E. Emini, et al.) suggests that a broadly protective HIV subunit vaccine can be developed.

W.C.0.19 IMMUNISATION EXPERIMENTALE ANTI HIV CHEZ L'HOMME

Zagury, Daniel

Dans le cadre d'une coopération de recherche Franco-Zaïroise, des essais d' immunisation active anti HIV, destinés à préparer un vaccin anti-SIDA, par l'induction d'une immunité à médiation cellulaire, ont été engagés depuis novembre 1986 chez des volontaires séro-négatifs. Ces essais (1-2), précédés d'une expérimentation chez l'animal qui a montré l'innocuité et l'immunogénicité des préparations utilisées, ont comporté une primo-injection de vaccine recombinante (Vr) exprimant la protéine gp 160 du HIV_1 et un rappel variant suivant les individus (Vr ; segment de protéines virales purifiées; cellules autologues infectées par le Vr et fixées à la paraformaldéhyde ; membranes autologues isolées exprimant des signaux du virus). Le protocole d'immunisation Vr + cellules autologues infectées et fixées peut être considéré comme un candidat vaccin puisqu'il induit une réaction anti HIV anamnestique et spécifique de groupe (2-3) avec des cellules tueuses et des anticorps qui sont protecteurs- et non facilitants- vis à vis de l'infection par le HIV_1 des monocytes/macrophages in vitro (4).

Nous recherchons actuellement un protocole d'immunisation reproduisant le même état d'immunité anti HIV que le prototype et plus simple à administrer à un grand nombre d'individus. Cette étape dans le développement d'un vaccin anti SIDA est indispensable avant d'envisager un essai clinique à plus grande échelle (phase 2) susceptible d'évaluer le niveau de protection vis à vis de l'infection naturelle du candidat vaccin.

Drug Development: Novel Study Approach to Anti-Viral Drugs

W.C.O.21 INHIBITION OF HIV-1 PLAQUE FORMATION BY A NOVEL CLASS OF MEMBRANE-ACTIVE ETHER LIPID ANALOGS

Kucera, Louis*; Iyer, N.*; Raben, A.*; Modest, E.*; Daniel, L.* and Piantadosi, C.**.
*Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC, USA; **University of North Carolina, Chapel Hill, NC, USA.

Objective. We characterized the *in vitro* anti-HIV-1 activity of membrane-targeted DNA non-interactive ether lipid (EL) analogs of platelet activating factor. Methods. Human CEM-SS cell monolayers were used to determine effects of structural modifications of Type A phosphorus containing and Type B nonphosphorus EL analogs on the inhibitory dose$_{50}$ (ID_{50}) for (a) HIV-1 syncytial plaque formation, (b) cell growth (^{3}H-TdR incorporation into DNA), and (c) protein kinase (PKC)activity. Results. Type A ET-18-OMe and Type B CP-7 (ID_{50}=1.5μM) inhibit HIV-1 plaque formation when added before and at least 2 days after viral infection. Initial data indicate that CP-7 inhibits HIV-1 but not herpes simplex virus plaque formation. Anti-HIV-1 activity does not involve direct inactivation of infectious virus. Type A ether phospholipids (ID_{50} range = 0.2 to 1.1 μM) with a thioalkyl or amidoalkyl moiety at glycerol position-1 and ethoxy or methoxy group at position-2, and Type B compounds (ID_{50} range=<0.62 to 0.75 μM) with an inverse choline at position-3 have anti-HIV-1 activity. The anti-HIV ID_{50} values are 5 to 20-fold below the ID_{50} for cell growth. Also, anti-HIV-1 EL inhibit PKC. Conclusion. These data indicate that EL analogs are a novel class of potential therapeutic agents against the etiologic agent of AIDS and, being membrane-interactive, are ideally suited for combination chemotherapy with anti-HIV nucleoside analogs.

W.C.O.22 GENERATION OF INDICATOR CELL LINES FOR THE FAST ASSAY OF HIV-1 AND FOR THE STUDY OF ANTIVIRAL DRUGS.

Pavlakis, George N. & Felber, B.K.
NCI-FCRF, BRI-Basic Research Program Frederick, MD 21701 USA

Objective. To generate a fast and quantitative method for the in vitro assay of infectious HIV-1 on human T cells and monocytes. To use this methodology for the study of various HIV isolates and for measuring the effects of drugs and drug combinations on HIV-1 infectivity and replication.
Methods. Retroviral vectors were used to construct stable $CD4^{+}$ human cell lines containing the HIV-1 LTR linked to the convenient reporter genes chloramphenicol acetyltransferase (CAT) or alkaline phosphatase (SEAP).
Results. Uninfected indicator cell lines produce very low levels of the reporter enzyme. Upon infection by HIV-1 the produced tat protein activates expression of the LTR resulting in high levels of CAT in the cytoplasm, or SEAP in the medium of the infected cells. The effects of drugs or drug combinations can be studied quantitatively 2-3 days after infection by 96 well-based chromogenic assays, which detect CAT or SEAP. These convenient assays have also been used to quantitate gene expression after transient transfections of eucaryotic cells. Indicator cells derived from T cells or monocytes were affected differently after infection by HIV-1.
Conclusion. A sensitive and specific bioassay for HIV-1 was used to quantitate the effects of drugs and drug combinations on HIV-1 infectivity and replication.

W.C.O.23 MECHANISM OF ACTION OF SULPHATED POLYANIONS AS INHIBITORS IN HIV INFECTION IN VITRO

L. Low,. C. Parish. B. Warren. J.M. Mathije. F. Kazazi and A.L. Cunningham. Virology Unit. Westmead Hospital. Westmead. Sydney. Department of Virology and Cellular Pathology. John Curtin School of Medical Research and Cancer Research Institute. Woden Valley Hospital.
AUSTRALIA

A wide range of sulphated polyanions has been examined for inhibition of HIV infection of MT4 lymphoblastoid cell lines by wild and laboratory strains of HIV. as detected by cytopathic effect and extracellular HIV antigen levels at 6-8 days. The most potent inhibitors were dextran sulphate. polyanethole sulphonate and pentosan sulphate (ID50=10 and 1ug/ml respectively. antiviral index >1000 for all compounds). Fucoidin sulphate. polyvinyl sulphate iota-carrageenan and dextran sulphate 5000 were less potent (ID50=100ug/ml). Potency of these compounds was increased by using serum depleted of polyanion binding proteins in the cell culture medium. Fucoidin sulphate. polyanethole sulphonate polyvinyl sulphate and a dextran sulphate 500.000 (not D.S.5000) inhibited binding of 11/12 anti-CD4 monoclonal antibodies (including anti-OKT4a but not anti OKT4) to T cells. However 20 anti CD8 monoclonal antibodies did not inhibit binding. Therefore a correlation between inhibition of anti OKT4a binding and HIV infection was demonstrated. with the exception of pentosan sulphate and the small dextran sulphate polymer. These anomalies are probably caused by the ability of these smaller polyanions to inhibit binding of large viral particles but not highly specific monoclonal antibodies. In addition. we have not been able to demonstrate binding of radio-labelled partially (lentil lectin) purified native gp120 to dextran sulphate immobilised on fibres.Competition between residual cell glycoproteins and gp120 is most unlikely because of the excess capacity of the polyanion conjugated fibres. Hence these sulphated polysaccharides may bind to basic amino acid residues in the first two domains of CD4. in close apposition to the gp120 binding sites.

W.C.O.24 COLCHICINE INHIBITS HIV-1 IN VITRO

Read, Stanley*, Lyons, M.**,Li, H.*,and Zabriskie, J.**
*University of Toronto, Toronto, Canada and
**Rockefeller University, New York, USA

Objective: To determine whether colchicine, at levels achievable in serum, inhibits replication of HIV-1.
Methods: Colchicine at 10, 1 and 0.1 μmoles was added to CEM and HUT cell lines previously infected with HIV-1, as well as to a continuously infected H9 cell line. Viral replication was measured by reverse transcriptase (RT) and p24 antigen capture. Cell counts were carried out to determine the effect of colchicine on cell replication.
Results: Inhibition of HIV replication was observed in all infected cell lines at all 3 concentrations of colchicine. At 1 and 0.1 μmoles of colchicine there was minimal inhibition of cell replication. Pretreatment of HUT and CEM cell lines prior to adding HIV, without maintaining colchicine in the medium, appeared to delay infection/replication for at least 16 days.
Conclusions: Colchicine inhibits HIV-1 replication in vitro at concentrations achievable by oral doses which are clinically tolerated by most individuals.

W.C.O.25 Structures Necessary for HIV-1 Entry:

Weiner, D.B.*, Williams, W.V.*, Hoxie, J.A.*, Hubner, K.**, Berzofsky, J.A.***, Greene, M.I.*.: *University of Pennsylvania, Philadelphia, PA, USA, **Wistar Institute, Philadelphia PA, USA, ***NIH, Bethesda, MD, USA.

Objective: To define and and analyze at the molecular level HIV-1 envelope structures and human cell structures mediating virus entry.
Methods: We have focused on the molecular definition of fusion/entry structures using novel fusion blocking reagents as well as molecular reagents and interspecific hybridomas. Conclusions: We report here that CD4 expression is not sufficient for HIV-1 entry mechanisms. We have developed antisera which specifically interacts with structures ancillary to molecules which are important in HIV-1 entry. Characterization of these proteins as well as viral epitopes necessary for entry functions have been performed.
Results: Studies have demonstrated that HIV-1 virus entry is not mediated through receptor mediated endocytosis but occurs directly though virus fusion events localized at the plasma membrane. Furthermore CD4 function on the murine background is essentially similar to function on the human background. We have utilized this species trophism to begin to determine the chromosomal position of the ancillary molecules necessary for HIV-1 entry. We have utilized antisera which disrupts post binding events of HIV-1 to epitope map regions of HIV-1 that may have protective value in immunization strategies. We have also developed antisera to characterize secondary structures for HIV-1 entry. The utility of these structures for immunological manipulations which productively alter HIV induced pathogenesis is under investigation.

W.C.O.26 IDENTIFICATION AND CHARACTERIZATION OF COMPLEMENT-MEDIATED ENHANCEMENT OF HIV-1 INFECTION BY MANNOSIDASE I AND II INHIBITORS

Montefiori, David C., Robinson, W.E., Jr., Modliszewski, A. and Mitchell, W.M. Vanderbilt University, Nashville, TN, U.S.A.

Objective. To study the effects of human serum on HIV-1 infection *in vitro* using virus synthesized in the presence and absence of glycoprotein carbohydrate processing inhibitors.
Methods. HIV-1 was produced in H9/HTLV-III$_B$ cells in the presence and absence of inhibitors, then used to examine the effect that various sera, monoclonal antibodies (MoAbs) and sialidase had on infection of MT-2 cells. Infections were monitored by cytopathic effect, antigen synthesis and reverse transcriptase release.
Results. Fresh human serum enhanced infection when virus was synthesized in the presence of 1-deoxymannojirimycin or swainsonine but had no enhancing effect on virus synthesized in the presence of castanospermine, 1-deoxynojirimycin or bromoconduritol. Enhancement was also observed in the presence of sialidase and in C1q-deficient serum but not in serum that was heat-inactivated or depleted of complement components C3 or factor B. Enhancement did not allow infection in the presence of MoAb against CD4 (OKT4a) and was blocked specifically by monoclonal antibody against CR2 (OKB7).
Conclusions. Infection of $CD4^{+}$ lymphocytes by HIV-1 is enhanced by some agents that may cause the accumulation of high mannose-type, non-sialylated HIV glycoproteins. This enhancement appears to require the alternate pathway of complement, CD4 and the complement component C3d receptor, CR2.

Animal Models (Part 2)

W.C.O.27 EVALUATION BY PCR OF HIV-1 STATUS OF CHIMPANZEES CHALLENGED WITH HIV AFTER RECEIVING HUMAN HIVIG

Hewlett,* Indira K., Epstein, J.S., Hawthorne, C.A. Eichberg,*** J., and PRINCE,** A.M.
Food and Drug Administration,* Bethesda, MD. 20892, New York Blood Center NY** and Southwest Foundation, TX.*** U.S.A.

Objective. To determine the status of HIV after virus challenge in chimpanzees previously immunized with HIVIG.
Methods. Five chimpanzees were passively immunized with HIVIG prepared from plasma of HIV asymptomatic, seropositive donors whose serum contained high titers of neutralizing antibodies (Prince et al PNAs, Vol 85 p. 6944-6948) Virus isolation was performed on peripheral blood mononuclear cells (PBMCs) by coculture. PCR was performed on DNA isolated from lymphocytes, using the gag and env primers for confirmatory detection.
Results. HIV-1 DNA sequences were detected by PCR in lymphocytes of all of the animals after virus challenge although virus cultures were not positive until 3-9 weeks after challenge.
Conclusion. Administration of HIVIG to chimpanzees was unable to prevent HIV infection. Virus expression (RNA-PCR in PBLs) and release of assembled virus in serum (PCR on serum) are being performed to assess virus activity in these animals.

W.C.O.28 THE MURINE ACQUIRED IMMUNODEFICIENCY SYNDROME (MAIDS) IS CAUSED BY A DEFECTIVE RETROVIRUS

Huang, Ming*; Hanna, Z.*; Aziz, D.*; Simard, C.* and Jolicoeur, P.*,**.
*Clinical Research Institute of Montreal, Montreal, Quebec, Canada;
**Université de Montréal, Montreal, Quebec, Canada.

The Duplan strain of murine leukemia virus (MuLV) induces MAIDS, a disease showing striking similarities with human AIDS. We identified the etiologic agent of the disease as being a defective retrovirus having a 4.8 kbp genome. Sequencing of this DNA showed that the pol and env genes have been deleted and that the complete gag region has been conserved and harbors a novel p12 sequence. Using a cell-free translation system, the genome has been shown to encode a 60 kd gag fusion protein. The same protein was detected in non-producer cells harboring the defective genome and is not cleaved. N-tropic pseudotypes have been constructed with this virus and the role of helper virus in the disease is also being investigated using the Ψ2 encapsidation-negative system. This mouse model emphasizes the need to search for pathogenic defective retroviruses in AIDS.

W.C.O.29 EFFECTS OF SPERM AND AUTOIMMUNITY ON MURINE AIDS (MAIDS)

Bentwich, Zvi H.*; Weisman, Z.*; Meshorer, A.**; Rubinstein, J.** and Mozes, E.***
*R. Ben Ari Institute of Clinical Immunology, Kaplan Hospital, Hebrew University Medical School, **Experimental Animal Unit, ***Department of Chemical Immunology, The Weizmann Institute of Science, Rehovot, Israel

Objective. To determine the effect of sperm and induced autoimmune disease on the generation and course of MAIDS.
Methods. Disease was induced by viruses obtained from cell line LP-BM5-Scl in male C57BL/6J, B10A, ATL and ATH strains. Allogeneic sperm cells (1-3 x 10^7) were injected intravenously prior to and following the viral inoculations. Experimental SLE-like disease was induced by a human monoclonal anti DNA antibody termed 16/6. Serial serum immunoglobulin levels, cellular proliferations and histopathological examinations were performed.
Results. Splenomegaly in several animals and prolonged suppression of splenocyte proliferation to mitogens and allogeneic stimulation were observed following single sperm injection into normal animals. Sperm enhanced significantly the induction of MAIDS by the viral preparations, which was more evident when using subminimal doses of virus.

	Saline	Sperm	Virus	Virus + Sperm
MAIDS	0/18	0/19	2/19	10/19

16/6 antibody injection to virus inoculated animals increased serum levels of Ig, anti DNA and anti idiotypic antibodies and immunopathology.
Conclusion. Immunomodulation by sperm and autoimmune disease influences the course of MAIDS. This may have direct relevance to their role in the pathogenesis of human AIDS.

W.C.O.30 MOLECULAR CLONING AND SEQUENCE ANALYSIS OF FELINE IMMUNODEFICIENCY VIRUS (FIV)

Olmsted, Robert A.*, Barnes, A.K.**, Yamamoto, J.K.***, Hirsch, V.*, Purcell, R.H.**, and Johnson, P.R.* *Georgetown Univ., Rockville, MD; **NIAID, NIH, Bethesda, MD; ***Univ. of California-Davis, U.S.A.

Objective. FIV is a T-lymphotropic retrovirus that is associated with immunodeficiency and opportunistic infections in cats and provides an excellent opportunity for the development of a small animal model for AIDS. To initiate these studies, we isolated a proviral clone of FIV for molecular and biological characterization.
Methods/Results. FIV-Petaluma cDNA clones were synthesized and used to isolate the proviral molecular clone, FIV-14. Molecular cross-hybridization analysis of FIV-14 with 5 lentiviruses revealed that nucleotide sequence similarities exist between FIV and these viruses in the gag-pol genes. Significant nucleotide sequence identity was observed between the 5' 1.5kb of the FIV-14 pol gene and the pol genes of SIV, HIV-2, HIV-1, EIAV, visna virus and CAEV (55% to 65% identity). Sequence similarities were not observed upon comparison of the FIV LTR sequence with known viral sequences. Common antigenic determinants appeared to be shared by FIV, CAEV, and visna virus as shown by serological cross-reactivity of rabbit antibodies to CAEV and visna virus with the putative FIV core protein, p28. Importantly, progeny virions of FIV-14 were infectious for experimentally inoculated cats.
Conclusions. These studies demonstrated that FIV is a member of the lentivirus subfamily and is distantly related to the AIDS lentiviruses of primates. The availability of an infectious molecular clone will make possible a detailed dissection of the molecular pathogenesis of FIV, which may facilitate the development of vaccine and therapeutic strategies for AIDS.

W.C.O.31 T-CELL KILLING BY THE FeLV-FAIDS IMMUNODEFICIENCY VIRUS

Peter R. Donahue[1], E. A. Hoover[2], C.M.C. deNoronha[1], S. L. Quackenbush[2], J. Overbaugh[1*], and J. I. Mullins[1]. (1)Harvard School of Public Health, Boston, MA, (2)Colorado State University, Ft. Collins, CO, (*)Present Address: Univ. of Washington, Seattle, WA, U.S.A.

OBJECTIVE: Locate the genetic determinant(s) and elucidate some aspects of the mechanisms of T-cell killing by a molecularly cloned feline leukemia virus that induces fatal immunodeficiency disease in outbred specific-pathogen-free cats.
METHODS: Chimeric viruses were generated in vitro using the replication competent nonimmunosuppressive 61E provirus and the replication defective acutely immunosuppressive 61C provirus. To assess their pathogenicity, an in vitro assay using a feline T-cell line was developed.
RESULTS: Replication competent chimeras were obtained that were T-cell cytopathic in vitro and induced immunodeficiency disease in vivo. Analysis of 22 chimeras revealed that the essential determinant for T-cell killing resides within a 21 base pair (7 amino acid) stretch within the extracellular glycoprotein gene (gp70), corresponding to a single amino acid change and a 6 amino acid insertion in the protein. Other changes within gp70 and the viral LTR enhance the efficiency and rate of T-cell killing in vitro and pathogenicity in vivo. T-cell killing occurs along with production of high levels of unintegrated viral DNA and viral mRNA, and can be blocked by exposing newly infected cells to antisera from cats exposed to the virus.
CONCLUSION: These findings suggest that T-cell killing occurs as a result of massive superinfection and that the critical mutations in gp70 cause a failure or delay in the establishment of superinfection interference, possibly through altered interactions with p15E and/or its cellular receptor.

W.C.O.32 INFECTION OF THE NEW ZEALAND WHITE LABORATORY RABBIT (ORYCTOLAGUS CUNICULUS) WITH HIV-1

Reina. S.*'**, Markham, Phillip D.***, Gard, E.A.***, Ford, G.***, Buchbinder, A.*, Gallo, R.C.*, et al. *National Cancer Inst., NIH, Bethesda, MD, **Visiting from Inst. Microbiol., Genova, Italy, ***Bionetics Research, Inc., Rockville, MD, U.S.A.

Objective: To develop a laboratory model for HIV infection of NZW rabbits.
Methods: NZW rabbits were injected intraperitoneally with HIV-1 or HIV-1-infected cells after thioglycollate-induced peritonitis. Animals were monitored for physical and hematological abnormalities, infectious virus, viral nucleic acids, and antibodies to viral proteins.
Results: Three rabbits inoculated twice at 60 day intervals with HIV-1 produced continuously rising titers to both gag and env proteins. Virus, detected as viral antigens, was also periodically recovered from peripheral blood leukocytes by cocultivation with susceptible cells. Persistent infection was also suggested by detection of proviral DNA in multiple tissues. Physical abnormalities included lymphadenopathy and pulmonary rales. Histopathology revealed a disruption of follicular architecture of lymph nodes.
Conclusion: NZW rabbits appear to be infectable with HIV-1 and demonstrate a pathological effect. However, much work remains in characterizing this potential animal model.

Virology (Part 3)

W.C.0.33 ANALYSIS OF T CELL NUCLEAR FACTORS WHICH BIND TO THE NEGATIVE REGULATORY ELEMENTS (NRE) OF THE HIV LTR

Guy, Bruno ; Acres, B. and Kieny, M.P.
TRANSGENE S.A., 11 Rue de Molsheim, 67082 Strasbourg Cedex, FRANCE

Objective. To analyse the nuclear factors binding to the NRE sequence of the HIV LTR and to investigate the influence of nef on these factors.
Methods. Gel retardation assays and methylation interference techniques have been used.
Results and Conclusion. Nuclear extracts from human E rosette positive peripheral blood cells and from T cell clones were analysed using gel retardation assays. NRE binding factors were detected and their appearance in the nucleus is associated with activation of the cells. Moreover, NRE binding factors in nuclear extracts prepared from cells stimulated with PHA ± TPA appear to be different from that (those) which appear in response to IL-2. At least one of the factors is down regulated when the HIV nef gene is expressed in cells using a vaccinia virus expression system.
Evidence will be presented which demonstrates associations between the appearance of HIV NRE binding factors and genetic elements involved in T cell activation.

W.C.0.34 FUNCTIONAL ROLE OF HIV-1 VPU

Cohen, Eric A.; Terwilliger, E.; Sodroski, J.; Haseltine, W.
Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA U.S.A.

Objective: Determination of the effect of the vpu gene of HIV-1 upon the viral life cycle.

Methods: Isogenic HIV-1 proviruses identical except for possessing a functional vpu were constructed and transfected into CD4+ Jurkat cells. Parameters of virus infection quantitated included cell number, syncytia formation, supernatant reverse transcriptase activity, and both cell and virion associated viral protein levels.

Results: Cells infected with vpu-expressing virus demonstrated a marked increase in the ratio of virion associated versus cell associated viral protein compared to cultures infected with vpu-negative virus. The vpu-positive cultures exhibited lags in syncytium formation, cell death and accumulation of intracellular viral proteins, despite possessing higher levels of supernatant reverse transcriptase activity.

Conclusion: The product of vpu acts to accelerate virus export.

W.C.0.35 EFFECTS OF MUTATIONS IN THE nef GENE ON THE GROWTH OF HIV.

Kim, Sunyoung*, Ikeuchi, K.**, Byrn, R.**, Groopman, J.**, and Baltimore, D.*
* Whitehead Institute, and Dept. Biology, MIT, Cambridge, MA, USA.
** New England Deaconess Hospital, Harvard Medical School, Boston, MA, USA.

HIV contains the open reading frame called nef at the 3' end of its genome which was reported to be dispensable for viral growth but to reduce viral gene expression. We have compared two different HIV-1 strains with the same genetic background, except for a lesion in nef; one containing the complete coding region, and the other null for nef. The effects of nef on various stages of HIV infections were examined. We have tested effects on viral entry, DNA and RNA synthesis by examining HIV-specific low molecular weight DNA and RNA after infection. Comparable results were obtained from both nef^{+} and nef^{-} strains. The effects on viral growth were also tested by following changes in reverse transcriptase activity in cell culture supernatant and the fraction of infected cells (determined by indirect immunofluorescence) during the course of infection. The presence of the nef gene product fails to slow down viral growth in many different cell types tested, including human T lymphocyte cell lines, H9 and CEM, human primary T cells, and human monocytic cell lines such as U937 and THP-1. These results were reproducible with the use of a different virus isolate. Our data suggest that nef does not act as a negative factor, at least in the experimental system we employed.

W.C.0.36 VPU - A PROTEIN UNIQUE FOR HIV-1 IS REQUIRED FOR EFFICIENT VIRION MATURATION AND RELEASE

Klimkait, Thomas*; Strebel, K*; Orenstein, J**; Martin, M.A*
*Laboratory of Molecular Microbiology, NIAID, NIH, Bethesda, MD, USA
**George Washington University Medical School, Washington, DC, USA

Objective: To determine the role of HIV-1 vpu and its intracellular location during productive viral infection of human T-cells.
Methods: Infections of T-lymphocytes with virus particles derived from an infectious molecular clone of HIV-1 or a deletion mutant lacking the vpu gene were compared. A monospecific vpu antiserum was used in indirect immunofluorescence assays for the cellular localization of vpu. Morphological changes associated with wild type or vpu mutant infections were examined by electron microscopy.
Results: Wild type or vpu mutant virions have similar infectivity in human T-cells. However, infections with the vpu mutant resulted in earlier cell fusion and cell death, both of which paralleled the intracellular accumulation of viral proteins. Using indirect immunofluorescence assays, vpu was localized to the cytoplasm of infected cells; no vpu was detected in the nucleus or on the outer surface of the plasma membrane of virus producing T-cells. Electronmicroscopic analysis of cells infected with the vpu mutant revealed the presence of virus-like particles in the cytoplasm, intracellular budding, and an accumulation of immature particles at the cell surface; these features were not observed in cells producing wild type virions.
Conclusions: Vpu is required for the efficient release of HIV-1 particles from productively infected lymphocytes. The absence of vpu results in an intracellular accumulation of virus particles and impairs virus maturation.

W.C.0.37 EFFECTS OF NEF EXPRESSION ON HIV REPLICATION AND CELLULAR FUNCTIONS

Cheng-Mayer, Cecilia; Iannello, P. Luciw, P.A.* and Levy, J.A.
Cancer Research Institute, University of California, San Francisco, CA 94143 USA, *Department of Medical Pathology, University of California Davis, Davis, CA 95616 USA

Objective. To determine the effects of stable nef expression on HIV replication and cellular functions.
Methods. Stably transformed cell lines expressing the nef protein were obtained by transfection of HUT-78, RD (human rhabdomyosarcoma) and COS-7 (monkey) cells with plasmid constructs of nef under the SV-40 or HIV-LTR promotors. Expression of nef was monitored by an immunofluorescence assay (IFA) and immunoblot analyses. Effects of nef expression on HIV replication was assayed by transfection and infection of these stable cell lines. Effects on cellular function were monitored by cell growth and modulation of cell surface markers.
Results. Stable cell lines expressing the nef gene product, p27, were obtained in HUT-78, RD and COS cells. Expression of nef in HUT-78 results in the down-modulation of the CD4 receptor molecule. This down-modulation appears to be specific since other cell surface markers, e.g. CD3, were not affected. Expression of nef in HUT-78 also leads to the suppression of HIV replication upon transfection or infection with HIV. In some stably transformed cell clones, the expression of nef appears to retard cell growth. This is similar to that observed for ras expression in yeast. Current studies are directed at elucidating the mechanisms by which nef regulates HIV replication and cellular function. Its interaction with other HIV regulatory proteins is also being examined.
Conclusion. Expression of nef in stably transformed cell lines has been shown to suppress HIV replication and affect cellular functions. These cell lines will be used to understand the mechanism by which the nef protein exerts its effects, and the interactions it has with the other HIV regulatory proteins.

W.C.0.38 IN VITRO GENERATION OF NEUTRALIZATION-RESISTANT HUMAN IMMUNODEFICIENCY VIRUS (HIV)

Harada, Shinji*; Masuda, T.*; Kannagi, M.*; Matsushita, S.** and Takatsuki, K.**. *Institute for Virus Research, Kyoto University, Kyoto, 606 Japan. **Kumamoto University Medical School, Kumamoto, 860 Japan.

Objective. To prove that HIV produces antigenic variation in the presence of neutralizing monoclonal antibody (0.5β).
Methods. Plaque-cloned HIVs and monoclonal antibody (0.5β) which shows type-specific neutralization were used. The virus-infected MT-4 cells were cultured with or without 0.5β for 1 month to obtain variants of the virus. To know the antigenic changes of the viral envelope, we performed plaque-assay for neutralization and radioimmunoprecipitation assay. Restriction enzyme map analyses were used to show the genetic changes.
Results. After 1 month of culture, we obtained variant viruses which showed cytopathic effects even in the presence of 0.5β. Neutralization test by 0.5β revealed that antigenic differences between control and variant were marked. Also, 0.5β precipitated gp120 of control but not of variant. Restriction enzyme map analyses showed that there were no differences among them.
Conclusion. We showed that the alteration in virus neutralizability was observed in the presence of neutralizing monoclonal antibody, suggesting that this antibody may exert selective pressure. Restriction enzyme map analyses indicate that the changes at genetic level might be a minor one. Probably a point mutation was proposed.

Éléments de base en immunologie (partie 2)
Basic Immunology (Part 2)

W.C.O.39

ANALYSIS OF THE FUNCTIONAL DEFECTS OF T LYMPHOCYTES IN HIV-INFECTED PATIENTS. Pantaleo, Giuseppe, Koenig, S., Baseler, M., Lane, H.C., and Fauci, A.S. LIR, NIAID, NIH, Bethesda, MD. U.S.A.

Objective. To understand the pathogenesis of in vitro proliferative defects of $CD4^+$ and $CD8^+$ T lymphocytes from HIV-seropositive patients.
Methods. Phenotypic analysis of peripheral blood mononuclear cells (PBMC) from 243 HIV seropositive individuals was performed by fluorescence cytofluorometry using a panel of monoclonal antibodies (mABs) recognizing T cell, B cell, and monocyte cell surface antigens. Two-color cytoflurometric analysis was also performed using anti-CD3, anti-CD4, anti-CD8, anti-HLA-DR and anti-TAC on PBMC from some of these patients. Unfractionated PBMC and T cell subpopulations were cloned using a limiting dilution microculture system to determine the frequency of proliferating T lymphocytes precursors (PTL-P).
Results. In the fluorometric analysis we found an increased number of DR^+ T cells in PBMC of 50 of our patients. The majority of DR^+ cells were $CD8^+$ (~80%), whereas ~ 20% of DR^+ cells were $CD4^+$. However, TAC antigen was not expressed on these DR^+ $CD8^+$ or DR^+ $CD4^+$ T cells. Stimulation of sorted $CD8^+$ DR^+ and $CD8^+$ DR^- cells with anti-CD3 mAB in solid phase showed that in contrast to $CD8^+$ DR^- cells, $CD8^+$ DR^+ cells failed to proliferate even when exogenous IL-2 was added. The proliferative defect of $CD8^+$ DR^+ T cells was further confirmed by limiting dilution clonal analysis.
Conclusions. We provide evidence suggesting that the in vitro proliferative defect of T cells in patients with AIDS may be due in large part to an in vivo expansion of non clonogenic populations of T cells.

W.C.O.41

DETERMINATION OF EPITOPES RECOGNIZED BY HIV-SPECIFIC CTL. Koenig, Scott, Earl, P., Wood, L., Powell, Moss, B., Fauci, A.S. et al. LIR, and LVD, NIAID, NIH, Bethesda, MD, U.S.A.

Objective. To identify group specific epitopes which stimulate HIV-specific cytotoxic T cell responses (CTL).
Methods. Fresh peripheral blood mononuclear cells (PBMC) and T cells cloned by limiting dilution from HIV-1 seropositive patients and participants in a Phase I vaccine clinical trial using recombinant gp160 served as effector cells in these studies. HIV-specific CTL activity was determined using lymphoblastoid target cells (LCL) infected with recombinant vaccinia viruses (rVV) expressing envelope, gag, or pol HIV-1 proteins in a 4 hour ^{51}Cr release assay. Truncations of the envelope and pol genes were also expressed in rVV to define specific regions stimulating CTL responses. Synthesized peptides were used to determine the group specific epitopes of these CTL.
Results. Group specific CTL response against variant HIV-1 envelope proteins have been detected in unfractionated PBMC and cloned T cell populations. In unfractionated PBMC, cytotoxic responses were detected predominantly against one conserved env region (a.a. 228 287) in some of the individuals where others demonstrated a more heterogeneous response. Cloned CTL have been similarly detected against these domains. Studies are in progress using peptides to define the specific epitopes recognized by these CTL.
Conclusions. We have begun the task of defining the group specific epitopes recognized by HIV-specific CTL to several HIV proteins. These studies will help in efforts to develop a vaccine for HIV as well as in therapeutic attempts at adoptive immunotherapy.

W.C.O.43

LONG TERM CULTURE AND FINE ANTIGEN SPECIFICITY OF HIV-1 REVERSE TRANSCRIPTASE-SPECIFIC CYTOTOXIC T LYMPHOCYTE (CTL) CLONES

Walker Bruce D*; Birch-Limberger K*; Fisher L*; Young K**; Moss B***; and Schooley RT*. *Harvard Medical School and Mass. Gen. Hosp., Boston, MA. **Whitehead Inst., MIT, Cambridge, MA, ***NIAID, NIH, Bethesda, MD, USA.

Objective. To determine the viral antigens recognized by HIV-1 specific CTL.
Methods. HIV-1 RT-specific T cell clones were derived by culturing peripheral blood mononuclear cells from seropositive subjects at limiting dilution in the presence of recombinant interleukin-2 and a CD3-specific monoclonal antibody. Antigens recognized by these clones were determined in each case by both a) lysis of autologous EBV-immortalized B cells infected with a panel of vaccinia-HIV-1 recombinant viruses expressing truncated portions of the RT protein, and b) lysis of autologous EBV-immortalized B cells incubated with synthetic 25 amino acid RT-peptides.
Results. A total of 6 HIV-1 RT-specific CTL clones derived from 2 seropositive subjects were studied. In one subject, 2 peptide-defined epitopes, restricted by the class I antigens A2 and Bw60, respectively, were identified. In a second subject, 2 different peptide-defined epitopes, restricted by the HLA class I antigens A11 and B8, respectively, were found. These CTL clones have now been maintained in continuous culture for up to 7 months without loss of virus-specific cytotoxic activity.
Conclusions. HIV-1 specific CTL clones can be maintained in long term culture without exposure to exogenous viral antigen. The epitopes recognized by these CTL are heterogeneous and dependent upon the HLA type of the host. This approach should facilitate further mapping of the immunogenic epitopes of HIV.

W.C.O.40

IN VITRO LYMPHOCYTE PROLIFERATIVE RESPONSES TO RECOMBINANT AND SYNTHETIC PEPTIDE ANTIGENS OF HIV-1.
Krowka, John*, Stites, D.*, Steimer, K.**, Duzgunes, N.* et al. *University of California, San Francisco, USA and the **Chiron Corporation, Emeryville, CA, USA.

Proliferative responses of lymphocytes from HIV antibody-negative (HIV-) and -positive (HIV+) individuals to recombinant and synthetic envelope or core proteins were evaluated to assess the roles of cell-mediated immunity in HIV infections. All HIV- and most HIV+ individuals' lymphocytes did not proliferate when cultured with recombinant HIV proteins or soluble synthetic HIV peptides. Even lymphocytes from many HIV+ asymptomatic individuals with normal numbers of CD4+ cells that proliferated in response to other recall antigens such as cytomegalovirus (CMV) failed to proliferate in response to any HIV antigens in the presence of interleukin 2 (IL2) which can augment proliferative responses. A few HIV+ individuals' lymphocytes proliferated weakly when cultured with HIV antigens but these responses were generally transient in nature. These results indicate that the inability to generate or maintain vigorous helper T cell responses to HIV antigens may be important in allowing the progression of HIV-related diseases. In the presence of IL2, lymphocytes from many HIV+ individuals proliferated when cultured with liposome conjugates of a synthetic HIV envelope peptide ($ENVP_{466}$) but not when cultured with unconjugated liposomes or with liposomes conjugated to a peptide, $ENVP_{497}$, that constitutes the carboxy terminus of gp120. These studies as well as results from other laboratories indicate that the conjugation of synthetic peptides to liposomes may be useful to enhance their antigenicity or immunogenicity.

W.C.O.42

A CYTOTOXIC T LYMPHOCYTE INHIBITS AIDS VIRUS REPLICATION IN PERIPHERAL BLOOD LYMPHOCYTES.
Tsubota, Hiroshi; Lord, C.I. and Letvin, N.L. Harvard Medical School, New England Regional Primate Research Center, Southborough, Massachusetts, USA.

Objective. To characterise the CD8+ (suppressor/cytotoxic) lymphocytes which inhibit replication of HIV and SIV in PBLs.
Methods. PBLs of HIV-infected humans and SIV-infected rhesus monkeys were lectin-activated and maintained in IL-2 containing medium with RT activity assessed in culture supernatants.
Results. In a prospective study of SIV-infected monkeys, we demonstrate that this virus-inhibitory CD8+ cell is not present in PBLs in the first weeks following infection. Thus, the inhibitory lymphocyte population appears to undergo clonal expansion in the host during the course of infection. We also show that the rhesus monkey CD8+ lymphocyte inhibits SIV replication in autologous but not in major histocompatibility complex class I mismatched PBLs. These findings suggest that the virus-inhibitory cells have characteristics of antigen-specific T lymphocytes. The CD8+ cells which inhibit HIV and SIV replication were further defined on the basis of their phenotype. The inhibitory lymphocytes express the integrin family molecule 4B4 and the cytotoxic T lymphocyte-associated S6F1 epitope of LFA-1. Finally, this inhibitory function is blocked by anti-LFA-1 and anti-CD8 monoclonal antibodies, indicating that physical contact is required for the CD8+ lymphocyte-mediated inhibition of AIDS virus replication.
Conclusion. The cell which inhibits AIDS virus replication in PBLs of infected individuals is a cytotoxic T lymphocyte.

W.C.O.44

ANALYSIS OF THE STRUCTURAL AND NON STRUCTURAL PROTEINS OF HIV-1 RECOGNIZED BY PRIMARY CYTOTOXIC T LYMPHOCYTES
F. Tanneau[1], P. Sansonetti[1], M.P. Kieny[3], O. Lopez[2], L. Montagnier[1], Y. Rivière[1]. [1] Institut Pasteur, [2] CTS Pitié-Salpêtrière, [3] Transgène Strasbourg France.
Objective to further characterise HIV-1 specific cytotoxic effector cells in the peripheral blood of HIV-1 seropositive individuals.
Methods autologous EBV transformed lymphoblastoid cells were infected with recombinant vaccinia viruses expressing gag (p55, p18 or p25), pol., vif, nef or rev and used as targets of the cytotoxic activity present in PBMC of HIV seropositive donors.
Results a majority of HIV-1 seropositive donors have primary CD8+ CTL that lyse gag and polymerase expressing targets.
- Expression of the gag products p18 and p25 in addition to the precursor p55 is sufficient for recognition by CTL present in PBMC.
- Some donors contain primary CTL that recognise the HIV-1 regulatory proteins rev and nef (the phenotype of these CTL is CD8+).
- The gag specific CTL activity is stable in individual donors tested repeatedly for up to 18 months.
Conclusion Not only the viral structural proteins encoded gag and pol. but some of the nonstructural regulatory proteins of HIV-1 are recognized by CTL during HIV infection. Gag-specific cytotoxicity is maintained at similar levels over time in healthy HIV seropositive individuals. CTL recognition of these viral proteins may be important in the control of HIV infection in vivo.

W.C.0.45 NEUROPATHOLOGICAL STUDY OF SIV-INFECTED MACAQUES

Anderson, Daniel C.*, McClure, H.M.*, Ribas J.L.**, Ansari, A.*, Fultz, P.*, and Mirra, S.***
*Yerkes Regional Primate Research Center and Department of Pathology, Emory University, Atlanta, GA, **Armed Forces Institute of Pathology and Walter Reed Army Institute of Research, Washington, D.C., and ***VA Medical Center, Atlanta, GA, U.S.A.

Objective. To determine the pathologic changes in the CNS of macaque monkeys acutely or chronically infected with SIV isolates PBj-14 or SMM-9.
Methods. Brains and spinal cords from macaque monkeys were examined histologically at varied intervals post-SIV infection. Included were brains from 17 macaques that died 8-18 days post-infection (P.I.), brains from 2 animals that died at 7 and 9 months P.I., and brains from 7 chronically infected macaques that died 14-43 months P.I.
Results. Lesions were found in the brain as early as 8 days P.I. Changes seen in animals dying shortly after infection include (1) choroid plexitis with mononuclear cell and occasional multinucleated giant cell inflammation and necrosis of choroid plexus epithelial cells, and (2) meningitis with predominantly mononuclear cell inflammation. Parenchymal lesions were rare in animals dying acutely, but chronically infected animals showed a less striking choroid plexitis and more frequent parenchymal granulomatous lesions.
Conclusion. SIV infection in macaques produces CNS lesions with features comparable to HIV infection in man (meningoencephalitis with multinucleated giant cells and macrophages). Continued study of the pathogenesis of SIV infection should provide important information related to the pathogenesis of CNS involvement in AIDS. (Supported by NIH grant RR00165).

W.C.0.46 CLINICAL, IMMUNOLOGICAL, AND VIROLOGICAL FOLLOW UP OF HIV2 INFECTED RHESUS MONKEYS.

Dormont, Dominique (1,2); Livartowski, J. (1); Chamaret, S. (2), Guétard, D. (2); Rouzix , F. (1); Métivier, H. (3); and Montagnier, L. (2).
(1) Centre de Recherches du Service de Santé des Armées, Commissariat à l'Energie Atomique, Fontenay aux Roses , FRANCE. (2) Institut Pasteur, Paris, FRANCE (3) CEA, Bruyères le Châtel, FRANCE.

Objectives : To establish an animal model of human HIV infection and/or clinical manifestations of AIDS, in order to understand pathogenesis of HIV infection, to test therapeutic protocols, and vaccine strategies.
Methods: 10 rhesus monkeys have been inoculated with 2 different strains of HIV2 (ROD, EHO) "wild" or before being "adapted" in vitro to monkeys cells (baboons, cynomolgus, rhesus). Monkeys were injected both by IV route and intracerebrally. Follow-up consisted in clinical survey, serological tests (RIPA), monthly lymphocytes cultures, CD4+/CD8+ cells count and conventional blood chemistry tests. HIV2 isolated in vivo from monkeys PBL and CSF have been compared to starting viral matériel by restriction map and biological properties in cell cultures. A second "in vivo" passage of HIV2 strain which exhibited in vivo pathogenic effect is now performed.
Résults: 7 animals seroconverted (D13 - 230), earlier with the HIV2-ROD strain adapted on cynomolgus cells than the other strains. HIV2 was detectable in lymphocytes culture supernatants in 6 of the 7 animals who seroconverted and in 1 who remains seronegative. Significant lymphopenia and decrease of CD4+ cells count were observed in 6 animals. Two animals exhibited clinical symptoms which might be related to HIV2 infection: severe cachexia, dyspnea, neurologic symptoms related to actinomycetes typical lesions of the lungs and of the meninges, for one animal, and weight loss, lymphadenopathies, and pancytopenia for the other one. HIV2 isolated from these monkeys behave differently in cell culture than the starting viruses.
Conclusion: HIV2 is able to replicate in rhesus monkeys, and may induce clinical symptoms in some animals. This model has to be reproductible before being considered as a model for AIDS or for HIV infection. Molecular and biological markers of in vivo adaptation have to be investigated, and may help in understanding HIV infection pathogenesis and variability of clinical manifestations.

W.C.0.47 MONKEYS WITH SIMIAN AIDS PRODUCE AN ANTIBODY DIRECTED AGAINST A HISTONE-LIKE PROTEIN ON $CD4^+$ T-CELLS.

Stricker, Raphael B.*; Fultz, P.N.**; Haislip, A.M.*
*University of California, San Francisco, CA; **Yerkes Regional Primate Research Center, Emory University, Atlanta, GA, U.S.A.

Previously it was shown that patients with AIDS and AIDS-related conditions produce a cytotoxic autoantibody that binds to lectin-stimulated or virally-infected $CD4^+$ T-cells (Nature 327: 710-713, 1987). Subsequently it was discovered that the target antigen resembles a histone protein, H2B. We have now investigated the production of this antibody in monkeys infected with simian immunodeficiency virus (SIV). When macaque monkeys are infected with SIV, these monkeys develop symptoms of immunosuppression that are characteristic of simian AIDS (SAIDS). In contrast, when mangabeys are infected with SIV, they remain healthy. Sera from 10 mangabeys and 10 macaques infected with SIV were tested for the presence of antibody against histone H2B by immunoblotting. The ten mangabeys (all healthy) did not have antibody against histone H2B detected in their sera. Four of the macaques were healthy at the time of testing, and none of their sera contained antibody against the histone protein. In contrast, the other six macaques had symptoms of SAIDS, and all six had antibody against histone H2B. When sera from these animals were tested sequentially, detection of antibody against the histone protein appeared to coincide with the onset of disease. The histone-like antigen was also detected on macaque lymphocytes, as determined by immunoblotting using monoclonal antibody against histone H2B. We conclude that monkeys with SAIDS produce an antibody that reacts with a histone-like protein expressed on CD4+ T-cells. This antibody may play a key role in the destruction of CD4+ T-cells in both AIDS and SAIDS.

W.C.0.48 VACCINE PROTECTION AGAINST SIMIAN IMMUNODEFICIENCY VIRUS INFECTION

Daniel, Muthiah D., Sehgal, P., Wyand, M., Ringler, D., King, N., and Desrosiers, R.
New England Regional Primate Research Center, Harvard Medical School, Southborough, MA USA

Objective. To test the efficacy of inactivated simian immunodeficiency virus (SIVmac) as a vaccine.
Methods. Rhesus macaques were immunized by multiple inoculations with purified, disrupted, non-infectious SIV in adjuvant (threonyl muramyl dipeptide adjuvant formulation of Syntex).
Results. Immunized monkeys developed anti-SIV antibodies detectable by whole virus ELISA and by Western blot; these antibodies had weak neutralizing activity. These macaques were challenged with 200 to 1000 animal infectious doses of live, cell-free SIV one week after the last immunization. SIV recovery from peripheral blood and anamnestic antibody responses were used to monitor infection. Two of six vaccinated macaques showed no evidence of infection after challenge with live virus. One of four vaccinated macaques that became infected after challenge had a delayed anamnestic antibody response that appeared 24 to 40 weeks after challenge. Four of four unvaccinated macaques became infected with these doses and three have died with AIDS 118-258 days after challenge. Only one of six vaccinated-challenged macaques has died to date.
Conclusion. These results suggest that inactivated whole virus vaccination can protect macaques against SIV challenge. The SIV animal model appears useful for comparison of AIDS vaccine strategies.

W.C.0.49 EVIDENCE FOR PROGRESSION TO DISEASE IN CHIMPANZEES CHRONICALLY INFECTED WITH HIV-1?

Fultz, Patricia*; Siegel, R.*; McClure, H.*; Steimer,K.**; Dina, D.**; Swenson, B.*; Anderson, D.* et al.
*Yerkes Primate Research Center and Department of Pathology, Emory University, Atlanta, GA, USA; **Chiron Corporation, Emeryville, CA., USA

Objective: To assess the virologic, immunologic and clinical status of chimpanzees after long-term infection and immunization with HIV-1.
Methods: Following inoculation of HIV-1 and later therapeutic immunization with purified HIV antigens, chimpanzees were evaluated for hematologic status; virus status, including cell-free and cell-associated HIV and p24 antigenemia; and immune responses, including antibodies that neutralized virus infectivity, inhibited cell-to-cell transmission, syncytia formation, or RT activity.
Results: Of six chimpanzees infected for 45 to 58 months, three developed changes in antibody profiles or abnormalities in hematologic parameters. Two animals, one of which was persistently hypergammaglobulinemic for more than 4 years, lost antibodies to *gag*-encoded antigens. The third animal has been lymphopenic, with loss of $CD4^+$ cells, and thrombocytopenic for more than 1 year, and recently became viremic, as evidenced by isolation of cell-free HIV from plasma. Therapeutic immunization had little effect on HIV-specific immune responses or clinical status.
Conclusion: Long-term HIV-infected chimpanzees are developing abnormalities analogous to those that are predictive of AIDS in HIV-infected persons. If HIV-induced disease in chimpanzees is a function of length of time of infection, then HIV-infected chimpanzees may yet develop AIDS. (NIH grant RR-00165 and CDC Contract 200-88-0607).

W.C.0.50 GENETIC VARIATION OF SIV IN EXPERIMENTALLY INFECTED MACAQUES: TISSUE VERSUS TISSUE CULTURE

Johnson, Philip R.*, Olmsted, R.A.*, Purcell, R.H.**, and Hirsch, V.M.*
*Georgetown University, Rockville, Md.; ** NIAID/NIH, Bethesda, Md. U.S.A.

Objective. Lentiviruses have the potential for significant genetic variation during natural infection. Viruses isolated from infected animals in tissue culture may not represent the entire spectrum of genetic variation due to: i) selective growth of certain variants in tissue culture; and, ii) the presence of replication defective proviruses. To address these issues, we have begun to analyze and compare SIV proviral DNAs in tissues from SIV-infected macaques and in cell lines established from tissue culture isolates.
Methods/Results. Three groups of macaques were infected with SIV from a sooty mangabey (SIVsmm): group A received uncloned SIVsmm; group B received SIVsmm (smH-3), derived from a biologically active molecular clone; and, group C received smH-4, derived from a second SIVsmm molecular clone. One macaque in group A died 7 weeks after inoculation (from disseminated CMV infection). On Southern blot analysis, the original inoculum of SIVsmm contained one detectable proviral form. Portions of splenic tissue were either co-cultured with CEM cells or processed for genomic DNA isolation. Comparative Southern blotting revealed that: i) multiple proviruses were present in the acutely infected CEM cell line and the splenic tissue; and, ii) a major proviral form present in the splenic tissue (equimolar with the original form) was not detected in the CEM cell line. Furthermore, this proviral form was also detected (at varying levels) in liver, kidney, and lymph node. Cloning and molecular characterization of these proviral variants are underway.
Conclusions. Multiple proviral forms of SIV emerge during infection of macaques. Certain variants may not be recovered in tissue culture despite a high integrated proviral copy number in tissues. The importance of these variants is unclear, but they may play a role in the pathogenesis of SIV infection.

Basic Immunology (Part 3)

Th.C.0.1 SELECTIVE SIGNALING DEFECT VIA THE CD3/TCR COMPLEX IN T CELLS FROM HIV-INFECTED MEN.

R.A. Gruters, C.J.M. van Noesel, F.G. Terpstra, P.Th.A. Schellekens, R.A.W. van Lier, F. Miedema, Central Lab. Netherlands Red Cross Blood Transfusion Service and the Lab. of Exp. and Clin. Immunology of the University of Amsterdam, Amsterdam, The Netherlands.

We have previously shown that HIV infection induces qualitative T-cell defects before the onset of CD4+ T-cell depletion. In this study the responses of T cells from HIV infected persons to different proliferative signals were investigated using monoclonal antibodies (mAb) against T-cell membrane antigens. Due to intrinsic defects, T cells from asymptomatic HIV-infected men responded poorly to activation signals via the CD3/T-cell Receptor ((TCR) complex and CD2 that are mediated by intracellular signalling routes dependent on PK-C. In contrast, T-cell proliferation induced via the alternative CD28 activation pathway was unaffected. Since, Ca^{2+} mobilisation and PK-C activation were normal, the defect in CD3/TCR triggering lies distal from PK-C activation. In a longitudinal study, it appeared that the anti-CD3 mAb responsiveness dramatically declined 12-15 months before onset of ARC/AIDS, whereas the anti-CD28 response remained relatively normal. The generation of cytotoxic T cells (CTL) in an anti-CD3 driven system was also impaired and could be restored by addition of rIL-2 and anti-CD28. An early effect of HIV infection on T-cell reactivity may disturb the balance between virus and host defense which may be a rationale for treatment of asymptomatic HIV-infected individuals with immune modifiers.

Th.C.0.3 HUMAN MONOCLONAL ANTIBODIES TO VARIANT AND CONSERVED EPITOPES OF HIV ENVELOPE GLYCOPROTEINS.

Robinson, James, Holton, D., Pacheco, S., Liu, J., and McMurdo, H. Louisiana State University Medical School, New Orleans, LA, U.S.A.

Hypervariable regions of HIV env genes appear to encode potential antigenic sites but the extent that variant envelope antigens are immunogenic in HIV infected patients has not been fully delineated. To investigate this question, we proposed to use Epstein-Barr virus (EBV) transformation of B cells from HIV infected subjects to generate human monoclonal antibodies (HMab) that might identify variant or conserved envelope antigens that immunised each patient. From two asymptomatic patients, we have produced 2 IgG HMabs that bind to gp120/160 of HIV. Both HMabs were tested by Western blot and ELISA for reactivity with gp120/160 of 9 different strains of HIV. One HMab, designated K24-3b, reacted with gp120 of 6 strains, did not react at all with gp120 of 2 strains, and showed significantly diminished reactivity with 1 strain. The other HMab, designated N70-2.3a, reacted with gp120/160 of all 9 strains. These results indicate that K24-3b recognizes a variant epitope while N70-2.3a binds to a conserved epitope. K24-3b does not appear to have neutralizing activity but has been tested against only 1 of the 9 strains; N70-2.3a has not been tested for neutralization. From the B cell donor of N70-2.3a, we also produced 3 other IgG HMabs that bind to gp120/160 but these antibodies have not been further characterized. These results demonstrate that it is possible to generate HMabs to HIV glycoproteins which will allow studies of the extent and importance of antigenic variation in HIV.

Th.C.0.5 DETECTION OF ANTI-CD4 AUTOANTIBODIES IN THE SERA OF HIV INFECTED PATIENTS USING RECOMBINANT SOLUBLE CD4 MOLECULES.

Chams, Vida* ; Jouault, T* ; Fenouillet, E* ; Gluckman, J.C.* ; Klatzmann, D*
* Laboratoire de Biologie et Génétique des Déficits Immunitaires, Groupe Hospitalier Pitié-Salpêtrière, Paris, FRANCE.

The use of purified recombinant soluble CD4 (sT4) allowed the detection of high titers of anti-CD4 immunoglobulins in the sera of 3 out of 33 HIV-infected patients. Binding of these antibodies to sT4 was first detected by enzyme-linked immunosorbent assay (ELISA), and their reactivity was blocked in a dose-dependent manner by preincubation with sT4. The antibodies could also immunoprecipitate iodinated sT4, but even specific anti-CD4 antibodies purified on Sepharose CL4B-CNBr beads coupled to sT4 molecule, failed to recognize CD4 expressed on the surface of CD4+ lymphocytes or cell lines. A truncated soluble CD4 molecule containing only the first two amino-terminal domains of the CD4 molecule, as antigen, did not react with these sera in ELISA, nor did it block antibody binding to sT4. Both these human sera and Leu3a, a mouse monoclonal antibody (mAb) which recognizes an epitope of CD4 close to the HIV binding site, failed to compete with one another for binding to sT4. Because these antibodies did not recognize epitope(s) of the CD4 molecule close to the HIV binding site, they are not likely to be anti-idiotypic antibodies directed against anti-HIV envelope antibodies. The exact location of the recognized epitope(s), as well as the role, if any, of these antibodies in the pathophysiology of HIV infection is presently investigated.

Th.C.0.2 CHEMICALLY INDUCED CD4 MUTANTS PROVIDE EVIDENCE FOR ADDITIONAL SITES INVOLVED IN HIV-1 INFECTION AND SYNCTIA

Hillman, K.*; Manischewitz, J.*; Seeman, R.*; Hooley, J.**;
Hana Golding* *LDV, DV, CBER, FDA and **NIAID, Bethesda, MD, U.S.A.

Objective. To identify new sites on the CD4 receptor which are involved in HIV-1 infection and syncytia formation.
Methods. CEM T cells were treated with the mutagen EMS, followed by negative selection with OKT4A + C' and positive selection of $OKT4^+$ mutants by FACS sorting. Mutants were analysed by staining with anti-CD4 reagents and tested for their ability to be infected with HIV-1 and to form syncytia following infection with gp160-vaccinia recombinant virus.
Results. Several groups of interesting mutants were isolated and cloned: (a) CD4-LOW mutants (5-10% of wild type expression) which nevertheless were susceptible to HIV-1 infection, and formed normal number of syncytia 24 hr after gp160-vaccinia infection (inhibitable by OKT4A and Leu3A mAb). (b) CD4-MED mutants (20-40% of wild type expression). Most of them behaved like wild type CEM in all functional assays. Four mutants in this group, while expressing CD4-epitopes required for HIV-1 binding (OKT4A, Leu3a, MT151), were neither infected by HIV-1, nor formed syncytia after gp160-vaccinia infection. The expression of other surface markers were like wild type CEM.
Conclusions. (a) HIV-1 infection of T cells and gp160-mediated syncytia formation are highly efficient processes requiring few CD4 receptors. (b) In addition to the previously identified gp120 binding sites on the CD4 receptor molecules, there are other regions on CD4 (or on a closely associated surface molecule) which are involved in HIV-1 syncytia formation. Biochemical and molecular approaches are currently being used in the further analyses of these CD4 mutants.

Th.C.0.4 A HYBRIDOMA PRODUCING HUMAN MONOCLONAL IgG NEUTRALIZES THE HTLVIIIb ISOLATE IN VITRO.

Kawamura, T.***; Lake, D.*; Robinson, E.**; Petersen, E.*; Mitchell, W.**; and Hersh, E.*.
*Department of Hematology/Oncology, University of Arizona, Tucson, Arizona, 85724, USA, **Department of Pathology, Vanderbilt University, Nashville, Tennessee, 37232, USA, ***Teijin Institute for Biomedical Research, Tokyo, Japan.

Objective. To evaluate human monoclonal antibodies (HuMAb) for their ability to neutralize HIV-1 in vitro.
Methods. HuMAb were generated by fusion of the mouse myeloma cell line P3x63AgU1 with splenic lymphocytes from an HIV seropositive patient. Protein-A purified HuMAb were assayed for neutralizing activity with and without the presence of complement in an MT-2 cell survival assay and by a non-commercial p24 antigen capture assay.
Results. An IgG1, lambda-chain, HuMAb, designated S1-1, demonstrated neutralizing activity against the HTLVIIIb isolate. This HuMAb did not react with HTLVIIIb antigens in western blotting, but did react with the surface of HTLVIIIb infected cells. Neutralization of HTLVIIIb by S1-1 was observed from 60 ug/ml to 7.5 ug/ml in the presence and absence of complement. S1-1 neither enhanced infection nor did it inhibit syncytium formation. HuMAb S1-1, however, could not neutralize the HTLVIIIRF isolate.
Conclusion. We report the generation of a HuMAb, S1-1, that neutralizes HIV, does not enhance infection, and does not inhibit syncytium formation.

Th.C.0.6 ANTIBODY RESPONSE TO THE HIV-1 REGULATORY GENE PRODUCTS NEF, VIF AND VPR IN HIV-1-INFECTED SERONEGATIVE INDIVIDUALS

Jean Claude AMEISEN*, B. GUY**, M. LOCHE***, S. CHAMARET****, Y. MOUTON*****, A. CAPRON* et al.
*Institut Pasteur, Lille; **Transgene SA, Strasbourg; ***Université de Genève, Genève, Switzerland; ****Institut Pasteur, Paris, France; *****CHU Tourcoing, France.

Objective. To investigate whether HIV regulatory gene products might be expressed in vivo and induce a specific immune response during the serologically silent period that follows infection by the human immunodeficiency virus (HIV-1).
Methods. Seventeen HIV-1-seronegative (ELISA, Western blot), -p24/25 seric-, -viral antigen-negative individuals at risk for HIV infection were studied. Antibodies to *nef* (involved in maintenance of proviral latency), *vif* (involved in maturation of virion infectivity), and *vpr* (o unknown function), were searched by radioimmunoassay and/or Western blot using *nef* recombinant protein (95% pure); 8 synthetic *nef* peptides; 3 synthetic *vif* peptides; 2 synthetic *vpr* peptides. HIV-1 proviral DNA (gag gene) was searched by oligonucleotide hybridization, following enzymatic amplification of HIV DNA in peripheral blood mononuclear cells.
Results. Antibodies to HIV regulatory gene products were detected in 12/17 at risk individuals. This antibody response was correlated in 11 individuals with the detection of HIV-1 proviral DNA. Such latent HIV infections have now been followed for 10 and 6 months in 5 individuals. In addition, a retrospective and prospective study of HIV-1-seropositive individuals has shown 1) antibodies to *nef* 4 months before HIV-seroconversion (in 1/12 individual); 2) the persistence of antibodies to *nef* and of HIV-1 proviral DNA in a case of spontaneous complete HIV-1-seronegativation.
Conclusion. These findings suggest that HIV regulatory genes products can in some cases be expressed prior to the initiation of detectable HIV virion synthesis. They represent a basis for new diagnostic tests and could be applicable in the design of alternative vaccine strategies.

Aspects pathologiques de l'infection par le VIH
Pathological Aspects of HIV Infection

Th.C.O.7

DISTINCT HISTOLOGIC LYMPH NODE CHANGES FOLLOWING HIV INFECTION IN ADULTS

Harris, Nancy L. Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114, U.S.A.

Objective. To develop a clinically relevant classification of lymph node histopathology in HIV infection

Methods. This report is a review of histopathologic and immunohistologic findings in lymph node biopsy and autopsy specimens from patients with HIV infection seen at Massachusetts General Hospital since 1982, as well as a review of the recent literature.

Results. At least 6 major types of lymph node histopathology are seen in HIV infected patients, either alone or in combination with other types:

1. Florid reactive follicular hyperplasia ± follicle-lysis
2. Follicular involution
3. Diffuse pattern (± lymphocyte depletion ± angioimmunoblastic changes.)
4. Angiofollicular hyperplasia (Castleman-like lesion)
5. Tumors: a. Malignant lymphoma (Burkitt-like or immunoblastic)
    b. Kaposi's sarcoma (primary or secondary)
6. Specific infections

Types 3-6 are usually associated with one or more diagnostic criteria for AIDS, while types 1 and 2 may be associated with PG4ARC, and are not specific for HIV infection. Types 1 and 2 may be associated with normal lymph node CD4/CD8 populations or with CD4 depletion; CD4 depletion is often pronounced in type 3. Type 4 pattern is strongly correlated with lymphadenopathic Kaposi's sarcoma.

Conclusion. Lymph nodes in HIV infected patients may show a variety of patterns with important prognostic implications.

Th.C.O.9

IN SITU HYBRIDIZATION FOR DETECTION OF HIV GENOME

Peter Biberfeld*, Carlo Parravicini**, Marianne Ekman*, Anne Magnusson*, Anna Porwit*, Robert C. Gallo***, *Immunopathology Lab., Karolinska Institute, Stockholm, Sweden, **V Chair Pathology, Milano University, Milano, Italy, ***LTCB, NCI, NIH, Bethesda, Maryland, USA.

The pathogenic mechanisms of HIV have been studied by in situ hybridization and immunohistochemistry in lymph nodes of patients at various stages of HIV infection and brains of AIDS cases with encephalitis. For in situ hybridization use was made of ^{35}S labeled (P. Biberfeld, M. Harper et al., AJP, 125(3):436-442, 1986) as well as of alkaline phosphatase (HIV SNAP™ Probe Kit, DuPont) and Digoxigenin (Genius™ Non-radioactive DNA Labeling and Detection Kit, Boehringer Mannheim) labeled probes. By immunohistochemistry the presence of HIV gag and env antigens as well as various cell markers was studied. Our findings indicate significant differences in the local replication of HIV in CNS and lymph nodes. In both tissues association of histopathological changes, HIV-replication and antigen deposition with infiltration of CD8+ cells suggested a possible effector function of these cells. The non-radiolabeled probes were clearly advantageous for screening of biopsy material and cells and also enabled simultaneous detection of viral antigens and RNA.

Th.C.O.8

DETECTION OF HIV IN LYMPH NODES

Räcz, Paul. Bernhard-Nocht-Institute for Tropical Medicine, Hamburg, West Germany.

In lymph nodes (LN) of HIV-infected persons the causative agent can be detected using electron microscope (EM), immunohistochemistry (IH) or in situ hybridization. Applying immunostaining on frozen sections gag proteins of HIV can be visualized in germinal centers (GC) of LN. This reaction is highly sensitive and specific, therefore, it can be used for diagnostic purposes. Coincident staining with gag proteins and antibody to follicular dendritic cells (FDC) shows the association of viral proteins to FDC. In correlation with these findings, EM shows intact HIV-particles along the processes of FDC. Results of in situ hybridization have also shown the presence of cells expressing viral RNA inside the GC. HIV enters the GC early during the course of infection. We have demonstrated the infection of GC both with EM and IH 6 weeks after seroconversion. Once gained access to GC, HIV can persist here for long time periods. On repeated biopsy specimens we have detected HIV up to 2 year intervals. Not only GC of LN but also those in gut associated lymphoid tissue contain HIV-proteins associated with FDC. Thus, it is very likely that FDC as antigen trapping and retaining cells are very important in the pathogenesis of HIV-infection. FDC probably capture HIV transported by lymphatics. Using EM, IH and in situ hybridization we have found evidence for spreading of HIV via lymphatics. We feel that this way of dissemination is especially important when HIV enters the body through a mucous membrane.

Th.C.O.10

BIOLOGICAL FUNCTIONS OF HUMAN MONOCLONAL ANTIBODIES TO HIV.

Zolla-Pazner S*; Robinson, Jr., HE**; Vitetta ES+ and Weinhold K++. *NY Veterans Admin. Hosp., New York, NY, **Vanderbilt Univ., Nashville, TN, +Univ. of Texas Southwestern Med. Ctr., Dallas, TX & ++Duke Univ. Med. Ctr., Durham, NC.

OBJECTIVE: To characterize the biological functions of human monoclonal antibodies (mAb) to HIV.

METHODS: Mononuclear cells from peripheral blood of HIV-infected subjects were infected with Epstein-Barr virus and cultured in microtitre plates for one month. Wells making anti-HIV were expanded and cloned at limiting dilution. mAb from each clone were tested for specificity by ELISA, radioimmunoprecipitation, and Western blot and assayed for function as described in abstracts 2622, 4193 and 4475.

RESULTS: Of 11 lymphoblastoid lines producing mAb to HIV, mAb from 6 lines react with gp41; five react with p24. mAb to gp41 mediate antibody-dependent cellular cytotoxicity requiring 1-5 ug mAb/ml. Of the 11 mAb, only one, specific for gp41, mediates complement- and antibody-dependent enhancement of HIV infection requiring 1 ng mAb/ml. Two mAb to gp41 were coupled to the deglycosylated A chain of ricin. 50% killing of the HIV-infected T cell line, H9, occurs at 500 ng mAb/ml. 50% killing of the HIV-infected U937 monocyte cell line is achieved at 1000 ng/ml in the absence of chloroquine and at 10 ng/ml in the presence of chloroquine. None of the mAb to gp41 are neutralizing or mediate syncytium inhibition. None of the mAb to p24 are active in any of the described functional assays.

CONCLUSIONS: Human mAb to gp41 mediate a variety of biologic functions. No biological functions have, as yet, been ascribed to human mAb to p24.

RETROVIRAL VECTORS EXPRESSING SOLUBLE CD4: A POTENTIAL GENE THERAPY FOR AIDS

Morgan, Richard A.*; Looney, D.J.***; Muenchau, D.D.*; Wong-Staal, F.**; Gallo, R.C.** and Anderson, W.F.*
*Laboratory of Molecular Hematology, National Heart, Lung, and Blood Institute, and **Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD 20892, USA, ***Division of Retrovirology, Walter Reed Army Institute of Research, Rockville, MD 20850, USA.

Objective. Development of murine retroviral vectors which express a soluble form of the CD4 antigen and demonstration of the use of these vectors to inhibit HIV-1 infection in vitro.
Methods. A translation stop codon was introduced into the human CD4 gene at amino acid 202, and the now soluble form of CD4 (sCD4) introduced into the murine retroviral vector N2. sCD4 expression was monitored by immunoprecipitation and HIV-1 inhibition was scored by assaying for p24 production.
Results. Retroviral vectors have been developed which produce a secreted form of the helper/inducer T-cell antigen, CD4. Amphotropically packaged vectors were used to transduce cells (including several transformed cell lines as well as primary fibroblast and endothelial cells) and these cells were shown to express the secreted CD4 gene product. The sCD4 produced by the viral vectors is immunoprecipitated by monoclonal antibodies against CD4 which specifically block HIV infection of helper/inducer T-cells. A direct physical interaction of vector-produced sCD4 and HIV-1 gp120 was demonstrated by coprecipitation of sCD4/gp120 with antiserum directed against HIV gp120. Further, transduced cells producing sCD4 can protect HIV susceptible cells from infection by HIV.
Conclusion. We have demonstrated that retroviral vectors can be constructed which express sCD4 and that cells transduced by these vectors can protect cells from HIV infection in culture. sCD4 retroviral vectors could potentially be used to engineer the cells of an AIDS afflicted individual, and thus these data are a model for a potential gene therapy approach for the treatment of AIDS.

Th.C.O.13

INHIBITION OF THE INFECTIVITY OF HIV-1 AND HIV-2 BY SOLUBLE rCD4: DIFFERENTIAL SENSITIVITY TO SOLUBLE rCD4.

Hayashi, S*; Looney, DL**; Chamow, SM***; Wong-Staal, F**; Broder, S*; and Mitsuya, Hiroaki*. *The Clinical Oncology Program, **Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD; ***Genentech, Inc., South San Francisco, CA, USA.

Objects: We examined the antiviral activity of soluble recombinant CD4 protein (rCD4) against HIV-1 and HIV-2 in vitro. We also tested the binding characteristics of HIV-1 and HIV-2 and their binding inhibition by rCD4.
Methods: Viruses: HIV-1 (HTLV-III$_B$, RF-2, HXB2D) and HIV-2 (LAV-2 and HIV-2$_{BZ}$). The antiviral activity of soluble rCD4 against HIV-1 and HIV-2 was assessed in the cytopathic effect inhibition assay using susceptible CD4$^+$ ATH8 cells. Viruses were labelled with 5,6-^{3}H-uridine; binding and binding inhibition assays were performed in CD4$^+$ H9 and MOLT3 cells.
Results: Soluble rCD4, at 1 to 5 µg/ml, exerted a complete protection of ATH8 cells exposed to 2x10^4 TCID$_{50}$ dose of cell-free HIV-1 (ED$_{50}$ against HIV-1: 0.7-1 µg/ml), while ~200 µg/ml rCD4 was required to give an ED$_{50}$ when the cells were exposed to the same TCID$_{50}$ dose of cell-free HIV-2. Moreover, when the target ATH8 cells were cocultured with HIV-1 and HIV-2-producing cells, sensitivity of the viruses to the blocking by rCD4 was also found to be different. OKT4A antibody, however, exerted a virtually similar blocking effect to both HIV-1 and HIV-2 in the cytopathic effect inhibition assay. Viral binding study revealed that HIV-2 viruses were much less susceptible to the blocking by rCD4 than HIV-1 while OKT4A and dextran sulfate blocked the binding of both viruses in an identical fashion. These data suggest differences in the stability or the structure of envelope glycoproteins in HIV-1 and HIV-2, which may have a clinical relevance in the treatment of HIV infection.

[3]The Clinical Oncology Program, National Cancer Insitute, National Insitutes of Health, Bethesda, MD, 20892. [4]Division of Hematology-Oncology, Harvard Medical School, New England Deaconess Hospital, Boston, MA, U.S.A.

We have used parts of the sequence of CD4, the cellular receptor for HIV, to construct a novel type of antibody-like molecule, termed immunoadhesin. In these molecules the antigen-binding region (Fab) of antibody has been replaced by the gp120-binding domain of CD4. Our CD4 immunoadhesins bind gp120 and block HIV-1 infection of T cells and monocytes in a manner indistinguishable from soluble rCD4. They also possess some properties of antibodies, including long *in vivo* plasma half-life and high-affinity binding to Fc receptors. The improved plasma half-life should allow increased plasma levels, blocking virus more effectively than rCD4, and Fc receptor binding may recruit mechanisms for the elimination of virus and virally-infected cells. The antibody-like properties of these constructs, together with their theoretical capability to block all isolates of the virus, offer hope for an active defense against HIV-1.

Th.C.O.12

SPECIFIC ANTI-HIV ACTIVITIES OF A RECOMBINANT HUMAN CD4-PSEUDOMONAS EXOTOXIN HYBRID TOXIN

Berger, Edward A.*; Chaudhary, V.K.**; Clouse, K.A.***; FitzGerald, D.J.**; Pastan, I.**; and Moss, B.*.
*Laboratory of Viral Diseases, NIAID, and **Laboratory of Molecular Biology, NCI, NIH, Bethesda, MD, USA, ***Georgetown University, Washington, D.C., USA.

Objective. To characterize various anti-HIV properties of CD4(178)-PE40, a recombinant protein containing the gp120-binding region of human CD4 linked to active regions of Pseudomonas exotoxin A.
Methods and Results. Using cell viability assays, CD4(178)-PE40 was found to selectively kill a number of human T-cell lines chronically infected with HIV-1, with ID$_{50}$ values as low as 90 picomolar. When uninfected human T-cell lines were co-cultured with small fractions of HIV-1 infected cells, the infection spread throughout the culture within 13 days, as monitored by the production of RT and by the killing of most of the initially uninfected population. By both criteria, CD4(178)-PE40 nearly completely prevented the spread of infection for up to 17 days. Control assays with CD4 derivatives lacking the active toxic regions indicated that this protection was due largely to selective killing of the infected cells, rather than to a simple blocking effect by the CD4 moiety. CD4(178)-PE40 proved active against cells expressing vaccinia-encoded envelope glycoproteins from a variety of primate immunodeficiency viruses, including divergent strains of HIV-1 as well as SIV. The hybrid toxin displayed no cytotoxic activity against human B-cell and monocyte lines expressing high levels of MHC Class II antigens.
Conclusion. These findings support the potential value of CD4-Pseudomonas exotoxin hybrid proteins as novel AIDS therapeutic agents.

Th.C.O.14

THE DEVELOPMENT OF IMMUNOTOXINS SPECIFIC FOR HIV-INFECTED CELLS.

Till, Mark A.*; Ghetie, V.*; Gregory, T.**; Uhr, J.W.*; Capon, D.**; and Vitetta, E.S.*.
*University of Texas Southwestern Medical Center, Dallas, Texas
**Genentech, Inc., South San Francisco, California, U.S.A.

Objective. To determine if an immunotoxin (IT) composed of recombinant CD4 (rCD4) linked to deglycosylated ricin A chain (dgA) is capable of killing HIV-infected T cell (H9) and monocyte (U937) lines.
Methods. rCD4 was conjugated to dgA *via* a heterobifunctional cross-linker, N-succinimidyl-S-thioacetate (SATA). Ovalbumin (OVA) was also conjugated to dgA as a control. Each IT was cultured with HIV-infected or uninfected H9 or U937 cells for 36 hours and toxicity was assessed by pulsing cells with [^{3}H]-thymidine for 6 hours.
Results. The control IT (OVA-dgA) did not kill infected or uninfected H9 or U937 cells at concentrations less than 10^{-7} M. rCD4-dgA killed 50% of infected H9 cells at a concentration of 1 x 10^{-10} M (IC$_{50}$ = 1 x 10^{-10} M). rCD4-dgA was not toxic to uninfected H9 cells at concentrations less than 10^{-7} M. Similar results were obtained with infected U937 cells. rCD4-dgA killed infected U937 cells with an IC$_{50}$ of 1 x 10^{-9} M but was not toxic to uninfected U937 cells. Chloroquine markedly potentiated specific killing resulting in an IC$_{50}$ of 4 x 10^{-11} M. Specificity of killing was demonstrated by inhibiting the toxicity of rCD4-dgA by pre-incubation with rgp120, 50-fold excess free-rCD4 and monoclonal antibody to the gp120-binding site or CD4, but not by BSA or another anti-CD4 antibody directed to a different site on CD4 not involved in gp120 binding.
Conclusion. rCD4-dgA specifically kills HIV-infected lines of T cells and monocytes.

Th.C.O.16

EFFECT OF RECOMBINANT SOLUBLE CD4 IN RHESUS MONKEYS INFECTED WITH SIMIAN IMMUNODEFICIENCY VIRUS OF MACAQUES.

Letvin, Norman L.*; Watanabe, M.* ; Reimann, K.A.*; DeLong, P.A.*; Liu, T.** and Fisher, R.A.**. *Harvard Medical School, New England Regional Primate Research Center, Southborough, Massachusetts, USA, **Biogen Research Corporation, Cambridge, Massachusetts, USA.

Objective. To assess the therapeutic effect of recombinant soluble CD4 (rsCD4) in SIV$_{mac}$-infected rhesus monkeys.
Methods. Two normal and 4 SIV$_{mac}$-infected rhesus monkeys received 2 mg rsCD4, intramuscularly, daily for 30 days. One SIV$_{mac}$-infected monkey received a second 30 day course of treatment.
Results. Intramuscular administration of rsCD4 resulted in a peak plasma level of greater than 10% of the calculated maximum possible plasma rsCD4 level within 15 min and a plasma half life of 6 hrs. None was measurable in the CSF. The normal monkeys experienced no significant adverse reaction to the rsCD4. SIV$_{mac}$ was readily isolated from PBLs and bone marrow macrophages of the infected monkeys before starting treatment, but became difficult to isolate soon after treatment had begun. Moreover, the diminished in vitro growth of both granulocyte-macrophage and erythrocyte progenitor cell colonies from the bone marrow of these monkeys rose to normal levels during treatment. Although an anti-rsCD4 antibody response was generated in these monkeys, retreatment of an animal resulted in the same improvement in clinical parameters achieved during the first course of rsCD4.
Conclusion. rsCD4 may prove valuable in the treatment of humans infected with HIV.

Mise au point de médicaments : utilisation de l'AZT et d'autres oligonucléotides dans le traitement du SIDA
Drug Development: Use of AZT and Other Oligonucleotides in AIDS Therapy

Th.C.0.17

Differential modulation of HIV replication and AZT activity in monocyte/macrophages by GM-CSF, M-CSF, and G-CSF.

Perno, Carlo-Federico, Yarchoan, R., Cooney, D.A., Mitsuya, H., Johns, D.G., and Broder, S. National Cancer Institute, Bethesda, MD, USA.

Objective. To study the ability of granulocyte-macrophage colony stimulating factor (GM-CSF), macrophage-colony stimulating factor (M-CSF) and granulocyte-colony stimulating factor (G-CSF) to modulate HIV replication and/or the antiviral activity of AZT in monocyte/macrophages (M/M).
Methods. Elutriated M/M were exposed to 100 U/ml GM-CSF, 1,000 U/ml M-CSF, or 500 U/ml G-CSF for 5 days before challenge with HIV-1 (monocytotropic strain HTLV-III_{Ba-L} or lymphotropic strain HTLV-III_B) with/without AZT.
Anabolic phosphorylation of AZT was also studied in M/M with/without GM-CSF.
Results. GM-CSF enhances replication (up to 1,000%) of both HTLV-III_{Ba-L} and HTLV-III_B in M/M, and reduces >100% the minimum viral dose required to productively infect the M/M. M-CSF also enhances HIV replication (but less than GM-CSF), while G-CSF had no such effect. Despite increasing HIV infection, GM-CSF activates the antiviral activity of AZT and related thymidine and uridine congeners in M/M: 0.01 uM AZT induces >90% viral inhibition in GM-CSF-stimulated M/M, while 1 uM AZT is required to achieve the same effect in M/M without GM-CSF. The activity of other dideoxynucleosides not related to AZT is not enhanced by GM-CSF. Neither M-CSF nor G-CSF modulated AZT activity in M/M. GM-CSF increases the intracellular level of AZT and its triphosphorylated form in M/M, but only induced a minimal increase of thymidine-5'-triphosphate (dTTP). Thus the ratio of AZTTP/dTTP is substantially increased in M/M exposed to GM-CSF, and this may explain its enhancement of AZT activity.
Conclusion. A combination of GM-CSF plus AZT (or a related congener) may be worth exploring in patients with HIV-related disease.

Th.C.0.18

INHIBITION OF HIV REPLICATION BY NOVEL PHOSPHOLIPID DERIVATIVES OF AZT AND OTHER ANTIRETROVIRAL NUCLEOSIDES IN VITRO

Hostetler, Karl Y.*,** and Richman, Douglas D.**
*Vical Inc., San Diego, California and **University of California, San Diego and the VA Medical Center, San Diego, California, 92161, USA

Monocyte/macrophages represent an important reservoir of HIV infection. Specific therapies to target these cells might treat HIV infection more effectively. Consequently, we synthesized phosphatidylAZT (pAZT) and AZT diphosphate diglyceride (AZTddg), new phospholipids having 5'-phosphorylated AZT as their polar head groups. Liposomal pAZT and AZTddg (Prosomes) were incubated with CEM cells infected with HIV-1. The amount of drug required to reduce by 50% the release of p24 antigen into the culture medium after three days was determined (ID_{50}). The ID_{50} values for pAZT and AZTddg were 1.3-2 and 7 uM, respectively. No cell toxicity was observed at liponucleotide concentrations of 100 to 200 uM or greater. Liposomes with no liponucleotide were ineffective. pAZT was also effective in mutant CEM cells lacking thymidine kinase (tk), demonstrating that the new AZT compound can be metabolized directly to AZT-monophosphate. AZT has no antiviral effect in these cells. Phospholipid derivatives of AZT, ddT and ddC were also effective in a plaque inhibition assay in CD4-HeLa cells and in p24 reduction assays both in U937 cells and primary human macrophages. In conclusion, phospholipids containing AZT and other dideoxynucleosides have been synthesized and shown to be effective in reducing HIV p24 production and plaque formation. These compounds are relatively non-toxic, bypass phosphorylation by cellular tk and appear to be promising candidate compounds for treatment of the monocyte/ macrophage reservoir of HIV infection.

Th.C.0.19

INHIBITION OF HIV EXPRESSION: ENHANCEMENT OF ACTIVITY OF PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES BY CHEMICAL MODIFICATION.

Matsukura Makoto*, Mori K.**, Zon G.***, Cohen J.S.** and Broder S.*, *Clinical Oncology Program, **Medicine Branch, National Cancer Institute, National Institutes of Health, Bethesda MD and *** Applied Biosystems Inc., Foster City CA, U.S.A.

Objective. Phosphorothioate oligodeoxynucleotides in an antisense configuration against the HIV rev mRNA showed significant inhibition against HIV-1 viral expression in chronically infected cells (Proc. Natl. Acad. Sci. 1989, in press). However, relatively high concentrations were required to inhibit viral expression. Therefore, it is reasonable to explore chemical modifications of the phosphorothioate oligomer to enhance such anti-HIV activity.
Methods. We synthesized a series of compounds by linking intercalating moieties or by modifying the bases. Compounds were tested in the viral expression inhibition assay using chronically HIV-1 infected H9 cells.
Results. Anthracycline-conjugated and acridine-conjugated antisense phosphorothioate oligomers against rev showed more potent inhibitory activities against the viral expression in chronically infected cells in comparison to unmodified phosphorothioate antisense by approximately 10 fold and 5 fold, respectively. Another modification, the use of alkyl-amino derivatives on thymidine bases, also showed an enhancement of the antiviral activity by approximately 5 fold. Therapeutic indices in these modified phosphorothioate oligomers are at least comparable to that in the unmodified antisense phosphorothioate oligomer.
Conclusion. Certain modifications of antisense phosphorothioate oligomers could result in advantages to potential therapeutic intervention against AIDS and related disorders.

Th.C.0.20

5-HALOGENO-3'-FLUORO-2',3'-DIDEOXYURIDINES ARE POTENT INHIBITORS OF RETROVIRUS REPLICATION *IN VITRO*

Jan Balzarini, A. Van Aerschot, C. Roelants*, R. Pauwels, M. Baba, D. Schols, P. Herdewijn and E. De Clercq.
Rega Institute for Medical Research and *Laboratory of Hematology, K.U.Leuven, B-3000 Leuven, Belgium

The 5-halogeno (i.e. 5-fluoro-, 5-chloro-, 5-bromo- and 5-iodo) derivatives of 3'-fluoro-2',3'-dideoxyuridine (FddUrd), designated FddFUrd, FddClUrd, FddBrUrd and FddIUrd, respectively, were synthesized and evaluated for their activity against human immunodeficiency virus (HIV) and simian AIDS related virus (SRV). FddFUrd did not shown any appreciable antiretrovirus activity at subtoxic concentrations. In contrast, all three other 5-halogeno FddUrd derivatives inhibited HIV-1 and HIV-2 replication in MT-4 cells at an effective dose (ED_{50}) of about 0.2-0.7 µM. Also, HIV-1-induced antigen expression in HUT-78 cells was suppressed by the three 5-halogeno FddUrd derivatives. FddClUrd was markedly more selective in its anti-HIV activity in MT-4 cells than FddBrUrd and FddIUrd. Its selectivity index was similar to that of 3'-azido-2',3'-dideoxythymidine (AZT, retrovir). FddClUrd was also effective in inhibiting SRV-induced giant cell formation in Raji cell cultures (ED_{50} : 4 µM) but not in thymidine kinase (TK)-deficient Raji/TK^- cell cultures (ED_{50}: > 500 µM), pointing to a pivotal role of cellular TK in the metabolic activation of FddClUrd. Unlike AZT, FddClUrd did not cause a blockage of thymidylate kinase. FddClUrd was also less toxic to bone marrow cells than AZT. In conclusion, the 5-halogeno FddUrd derivatives, and in particular FddClUrd, should be further pursued for their potential in the treatment of AIDS.

Th.C.0.21

CONFORMATIONAL PREFERENCE OF ANTI-HIV NUCLEOSIDES AND DRUG DESIGN

P. Van Roey†; C.K. Chu*; E.W. Taylor*; R.F. Schinazi#.
†Medical Foundation of Buffalo, Buffalo, New York 14203, *University of Georgia College of Pharmacy, Athens, Georgia 30602, #Emory University School of Medicine/VA Medical Center, Atlanta, Georgia 30033. U.S.A.

Objective. To study the molecular conformations of anti-HIV nucleosides for future drug design.
Methods. Molecular conformations of active as well as inactive nucleosides against HIV have been determined by X-ray crystallography.
Results. Active anti-HIV nucleosides show unusual conformational features in the glycosyl link geometry and sugar ring puckering. The active compounds have the extreme end of the range of observed anti-conformations. Ten of the eleven observations of active compounds have exceptional C3'-exo sugar conformations. The inactive nucleosides on the other hand, have C3'-endo conformations. The correlation between the extreme glycosyl link conformation and sugar ring puckering is significant.
Conclusion. These differences in conformations between active and inactive nucleosides result in a significant difference in the position and orientation of the 5'-hydroxyl group. Because the phosphorylation at 5'-position of the carbohydrate moiety is the initial and essential activation step in the mechanism of action of these compounds, these conformational differences may account for the activity difference. Furthermore, this information may allow us to design new anti-HIV agents.

(Supported by USPHS Grants AI 26055, AI 25899, CA 34769 and Veterans Administration)

Th.C.0.22

SYNTHESIS AND IN VITRO FUNCTION OF RIBOZYMES TARGETED TO HIV-1 SPECIFIC RNA SEQUENCES

Rossi, J.*, Chang, P.*, Stephens, D.**, Ladne, P.**, Cantin, E.** and Zaia, John A.**, *Beckman Research Institute of the City of Hope and **City of Hope Medical Center, Duarte, Calif. U.S.A.

Objective: To design and test autocatalytic RNA specific for HIV-1
Methods: We have utilized two classes of catalytic ribozymes targeted to HIV-1 RNA: one class (RBZ) is targeted to a site within the gag gene containing part of the required autocleavage site (GAAAC----GUX). The remainder of the required sequence (CUGAXGA) is supplied in trans along with flanking sequences to promote specific hybrid formation. The second class of ribozyme (GUX-RBZ) is patterned from Haseloff and Gerlach (Nature 34: 585, 1988) and contains all required sequences for auto-cleavage (except the target site GUX) along with appropriate flanking sequences to promote hybridization to a specific GUX site in the HIV-1 RNA. RBZ and GUX-RBZ were synthesized by in vitro transcription, purified by PAGE, incubated under varying conditions with the target HIV-1 RNA transcripts, and analyzed by PAGE and autoradiography.
Results: GUX-RBZ targeted to gag cleaved the HIV-1 RNA more efficiently than did RBZ. The GUX-RBZ cleavage reaction is entirely magnesium dependent, optimal at 20mM $MgCl_2$ and 45°C. GUX-RBZ is catalytically active from 22°C to 65°C and completely cleaves large molar excesses of substrate.
Conclusion: RBZs can be designed which can potentially target any GUX site in the HIV-1 genome and deserve evaluation as potential antiviral agents.

Th.C.O.23

ESTABLISHMENT OF HUMAN ASTROCYTOMA CELL CLONE CONSTITUTIVELY EXPRESSING THE HIV-NEF PROTEIN.

Bachelerie, Francoise.; Israël, N. and Virelizier J.L.
Laboratoire d'Immunologie Virale, Institut Pasteur, Paris, France.

Objective. To obtain a nef stably transfected cell line to study possible interferences of the nef protein with cellular activation pathways leading to HIV reactivation.
Methods. Segments (8068/9013 and 8068/384) of the HIV-1 (LAV-1-Bru) containing the nef ORFwere cloned under the control of different viral promoters including that of human cytomegalovirus immediate early gene, major late adenovirus 5 gene and HIV-1-LTR.Such vectors were cotransfected with a neomycine resitant gene expression vector using electroporation technique in the U373 MG human astrocytoma cell line.The selection of resistant clones was performed using G 418.
Results. Nef expression during the selection process was monitored by immunofluorescence assay and northern blot analysis. Stable selection of cellular clones containing the nef gene was obtained, as shown by northern and southern blot analysis and immunocharacterisation of the protein. In a fonctionnal assay we have used a Δ-NRE (deletion in the LTR of the segment upstream position -158) LTR-CAT vector to validate the notion that a region upstream of the enhancer participate in the regulatory effects of nef on HIV-LTR.
Conclusions. The availability of human cells constitutively expressing the HIV-nef protein makes it possible to investigate the role of nef in the activation pathways leading to HIV-LTR transactivation, as it is presently done in transient assay in our laboratory using stimulation with phorbol esters, tumor necrosis factor or c-Ha-ras gene co-transfection.

Th.C.O.24

TWO WEST-AFRICAN ISOLATES OF HIV-2 WITH MARKED TROPISM FOR MACROPHAGES, ONE OF WHICH IS HIGHLY DIVERGENT AND GENETICALLY EQUIDISTANT BETWEEN HIV-2_{ROD} AND SIV_{MAC}

Rübsamen-Waigmann, H., Adamski, M., Esser, R., Meichsner, C.*, Kühnel, H., von Briesen, H. and Dietrich, U.
Chemotherapeutisches Forschungsinstitut Georg-Speyer-Haus, Paul-Ehrlich-Str. 42-44, 6000 Frankfurt 70 and *Hoechst AG, 6000, Frankfurt 80, FRG

Objective Biological and genetic variation of human immunodeficiency viruses type 1 is increasingly being recognized. This study was aimed at analysing the divergence within the family of HIV-2.
The HIV-2-related viruses from a Gambian dying of exclusively neurological symptoms and from an asymptomatic Ghanesian exhibited on lymphocytes a growth typical for HIV-1 strains of the biological subtype c (slow growth with eventual high particle production and little or no cytopathic effect). In contrast, on macrophages, both virus isolates grew to very high titres and induced giant syncytia.
Molecular cloning and restriction site analysis revealed genetic heterogeneity within each isolate as has previously been shown for HIV-1 (J. Med. Virol (1987) 23: 51 - 66). The strain from the neurological case displayed 13% divergence versus HIV-2_{ROD} and HIV-2_{NIHZ}. In contrast, the Ghanesian strain was found to be genetically equidistant between the known HIV-2-strains and SIV_{MAC} (23-25% divergence). Several of the proteins of this strain have a size different from HIOV-2_{ROD}.
Conclusion Our results demonstrate that HIV-2 is at least as divergent a virus family as is HIV-1. This Ghanesian isolate may represent yet another HIV-family.

Th.C.O.25

CHARACTERIZATION OF A BIOLOGICAL VARIANT OF HIV-1, DEFECTIVE IN THE ABILITY TO MODULATE CD4.

Hoxie, James A.*; Inoue, M.†; Durda, P.§, Spirtos, M.*; Haggarty, B.*; Bonser, S.*; Reddy, E.P.† *Hematology-Oncology Section, Hospital of the University of Pennsylvania, Philadelphia, PA, USA, †Wistar Institute of Anatomy and Biology, Philadelphia, PA, USA, § E.I. du Pont de Nemours & Co, North Billerica, MA, USA.

Objective- Infection of peripheral blood lymphocytes and CD4+ cell lines by HIV has been shown to downmodulate the,CD4 molecule from the cell surface. In order to define the viral factors that mediate this effect we attempted to derive variants of HIV-1 that were unable to reduce CD4 expression on infected cells. Methods- Sup-T1 cells, productively infected with the IIIB strain of HIV-1 were cloned by limiting dilution and cloned lines evaluated for surface expression of CD4 using monoclonal antibodies that have been shown either to compete (OKT4A) or not to compete (OKT4) with the viral envelope for binding to CD4. Envelope binding to CD4 was determined by immunoprecipitation, and NEF expression was evaluated by Western blot using a monoclonal antibody specific for the HIV-1 NEF protein. Results- Of 30 cellular clones evaluated, one clone designated A1.25, exhibited high levels of CD4 expression as determined by OKT4 but was nonreactive with OKT4A indicating that CD4 was bound to the viral envelope but not downmodulated from the cell surface. These cells were 100% infected as determined by IFA and produced high levels of RT in culture supernatants. The increased .CD4 expression seen in the A1.25 line resulted from a change in the virus, since Sup-T1 or CEM cells that were infected by the A1.25 virus also remained strongly reactive with OKT4. Both the mature external envelope and envelope precursor molecules of the A1.25 virus were able to bind and coprecipitate with the CD4 molecule. Interestingly, although a 27 kD doublet corresponding to the NEF gene product could be detected by Western blot in cell lysates of the uncloned HIV-1 infected Sup-T1 cells, no NEF protein was observed in the A1.25 cell line. Conclusion- These studies demonstrate that binding of HIV envelope and envelope precursor molecules to CD4 can occur without CD4 modulation. Although the absence of NEF expression in the A1.25 infected cells is consistent with the proposed role of this protein in modulating CD4, we have shown that other isolates of HIV-1, which contained site-directed mutations in the NEF gene, are still able to modulate CD4 in the absence of the NEF protein. Infectious molecular clones of the A1.25 virus have been obtained and an analysis of their molecular and biological properties should be helpful in identifying specific viral determinants that affect CD4 expression.

Th.C.O.26

MURINE MONOCLONAL ANTIBODIES TO A SYNTHETIC PEPTIDE OF HIV-1 HAVE NEUTRALIZING AND FUSION BLOCKING ACTIVITIES.

Paul J. Durda*, K. Weinhold**, T. Matthews**, M. Rayner*, L. Bacheler*, and R. Pomerantz***, *E.I. du Pont de Nemours and Co.,

** Duke University, School of Medicine, Durham, NC 27710
***Massachusetts General Hospital, Infectious Disease Unit, Boston MA, U.S.A.

We have developed a series of murine monoclonal antibodies (MAbs) to a region of the 120kD envelope glycoprotein of HIV-1 which has previously been implicated as a site for virus neutralization. The antigen employed was a synthetic peptide containing 15 amino acids, representing amino acid residues 308-322, RIQRGPGRAFVTIGK, a hypervariable region of env gp120 (HTLV-3B isolate). Five of the MAbs have reactivity with gp120 in Western blots, four of these block fusion of HIV-1(3B) infected cells with uninfected cells with one also blocking fusion of a number of HIV-1 isolates including MN. At least two show reactivity in immunofluoresence assays with both fixed and live cells, and one has been found to neutralize HIV-1(3B) in vitro. These MAbs have been fine mapped using different synthetic peptides and each MAb has been found to have a different reactivity profile. Reactivities with peptides representative of aa's 308-322 of different HIV-1 strains appear to be predictive of the reactivitities of those MAbs with those actual isolates in various biological assays. For example the one MAb which reacts strongly with aa's 308-322 of the MN isolate (both by direct binding in ELISA and in peptide inhibition of binding of the MAb to aa's 308-322 of 3B) was the only MAb that blocked fusion of the MN infected cells with uninfected cells and that showed significant binding to MN infected cells as determined by FACS.

Th.C.O.27

INHIBITION OF HIV PRODUCTION BY INFECTED CELLS USING MONOCLONAL ANTIBODIES TO CD4

F. REY, P. CORBEAU, G. DONKER and J.C. CHERMANN
Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cédex 9. FRANCE

Objective : to investigate the role of CD4 in differents steps of virus - cell interaction : virus binding and entry, virus particle release or virus production and/or syncitia formation.
Methods : Using monoclonal antibodies to CD4, directed to differents epitopes of the V1 domain or other domains of the CD4 molecule (OKT4-A, 13B8.2, BL4), we have tried to block these differents steps of virus - cell interaction in 3 differents protocols established to study separatly each step. 6 strains of HIV1 or HIV2 have been studied either on CEM cell line or PHA stimulated PBL.
Results : Virus entry was inhibited by OKT4-A, but not by 13B8.2, or BL4, however this inhibition was not observed with all the strains studied.
More surprisingly, an inhibition of virus production was observed when cells were immediatly after infection and continuously cultured with 13B8-2, but not OKT4-A, or BL4.
These inhibition was a delay in virus release, viral strain dependent (from 6 to 38 days). While under protection, viral antigens are still detected in treated cells. The recovered virus from protected cells was different from the starting infectious virus.
Conclusion : Monoclonal antibodies to the V1 domain of CD4 are not only able to block virus entry and infectivity, but moreover, they can inhibit virus production. The inhibitory role of the antibodies in these 2 steps of virus - cell interaction is viral strain dependent.
Preliminary results are suggesting a direct inhibition at the level of the viral particle release from the cell, by the monoclonal antibodies to CD4.
Taken together, the results are suggesting a role for CD4 not only in virus binding and entry but moreover, a role for CD4 in virus particle release from the infected cells.

Th.C.O.28

HIV ISOLATES FROM ASYMPTOMATIC MEN ARE BIOLOGICALLY AND GENETICALLY DIFFERENT FROM THOSE ISOLATED FROM AIDS PATIENTS

Gupta, Phalguni; Balachandran, R.; Thampatty, P.; and Rinaldo, C.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To compare in vitro infectivity, replication properties and genomic structure of random and longitudinally obtained HIV isolates from asymptomatic men and AIDS patients.
Methods. HIV isolates were examined for their in vitro infectivity of CD4+ H9 cells, and DNA and RNA synthesis by hybridization with an HIV probe. Viral protein synthesis was measured by the radioimmunoprecipitation. The viral genomic structure was compared by restriction endonuclease analysis of high M.W. cellular DNA.
Results. Most of the HIV isolates from asymptomatic men, but not from AIDS patients, failed to infect CD4+ H9 cells and PHA-stimulated PBL. However, in asymptomatic HIV seroconverters who developed AIDS, longitudinal HIV isolates at all stages of infection could infect H9 cells; in contrast, longitudinal isolates from men who remained asymptomatic did not infect H9 cells. HIV isolates from AIDS patients exhibited increased production of virus particles and intracellular viral DNA, RNA and protein as compared with isolates from asymptomatic men. Isolates from asymptomatic men produced very little gp120, vif, and nef proteins as compared to isolates from AIDS patients. Certain restriction endonuclease patterns, such as Bgl II, were quite distinct for isolates from asymptomatic men as compared to AIDS patients.
Conclusion. HIV isolates from asymptomatic men are biologically and genetically distinct from those of AIDS patients. Such differences may be related to the various clinical outcomes of HIV infection.

Vaccins : étude de l'immunisation à l'aide des glycoprotéines du VIH
Vaccines: Immunization Study Using HIV Glycoproteins

Th.C.0.29 EPITOPES RECOGNIZED BY THE NEUTRALIZING ANTIBODIES OF AN HIV-1 INFECTED INDIVIDUAL

Profy, Albert T.*; Salinas, P.*; Eckler, L.*; Nara, P.**; Matthews, T.***; Langlois, A.***; et al.
*Repligen Corporation, Cambridge, MA, USA; **National Cancer Institute, Frederick, MD, USA; ***Duke University Medical School, Durham, NC, USA.

Objective. To determine the extent to which broadly neutralizing antibodies raised by an HIV-1-infected individual recognize the principal neutralizing epitope of the envelope protein gp120 (amino acids 296-331).
Methods. Broadly neutralizing serum from an antibody-positive, asymptomatic donor was subjected to affinity chromatography on immobilized peptides corresponding to the neutralizing epitope of three viral isolates. Effluent and eluate fractions were assayed for inhibition of HIV-mediated cell fusion and for neutralization of each of the three isolates.
Results. Most of the antibodies that neutralize one isolate were absorbed by peptides corresponding to its 296-331 envelope sequence. By contrast, most of the antibodies that neutralize the other two isolates were not absorbed by the immobilized peptides.
Conclusions. Infected humans seem to raise a type-specific neutralizing response against the principal neutralizing epitope of one isolate. Broad neutralization appears to result from the recognition of other epitopes as yet unidentified.

Th.C.0.30 NEUTRALIZATION OF IN VIVO HIV-1 INFECTIVITY MEDIATED BY IN VITRO NEUTRALIZING ANTIBODY

Emini, Emilo A.*; Eichberg, J.**; Nara, P.L.***; Lewis, J.A.*; Matsushita, S.****; Putney, S.D.***** et al.
*Merck, Sharp and Dohme Research Laboratories, West Point, PA, **Southwest Foundation for Biomedical Research, San Antonio, TX, ***NCI-Frederick Cancer Research Facility, Frederick, MD, ****Kumamoto University Medical School, Japan, ***** Repligen Corporation, Cambridge, MA, U.S.A.

Objective. To determine if an association exists between the ability of antibody to neutralize HIV infectivity in vitro and its ability to prevent HIV infection in vivo.
Methods. Titrated chimpanzee challenge inocula of HIV-1 (isolate HTLV-IIIb) were individually incubated in vitro with (1) virus- neutralizing IgG from an HIV-seropositive chimpanzee, (2) a specific neutralizing monoclonal antibody (0.5e), (3) non-neutralizing IgG from an HIV-seropositive human, (4) IgG from an uninfected chimpanzee. Both neutralizing antibody preparations were directed against the gp120 major neutralizing determinant. Each virus-antibody mixture was inoculated into a susceptible chimpanzee.
Results and Conclusions. The polyclonal neutralizing IgG inhibited in vivo HIV infection by the criterion of specific anti-HIV antibody development in the challenged animal. Similarly, the monoclonal neutralizing antibody decreased the infectiousness of the challenge virus. No effect was noted with either the non-neutralizing anti-HIV IgG or the control IgG. A correlation appears to exist between the ability of antibody to neutralize HIV infectivity in vitro and its ability to inhibit HIV infection in vivo.

Th.C.0.31 STUDIES OF HYPERVARIABLE REGION DELETION MUTANTS OF HIV-1 GP120

Haigwood, Nancy L.; Moore, G. K.; Mann, K. A.; Pruyne, P. T.; Skiles, P. V.; Steimer, K. S. *et al.* Chiron Corporation, Emeryville, California, U.S.A.

Objective. To determine the role of hypervariable regions in the structure , function, and immunogenicity of HIV-1 gp120.
Methods. Sequences encoding the five major hypervariable domains of the gp120 region of the envelope gene were deleted using site-directed mutagenesis. These deletions encompassed amino acids (aa) 131-154 (V1), aa 156-198 (V2), aa 300-332 (V3), aa 388-414 (V4), and aa 457-463 (V5). The resulting variants were produced intracellularly in yeast as nonglycosylated polypeptides and as secreted, glycosylated proteins in mammalian cells. CD4 binding of each gp120 variant was measured by radioimmune precipitation of gp120 variants and recombinant, soluble CD4. Purified yeast-derived variants were used to hyperimmunize test animals. ELISA titers versus the immunizing antigen and virus neutralization titers against HIV-SF2 and HIV-BRU were determined using standard techniques.
Results. Denatured, nonglycoslyated yeast-derived wild type gp120 did not bind to CD4, while purified or unpurified mammalian cell-derived glycosylated gp120 bound CD4 as well as gp120 from virus-infected cells. Mammalian cell-derived deletion variants of any or all of the three hypervariable sequences in the C-terminal half of gp120 (V3, V4, V5) resulted in CD4 binding that was at least 100-fold reduced relative to wild type gp120. In contrast, deletion of the variable sequences in the N-terminal half of the protein (V1, V2) did not perturb CD4 binding. In immunogenicity studies, denatured, nonglycosylated gp120 polypeptides deleted in one to three hypervariable regions, including deletion of variable region V3, elicited type-specific neutralization in guinea pigs and goats. However, the nonglycosylated protein with deletions of all five hypervariable regions failed to generate neutralizing activity, although it elicited high titer antibody responses.
Conclusion. Hypervariable regions play a major role in the immunogenicity of nonglycosylated versions of gp120 and may influence the structure of glycosylated gp120 and its binding to CD4.

Th.C.0.32 ANTIBODY DEPENDENT CELLULAR CYTOTOXICITY (ADCC) FOLLOWING VACCINATION WITH A RECOMBINANT HIV-1 GP160 VACCINE

Gorse, Geoffrey*; Newman, F.*; Belshe, R.B.*; and NIAID, AIDS Vaccine Program**.
*Marshall University, Huntington, WV, USA, **Bethesda, MD, USA.

Background: Sera from asymptomatic HIV-1 infected patients are more likely to mediate ADCC than sera from AIDS patients. Thus, stimulation of serum ADCC activity may be a desirable goal in the development of an AIDS vaccine.
Objective: To measure ADCC activity in sera obtained from persons in an rGP160 (MicroGeneSys) vaccine trial.
Methods: We tested sera from four adult vaccinees who developed antibody to GP120 on Western Blot after three doses of 40μg or 80μg of rGP160, and one placebo recipient whose Western Blot remained negative for anti-HIV-1 antibody. Target cells were HIV-1 infected and uninfected 12D7 cells (a variant of the CEM T-cell line) which were labeled with $[^{51}Cr]$ and incubated with vaccinee sera and control Western Blot positive sera from HIV-1 infected patients at dilutions of 1:5 to 1:40. PBL from normal healthy adults served as effector cells at an E:T ratio of 50:1. Percent ADCC was measured as antibody dependent minus antibody independent lysis.
Results: Sera from one vaccinee demonstrated a transient increase in percent ADCC; this vaccinee received 80μg doses of rGP160. None of 3 other vaccinees nor the placebo vaccinee manifested significant percent ADCC during the study.
Conclusion: We conclude that rGP160 at the two dose levels tested did not induce significant persisting antibody which mediated ADCC.

Th.C.0.33 SAFETY AND IMMUNOGENICITY OF HIV-1 RECOMBINANT GP 160 VACCINE CANDIDATE IN NORMAL VOLUNTEERS.

Dolin, Raphael*, Graham, B**, Greenberg, S**, Tackett, C**, Belshe, R**, Clements, M**, Fernie, B**, Stablein, D**, Smith, G***, and Koff, W**, *University of Rochester, Rochester, NY, **NIAID AIDS Vaccine Evaluation Group, and ***MicroGeneSys, Inc., West Haven CT, U.S.A.

Objective: To assess the safety and immunogenicity of two dosages of an HIV envelope glycoprotein (rgp160) vaccine in normal volunteers.
Methods: Recombinant HIV-1 glycoprotein (rgp160), prepared using a baculovirus vector (MicroGeneSys) was studied in 72 normal volunteers in a multicenter study, employing a double-blind, controlled experimental design. 18 subjects received 40 ug of rgp160, 18 received 80ug of rgp160, 18 received hepatitis B vaccine, and 18 received placebo. 3 intramuscular immunizations were employed (days 0, 30, 180). Subjects were followed for clinical and laboratory toxicities for up to 1 year. Serum antibody responses were determined by Western blot (WB), ELISA, and neutralization (Nt) assays.
Results: 39 females and 33 males participated, and 67 subjects received all three immunizations. Rgp160 was well tolerated, and there were no differences in acute reactions among the groups. There were also no differences in WBC, T4, T8, platelet counts or Hb levels among the groups. Serum antibodies to gp120 detected by WB were first noted at day 44 in 4/17 subjects at the 40ug dose, and in 8/17 at 80ug. At day 194, 14/17 at the 40 ug dose and 13/17 at the 80ug dose were seroreactive by WB. Antibody reactivity to gp160 and gp41 was seen less frequently. ELISA antibodies appeared generally later and less frequently than WB antibodies. Studies of Nt antibodies are currently underway.
Conclusion: This rgp160 vaccine candidate is well tolerated and non-toxic in normal volunteers, and induced high rates of serum antibody responses as detected by WB.

Th.C.0.34 T CELL RESPONSES TO HIV IN HUMANS IMMUNIZED WITH RECOMBINANT VACCINIA VIRUS CONTAINING HIV ENVELOPE

Cooney, Elizabeth L.*; Zarling, J.**; Hu, S.L.**; Watson, A.**; Corey, L.* and Greenberg, P.*. *University of Washington, and **Oncogen, Seattle, WA USA

Objective: To study T cell responses to HIV antigens and vaccinia (Vac) virus in a Phase I vaccine trial with a recombinant vaccinia virus containing the HIV gp160 gene (HIVAC-1e).
Methods: 30 subjects were vaccinated and then boosted 8 weeks later with either wild-type Vac or HIVAC-1e. T cell *in vitro* proliferative responses to a panel of antigens were determined pre- and at 4-week intervals post-vaccination. *In vitro* stimuli were several HIV antigen preparations including UV-psoralen inactivated HIV, live HIV, and gp160; immunogens including Vac, HSV, CMV, tetanus toxoid, and Candida; and mitogens including PHA, Con A and PWM.
Results: T cell responses and serum neutralizing antibody to Vac were detectable pre-vaccination in all 28/30 subjects previously immunized to Vac, including 13/15 recipients of HIVAC-1e. Vaccination with HIVAC-1e significantly boosted the T cell response to Vac in 7/13,and this correlated with a 4-fold rise in the serum antibody titer. The 2 HIVAC-1e recipients with no detectable immunity to Vac pre-vaccination both developed strong *in vitro* proliferative responses and serum antibody titers to Vac following priming. The second inoculation of Vac or HIVAC-1e at week 8 minimally augmented the proliferative T cell responses of the 30 subjects to Vac.

Of the 13/15 HIVAC-1e recipients with pre-existing immunity to Vac, 5 developed low and/or transient responses to one of the HIV antigen preparations. By contrast, the 2 HIVAC-1e recipients naive to Vac developed strong persistent proliferative responses to HIV antigens post-vaccination. No significant HIV responses were detectable in Vac recipients. The responses to non-HIV antigens and mitogens were not affected by vaccination with either Vac or HIVAC-1e.
Conclusion: Vaccination of individuals lacking pre-existing immunity to Vac with a recombinant Vac expressing gp160 elicits strong T cell proliferative responses to HIV, and studies are in progress to define the CTL responses in these individuals. Individuals previously vaccinated demonstrate persistent immunity to Vac and are variably primed to HIV antigens by vaccination, and studies to further characterize and augment these responses are being performed.

Th.C.0.35 THE IMMUNOGLOBULINS (Igs) EXPRESSED BY AIDS-ASSOCIATED B CELL LYMPHOMAS (AL) CONTAIN SHARED IDIOTOPES (SIds) AND ARE REACTIVE WITH HIV ANTIGENS.

Miller, Richard*; Hart, S.*; Wing, L.*; Samoszuk M.**; Herndier, B.*** and McGrath, M.***
*IDEC Pharmaceuticals Corp., Mountain View, CA, **University of California Irvine, Irvine, CA, ***University of California San Francisco, San Francisco, CA, USA.

Objective. The Ig idiotypes of AL were analyzed using a panel of anti-idiotype antibodies (AIAbs).
Methods. A panel of 19 AIAbs specific for lymphoma SIds was tested for reactivity against AL and non-AIDS B cell lymphomas. Idiotypes expressing SIds were isolated from AL and tested for HIV reactivity.
Results. Five AIAbs were found to cross-react with AL as shown below.

AIAb	AIDS-High Grade	Non-AIDS High Grade	Low Grade
S2-33	12/24 (positive cases/total)	0/13	8/155
S30-47	2/10	0/13	4/155
B4/11	1/10	1/13	0/129
L50-19	1/10	0/13	0/155
S37-48	1/10	0/13	6/149

The AIAb S2-33 reacted with 50% of AL tested. In total, these 5 AIAbs reacted with at least 17/24 (70%) of AL. These AIAbs reacted with only 1/13 non-AL (high grade lymphomas) and 12% of low grade lymphomas. Id was rescued from two AL and found to react with HIV gp120 and p65 respectively.
Conclusion. AL express Igs which have SIds and HIV binding activity.

Th.C.0.36 ANAL HPV INFECTION AND CYTOLOGIC ABNORMALITIES IN HIV-INFECTED INDIVIDUALS

Palefsky, Joel, Gonzales, J., Hollander, H. and Greenblatt, R. University of California, San Francisco, California, U.S.A.

Objective. Anal cancer may be up to 25 times more common in homosexual males than age-matched heterosexual controls and patients with AIDS may be at particularly high risk. Similar to its role in cervical cancer, human papillomavirus (HPV) may play a role in the development of anal cancer. The goal of this study was to determine the prevalence of anal HPV infection as well as cytologic abnormalities which may represent precursors to anal cancer. Methods. Sixty-eight male patients underwent insertion of a swab to the anorectal junction for cytology, followed by a second swab for HPV DNA hybridization studies. HPV DNA typing on these specimens was performed using RNA:DNA hybridization with a screening mixture of HPV 6,11,16,18,31,33 and 35 RNA probes. Results. Twenty-nine smears (43%) were abnormal using cytologic criteria similar to those in use for cervical intra-epithelial neoplasia and condyloma; 15 (22%) samples showed anal intra-epithelial neoplasia (AIN) 1, 5 (7%) samples showed AIN 2, and 9 (13%) samples showed condyloma. Forty-five of the 68 specimens (66%) were found to be HPV DNA-positive. Of the patients with abnormal cytology, 79% were positive for HPV, whereas 57% of the patients with normal cytology were positive for HPV DNA ($p<.05$). Preliminary studies grouping the samples positive for HPV into types 6/11, 16/18 or 31/33/35 indicate that type 16/18 was detected in 50% of the positive samples, 31/33/35 in 40% and 6/11 in 17%, with double infection in some specimens. Conclusion. Anal HPV infection and cytologic abnormalities were very common in homosexual men with AIDS and ARC. Although HPV DNA was detected in a large number of males without cytologic abnormalities, a significant association between AIN/condyloma and HPV infection was found. It is not yet known if AIN represents a true precursor of anal cancer and therefore the significance of these findings is not yet known; prospective follow-up studies are in progress.

Th.C.0.37 A COMMON CELL SURFACE IMMUNOGLOBULIN IDIOTYPE IN HIGH-GRADE LYMPHOMAS AND IN PRELYMPHOMATOUS REACTIVE LYMPH NODES IN HIV-INFECTED INDIVIDUALS.

Herndier Brian*, Khayam-Bashi F*, Kaplan L*, Miller R**, Meeker T***, McGrath MS*.
*University of California, San Francisco, and San Francisco General Hospital, San Francisco, California, USA, **IDEC Pharmaceuticals, Mountain View, CA, USA, and ***UCSF/Veterans Administration Medical Center, San Francisco, CA, USA.

Objective: To determine the role of viral-associated antigen interaction with B-cell idiotypes in the pathogenesis of AIDS-associated non-Hodgkin's lymphoma (A-NHL).
Methods: Immunoperoxidase staining of frozen tissue sections, indirect immunofluorescence, immunoglobulin gene rearrangement analysis by Southern blotting.
Results: An IgM murine monoclonal anti-idiotypic antibody (S2.33) directed against an epitope unique to a low grade follicular lymphoma bound to 1) an immortalized EBV-negative Burkitt's lymphoma B-cell line (10C9), 2) an immunoblastic lymphoma (IBL), 3) several AIDS-associated B-cell lymphomas (see R. Miller, et al., abstract, this meeting), and 4) a large proportion of B-lymphocytes in reactive follicular hyperplastic lymph nodes from 3 HIV-infected individuals (one individual subsequently developed a high grade IBL). The Burkitt's lymphoma was monoclonal, whereas the IBL and the follicular hyperplastic nodes were polyclonal. Affinity purified IgM secreted by the 10C9 cell line bound to an HIV-infected T-cell line, but did not bind to an HTLV-I infected or uninfected T-cell line.
Conclusion: These findings of a shared idiotype on both monoclonal and polyclonal B-cell populations isolated from HIV-infected individuals suggests a monospecific process occurring during the evolution of A-NHL. Since the 10C9 lymphoma idiotype is directed against antigens on HIV-infected cells, the pathogenesis of A-NHL may include antigen-dependent steps.

Th.C.0.38 PRESENCE OF EPSTEIN-BARR VIRUS BY IN-SITU HYBRIDIZATION IN NON-HODGKIN'S LYMPHOMAS OF AIDS PATIENTS

Jeannette Guarner*; del Rio C.+; Hendrix L.+; Unger E.R.*
*Emory University and +Crawford Long Hospital of Emory University, Atlanta, Ga. 30322, U.S.A.

Objective. The majority of non-Hodgkin's lymphomas (NHL) occurring in AIDS patients are high grade malignant lymphomas of immunoblastic or small, non-cleaved cell type. The latter bear histologic similarities to African Burkitt's lymphoma where EBV is thought to play an etiologic role. We searched for an association of EBV with NHL of various histologic types in AIDS patients.
Methods. In-situ hybridization was performed on formalin or B5 fixed paraffin embedded tissues from 13 AIDS patients with NHL using biotinylated portions of the EBV genome (Bam H1 fragments K, A, V and Y/H) and colorimetric detection.
Results. EBV signal was demonstrated in the nucleus and cytoplasm of the neoplastic cells from 9 of the 13 NHL; 6/6 diffuse small noncleaved cell type (Burkitt's lymphoma), 2/4 diffuse large cell type, 1/2 diffuse large cell immunoblastic lymphoma, 0/1 low grade lymphoplasmacytoid lymphoma.
Conclusions. Our data show a consistent association of EBV with the small noncleaved lymphomas in AIDS. In other histologic varieties EBV was associated in about half of the cases. This association warrants further investigation into the etiologic role of EBV in AIDS related lymphomas.

Th.C.0.39 *DIFFERENCES BETWEEN BURKITT'S AND NON-BURKITT'S HIGH GRADE LYMPHOMAS (HGL) ASSOCIATED WITH HIV INFECTION.*

Andrieu, Jean-Marie ; Raphael, M. ; Gentilini, M. ; Tourani, J.M. ; Dupont, B.; Armengaud, M.; for the French HIV-associated tumors registry (HATR). Oncology/Hematology. Laennec hospital, 42 rue de Sèvres -75340 PARIS - CEDEX 07 - FRANCE.

From 1.87 to' 9.88, 102 HGL were recorded in the HATR: Burkitt's lymphomas (BL) 39, Non-Burkitt's lymphomas (NBL) 63 (immunoblastic 28, Large cell or predominantly large cell 33, histiocytic 2); route of HIV infection : Male homosex 61, IVDA 11, both 5, heterosex (Europe plus Africa) 11, others and not available 14. Initial characteristics of BL and NBL are given in the Table.

	Available	*BL*	*NBL*	*P Value*
All Patients	*102*	*39*	*63*	*-*
Sex M/F	*102*	*36/3*	*59/4*	*NS*
Age Min/Max	*99*	*20/72*	*19/73*	*NS*
Median		*40*	*38*	
Stage I-IV/Extra-Nod	*101*	*38/1*	*38/4*	*0.00004*
HIV+/AIDS	*96*	*33/4*	*33/26*	*0.0006*
CD4 Cell/ul Min-Max	*59*	*21-1125*	*0-288*	*0.02*
Mean		*291*	*121*	

We conclude that there are significant differences between BL and NBL for clinical presentation (stage I-IV VS extra-nodal only) and BL occurs earlier than NBL in the course of HIV infection. Etiopathological implications of these differences will be discussed taking into account both B and T cell disorders of HIV disease.

Th.C.0.40 HIV-RELATED TUMORS: A REPORT OF 435 CASES FROM GICAT (Gruppo Italiano Cooperativo AIDS & Tumori).

Tirelli Umberto, Vaccher E., Lazzarin A., Rezza G., Gavosto F., Monfardini S. et al, Centro di Riferimento Oncologico, 33081, Aviano, Italy.

Objective. To evaluate the epidemiology and natural history of HIV-related tumors in Italy. Methods. Through questionnaires sent to infectious disease specialists, hematologists and oncologists, the GICAT has since 1986 been collecting data on HIV-related tumors. Results. As of Sept. '88, 435 HIV-related tumors were recorded: 198 KS (9% of AIDS cases), 116 high grade NHL (6% of AIDS cases), 20 other NHL, 52 HD and 49 other tumors. In Italy intravenous drug abusers (IVDA) represent 67% of AIDS cases. The Table summarizes the main data regarding KS, high-grade NHL and HD:

	N°	MAIN GROUP	INCIDENCE	PECULIAR FINDINGS
KS	190	Homosexual men 65% IVDA 20%	Increased	Advanced stages↑↑; GI involvement↑ poor outcome
NHL high grade	116	IVDA 65%	Increased	Burkitt↑↑;CNS↑↑; extranodal↑ ; rare oral & anal involvement; poor outcome
HD	52	IVDA 85%	Probably increased	MC & LD↑; extranodal↑ ; Stages III & IV↑; poor outcome

Conclusion. In this IVDA-based series: 1) at least 15% of AIDS is associated with tumors; 2) the number of malignant lymphoma approaches that of KS; 3) KS among AIDS patients is less common (9%) than in countries where homosexual men are the main group affected by AIDS. However KS is not rare among IVDA with characteristics similar to those of homosexual men; 4) HD is associated with atypical and aggressive course; 5) oral and anal involvement of NHL as well as oral and anal cancers are very rare.

Le rôle des macrophages et des lymphocytes comme réservoirs du VIH-1
Role of Macrophages and Lymphocytes as Reservoirs of HIV-1

Th.C.O.41 ENTRY OF HIV INTO CELLS

McDougal, J. Steven*; Maddon, P.J.**; Orloff, G.*; Clapham, P.R.***; Dalgleish, A.G.***; Jamal, S.***; Kennedy, M.S.*; Orloff, S.*; Weiss, R.A.*** and Axel, R.A.**. *Centers for Disease Control, Atlanta, GA, USA, **Columbia University, New York, NY, USA, ***Chester Beatty Laboratories, London, UK.

Objective. To determine whether the CD4 molecule, which serves as an attachment protein (receptor) for HIV, also functions in the HIV internalization event.
Methods. Conditions for saturating cells with HIV and for synchronizing the penetration event were developed as were assays to detect CD4 internalization and HIV penetration. Mutations were introduced into the cytoplasmic segment of CD4 rendering cells that express these mutant CD4 molecules incapable of phosphokinase C-induced CD4 internalization.
Results. Tracking CD4 during HIV penetration failed to detect CD4 internalization. Induction of CD4 internalization did not enhance HIV infectivity nor did inhibition of CD4 internalization prevent HIV infection. Cells expressing CD4 mutant molecules that are incapable of internalization were, nevertheless, infectable by HIV.
Conclusion. HIV penetration does not require internalization of its receptor, CD4.

Th.C.O.42 ROLE OF MACROPHAGES IN PATHOGENESIS OF HIV

Gartner, Suzanne* and Popovic, M.**
*New Mexico State University Primate Research Institute, Alamogordo, New Mexico, USA, **National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA.

Both in vivo and in vitro studies clearly indicate that cells of the mononuclear phagocyte lineage play a key role in the pathogenesis of AIDS. To facilitate a more detailed analysis of HIV-1 interactions with cell types of this lineage, a cell culture system using normal monocyte/macrophages (MM) from peripheral blood has been developed. We have previously shown that MM are highly susceptible and permissive hosts for "fresh" HIV-1 isolates recovered from various tissues of virus-positive individuals. Utilizing this MM cell culture system, we will present data demonstrating that (a) cells of the mononuclear phagocyte lineage are principal sites of HIV-1 replication early in the course of the virus infection, (b) "freshly" recovered (not propagated in permanent cell lines) HIV-1 isolates are dual (MM and T cell) tropic, (c) in vitro-infected MM exhibit functional alterations similar to those observed in AIDS patients and (d) the most efficient HIV-1 transmission from MM to T cells occurs during specific antigen presentation.

Th.C.O.43 SURFACE RECOGNITION STRUCTURE FOR HIV

A.G. Dalgleish

MRC Clinical Research Centre, Harrow, HA1 3UJ, U.K.

The surface recognition structure for HIV is the CD4 molecules which binds to the gp120 component of the HIV envelope with a high affinity (10^{-9}M). This property is conserved amongst all isolates of HIV-1, SIV and HIV-2, although the affinity may be lower in the latter. This remarkable attraction of the envelope for such an important immunological ligand as CD4 may well explain the development of an acquired immunodeficiency without invoking direct cytopathic effect by the complete virus. Masking of the CD4 epitope by envelope may prevent antigen presentation and other CD4 dependent immunological functions, as well as leading to clonal deletion of activated CD4 cells by cytotoxic cells. These hypotheses may be investigated using soluble CD4 and soluble gp120. The detrimental effect of soluble gp120 in immunological response assays, and the beneficial effect of soluble CD4 in *in vitro* and *in vivo* virological systems suggests that soluble CD4 may have beneficial therapeutic effects even at doses much less than those required to have an antiviral effect *per se*, simply by inactivating soluble gp120 and free virus. Vaccine strategies based on gp120/CD4 have been examined using anti-CD4 monoclonal antibodies which may induce an internal image response mimicking the gp120 binding site on CD4 and therefore bind and neutralise a broad range of HIV isolates. These studies have now been extended to further characterise the anti-idiotypic response, the role of adjuvants and the response of the human immune system to anti-CD4 monoclonal antibodies.

Th.C.O.44 CYTOKINE INDUCTION OF HIV EXPRESSION

Fauci, Anthony S., National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland, USA.

We have previously established an in vitro model system for the study of the induction of expression of HIV in latently or chronically infected promonocytic (U-1) and T lymphocyte (ACH-2) cell clones. We have used these systems to demonstrate the induction of HIV expression in these cell lines by certain cytokines. Specifically, tumor necrosis factor (TNF)-alpha was capable of inducing HIV expression in both U-1 and ACH-2 cells. Other cytokines such as interleukin (IL)-6 and granulocyte-macrophage colony stimulating factor (GMCSF) were able to induce HIV expression in U-1 but not in ACH-2 cells. In addition, there was significant synergy between TNF-alpha and IL-6, and TNF-alpha and GMCSF in the induction of HIV expression in the U-1 cell line. The pathways of induction consisted of a transactivating mechanism whereby a DNA-binding protein was shown to selectively bind to the NFkB site of the HIV LTR. Most recent experiments have demonstrated an autocrine/paracrine loop involving the induction of HIV expression by TNF-alpha which in synergy with PMA can regulate its own expression. Furthermore, we have demonstrated that cytokine induction of HIV expression involves the direct or indirect activation of phosphokinase C (PKC) and that inhibitors of PKC can inhibit HIV expression. These model systems will be used to further delineate the precise mechanisms of HIV expression and, perhaps, the control of expression of HIV in infected cells.

Vaccins : utilisation d'un modèle animal pour l'étude des vaccins anti-VIH
Vaccines: Use of Animal Model to Study Anti-HIV Vaccines

Th.C.0.45 Immunization of Rhesus Macaques with Inactivated SIV Fails to Protect Against Mucosal or IV Challenge.

Sutjipto, S, Pedersen, N., Gardner, M.B., Hanson, C.V., Miller, C., Gettie, A., Jennings, M., Higgins, J. and Marx, P.A. University of California, Davis, Davis, CA., U.S.A.

Objective: To determine if immunization of rhesus macaques with an inactivated whole Simian Immunodeficiency Virus (SIV) vaccine protects against mucosal or IV challenge with live SIV.
Methods: Eight juvenile rhesus received 4 immunizations (2 mg total viral protein) of psoralen UV light inactivated SIV_{mac} with MDP adjuvant. Eight controls received adjuvant only. The humoral immune response before and after challenge was monitored by western blot and neutralization assays. The animals were challenged IV and by genital mucosa with 10-100x the minimal animal infectious Odse ($\leq$ 1TCID/50) of live SIV_{mac}. Viremia was assayed by cocultivation of PBMC with CEM x 174 cells and the number of infected cells was roughly quantitated by limiting dilution assay.
Results: The vaccinated monkeys made an adequate immune response as judged by immunoblot and neutralization assays and by comparison to our previous results with D-retrovirus vaccines. However, at 2 and 6 weeks after challenge with live SIV, by either IV or genital mucosal routes, virus was readily isolated from the PBMC of all 8 vaccinated rhesus and all 8 controls. The number of infected cells was not significantly different in the two groups.
Conclusion: Immunization of rhesus macaques with an inactivated SIV_{mac}-MDP vaccine failed to protect against viremia following challenge with live SIV_{mac} by the IV and genital mucosal routes.

Th.C.0.46 HIV IMMUNIZATION AND CHALLENGE OF HIV SEROPOSITIVE AND SERONEGATIVE CHIMPANZEES.

C. J. Gibbs,[1] C. Mora,[1] R. Peters,[2] F. C. Jensen,[2] D. J. Carlo[2] and J. Salk.[3] [1]NIH, Bethesda, MD; [2]The Immune Response Corporation, San Diego, CA; [3]The Salk Institute, San Diego, CA. U.S.A.

Objective: To determine the characteristics of the serologic response of HIV seropositive and seronegative chimpanzees to HIV immunization and to virus challenge.

Methods: Three adult chimpanzees (two seropositive and one seronegative) were inoculated I.M. (primary and 2 booster doses) with a gamma irradiated non-infectious HIV immunogen emulsified in incomplete Freund's adjuvant (IFA). Approximately 13-15 months after the initial immunization, these chimpanzees and an untreated control animal were challenged I.V. with 10 chimpanzee infectious doses of HIV. Western blots, ELISA's and tests for neutralizing antibody and for virus by co-cultivation of PBL were performed.

Results: The two previously HIV infected seropositive chimpanzees, A-86C and A-3, exhibited an anamnestic response to the first dose of immunogen; the initially seronegative animal, A-36, manifested a primary- and secondary-type response after the first and second doses, respectively. After challenge, A-86C and A-3 exhibited no evidence of infection virologically or serologically. In contrast, A-36 became virus positive after challenge and responded anamnestically to infection with a rise in anti-p24 antibody titer from 1:16,000 to 1:256,000. The control chimpanzee, A-189a, also became virus positive and exhibited only a primary-type antibody response to the virus infection (anti-p24 titer from negative to 1:8000).

Conclusions: 1) The resistance to reinfection observed in A-86C and A-3 suggests that the induction of immunity to infection by potentiating a noninfectious immunogen may be an attainable goal. 2) The anamnestic response following challenge observed in A-36, in contrast to the primary-type response to infection observed in A-189a, raises the possibility that induction of immunity to disease, through vaccine-induced immunolgic memory, may be achieved even if infection is not prevented.

Th.C.0.47 IMMUNOGENICITY OF POTENTIAL HIV VACCINES IN CHIMPANZEES

Girard, Marc[1] ; Kieny, M.P., and Lecocq, J.P.[2] ; Yagello, M., and Gluckman, J.C.[3] ; Barré-Sinoussi, F., and Montagnier, L.[4] ; Muchmore, E.[5] ; and Fultz, P.[6] - [1]Pasteur Vaccins, Marnes-la-Coquette, [2]Transgène, Strasbourg, [3]CHU Pitié-Salpêtrière, Paris, [4]Institut Pasteur, Paris France ; [5]LEMSIP, Tuxedo, NY and [6]Yerkes Primate Center, Atlanta, GA, USA.

Objective. To test the safety, immunogenicity and efficacy of potential HIV vaccines in chimpanzees.
Methods. Chimpanzees were immunized with multiple injections of vaccinia virus recombinants expressing gp160env and p25gag, followed by inactivated HIV formulated with Syntex adjuvant (SAF). Humoral and cellular HIV specific immunity was assessed.
Results. One animal, that had antibody (Ab) titers in the range of 1:100,000 (Western blot and ELISA) and sustained T-cell proliferative responses to purified HIV gp160, was challenged with 32 $TCID_{50}$ of the $LAV\text{-}1_{BRU}$ isolate injected I.V. Infectious virus was recovered from the animal's PBLs starting at 2 weeks after challenge, thus demonstrating lack of protection. A tenfold anamnestic response was observed in ELISA titer, followed by progressive appearance of Ab to pol, nef, and vif. Neutralizing Ab titers, however, remained low or below detection, even during 7 subsequent months. Two unchallenged animals that had undergone a parallel immunization course were repeatedly boosted with gp160 in SAF, with no significant increases in ELISA or neutralizing Ab titers.
Conclusion. A vaccination regimen involving a live recombinant vaccine, inactivated HIV and gp160 env induced good cell-mediated and humoral immunity, but only poor neutralizing activity, indicating that better presentations of virus neutralization epitopes must be devised to elicit protective immunity.

Th.C.0.48 Simian Immunity to HIV-1 Candidate Vaccines

P. Neumann and M.V. O'Shaughnessy, Bureau of Laboratories and Research Services, Federal Centre for AIDS, Ottawa CANADA
G. Smith and M. Cochran, MicroGeneSys Inc., West Haven, CT

The first HIV vaccine approved for clinical trial status by the U.S. FDA was that produced in a baculovirus-insect cell expression system by MicroGeneSys. We have studied the antibody response of 12 rhesus monkeys initially inoculated with various doses of the gp160 recombinant envelope protein. Immunoblot and neutralization assays on these monkey sera have shown a persistent, albeit, attenuated response one year after the final gp160 boost of 500 ug dose. A final boost of gp160 to two monkeys showed a characteristic anamnestic response as measured by immunoblot and neutralization assays. Ten animals had received boosters with a 3 dose regimen of a new p24 (gag) recombinant protein. This induced the anticipated immunoblot reactivity and also complemented the *in vitro* neutralizing capability due to gp160. The monitoring of the long term persistence of antibody (including neutralizing) is ongoing.

Th.C.0.49 VACCINATION WITH LIVE RETROVIRUSES: THE NATURE OF THE PROTECTIVE IMMUNE RESPONSE.

Ruprecht, Ruth M.*; Hom, R.*; Mullaney, S.*; Gama Sosa, M.* and Finberg, R*.
*Dana-Farber Cancer Institute, and Harvard Medical School, Boston, Massachusetts, USA.

Objective. To determine the nature of the protective immune response in animals vaccinated with a live, pathogenic retrovirus.
Methods. Adult female BALB/c mice were inoculated with live Rauscher Murine Leukemia virus (RLV) at time 0. Four hours after virus exposure, the animals were given post-exposure prophylactic therapy with 3'-azido-3'-deoxythymidine (AZT or Zidovudine) in combination with recombinant human interferonαA/D for 20 d. At the end of therapy, these animals were free of viremia and disease. On day 25, they were challenged with live RLV in the absence of antiviral therapy. Three weeks later, > 90% of these animals were found to be free of viremia and disease. Splenocytes from these immune animals were injected into syngeneic naive recipients either directly or after removing B cells or monocytes by passage through nylon wool columns, or after removal of various T-cell subsets. One hour after adoptive cell transfer, the recipients were challenged with live virus and left untreated for 3 weeks at which time they were sacrificed. Their spleens were weighed and analyzed for the presence of virus by immunoblot analysis.
Results. A dose of 4×10^7 unfractionated immune T cells was sufficient to protect naive recipient mice from virus infection and disease. Removal of cytotoxic immune T cells led to a drastic reduction in the number of recipient animals resistant to viral challenge. Passive serotherapy was not protective.
Conclusion. Live RLV, pharmacologically attenuated by combination therapy with AZT and recombinant human interferonαA/D, can elicit a protective immune response which is most likely due to the action of immune cytotoxic T cells.

Th.C.0.50 DEVELOPMENT OF AN HIV SUBUNIT VACCINE

Putney, Scott D.*; Javaherian, K.*; Profy, A.*; Rusche, J.*; Matthews, T.**; and Bolognesi, D.**.
*Repligen Corporation, Cambridge, MA, USA, **Duke University Medical School, Durham, NC, USA.

Objective. To develop an effective HIV subunit vaccine able to protect against infection by diverse HIV isolates.
Methods. Recombinant HIV vaccine candidates including the entire envelope, gp160, have been produced from several different HIV-1 isolates in *E. coli* and in insect cells and synthetic peptides of the envelope have been made. Animals including chimpanzees were immunized and the neutralizing antibody response was measured.
Results. The principal neutralizing epitope within gp160 was mapped to a hypervariable region of gp120(aa 308-331). Antibodies to this region neutralize free HIV and prevent CD4 cell fusion. Antibodies to this epitope delay HIV infection of chimpanzees (E. A. Emini, et al.). Antibodies to this epitope do not prevent binding of gp120 to CD4 and therefore neutralize HIV via a post-binding step. We are PCR sequencing this region from many isolates to uncover common elements. Chimpanzees immunized with gp160 formulated in ISCOM particles demonstrate neutralizing antibody titers comparable to those elicited by infectious HIV.
Conclusion. An immunogen, composed of either a cocktail or a hybrid polypeptide, incorporating this epitope from several HIV-1 strains may elicit protective immunity to many isolates. The ISCOM may be a useful adjuvant to present these immunogens.

Mise au point de médicaments et vaccins
Drug Development and Vaccines

M.C.P.1 DIFFERENTIAL VIRAL GENE EXPRESSION AND THEIR EFFECT ON THE BIOLOGICAL PROPERTIES OF CLONES OF AN HIV-1 INFECTED CELL LINE

Kalyanaraman, V.S.*, Rodriguez, V*, Josephs, S.**, Gallo, R.C.**, Sarngadharan, M.G.* *Bionetics Research, Inc., Rockville, MD, **National Cancer Institute, NIH, Bethesda, MD,U.S.A.

Objective: Analyze the biochemical and biological properties of HTLV-III$_{451}$ (6D5/451) which secretes both gp120 and gp160 in the extracellular medium.
Methods: Obtain single cell clones of 6D5/451 cells and examine their morphology by electron microscopy and ability to form syncytia with CD4 positive cells. Using metabolically labeled cells the expression of viral proteins was also analyzed.
Results: Three interesting clones secreting functional gp120 and gp160 in the medium were obtained. The first clone expressed viral reverse transcriptase (RT) and had both mature and immature virus particles. The second clone had mostly immature virus, expressed no RT or p24 and had only Pr^{53gag} in the cells. Both the clones formed syncytia when mixed with CD4 positive cells. The third clone expressed only gp120 and gp160 but did not form syncytia with CD4+ cells. All three clones had integrated full length genome when examined by restriction enzyme analysis.
Conclusion: Even minor changes in the genome of HIV-1 can lead to a preferential expression of the viral gene products which influence the biological properties of the infected cells.

M.C.P.2 PROTECTIVE VACCINE AGAINST FELINE LEUKEMIA VIRUS USING A RECOMBINANT ANTIGEN

Charlotte R. Kensil*; G.A. Beltz*; C.H. Hung*; A. Aubert**; and D.J. Marciani*, *Cambridge BioScience Corporation, Worcester, MA, USA, **Virbac Laboratories, 06516 Carros, France.

Objective. To produce a feline leukemia virus (FeLV) recombinant subunit vaccine.
Methods. The genetic information coding for the polypeptide portion of subgroup A FeLV glycoprotein gp70 was cloned into a PL-based expression vector. This polypeptide (rec-env) was expressed in E. coli and purified. Kittens were immunised three times with 100 ug rec-env, 20 ug purified saponin adjuvant, and aluminum hydroxide and challenged with 1 X 10^5 infectious FeLV particles.
Results. Vaccination induced neutralization titers ranging from 32-64 for subgroup A FeLV as well as cross-neutralization of subgroups B and C, anti-FOCMA titers of 125, and antibody affinity maturation during the course of immunization. A memory response was observed in vaccinates upon challenge. Control animals developed chronic viremia and pronounced lymphadenopathy within a month of challenge whereas vaccinated animals were nonviremic or developed a low transient viremia and were protected against disease.
Conclusion. A recombinant subunit vaccine based on subgroup A gp70 induces protection against FeLV.

M.C.P.3 CLINICAL EVALUATION OF EXPERIMENTAL AIDS VACCINES

Koff, Wayne C.*, Wescott, S.L., Novak, J., Stablein, D., Fernie, B., and Gerin, J. for the NIAID AIDS Vaccine Evaluation Group, Bethesda, Maryland, U.S.A.

The process of conducting clinical trials of AIDS vaccines poses significant scientific and logistical challenges including strategies for recruitment of volunteers, confidentiality, vaccine induced seroconversion, and other difficult ethical dilemmas. In order to accelerate the development of a safe and effective AIDS vaccine, the Vaccine Research and Development Branch of the AIDS Program, NIAID has established a multi-center cooperative clinical trials network. The AIDS Vaccine Clinical Trials Network consists of an AIDS Vaccine Selection Committee, and the NIAID AIDS Vaccine Evaluation Group (composed of AIDS Vaccine Evaluation Units, Data Coordinating and Analysis Center, Data and Safety Monitoring Board, Core Immunology Laboratory, and Central Repository). The capacity to clinically evaluate multiple AIDS vaccine approaches simultaneously has been instituted, and two candidate AIDS vaccines are currently being tested utilizing comprehensive core protocols. Ancillary research studies are also being done to ensure that maximum safety and immunogenicity data on each candidate vaccine is compiled. Guidelines and minimum criteria for candidate vaccines entering into Phase 1 and 2 clinical trials will be discussed, along with a detailed review of approaches developed to address the issues unique to the clinical evaluation of AIDS vaccines.

M.C.P.4 HUMORAL AND CELLULAR IMMUNE RESPONSE TO RECOMBINANT HIV-HEPATITIS B SURFACE ANTIGEN PARTICLES.

Michel, M.L.*; Maryline Mancini*; Vogt, G.***; Hennin, Y.**; Rivière, Y.**; Dormont, D.*** and Tiollais, P.*.
*Unité de Recombinaison et Expression Génétique (INSERM U.163, CNRS UA 271), Institut Pasteur, 28 rue du Docteur Roux - 75724 Paris Cédex 15, **Unité d'Oncologie Virale, Institut Pasteur, 28 rue du Docteur Roux - 75724 Paris Cédex 15, ***Commissariat à l'Energie Atomique, Fontenay aux Roses, France.

Objective. To evaluate the immunogenicity of HBsAg particles carrying HIV1 envelope determinants.
Methods. Rhesus macaques were immunized with recombinant HIV-HBsAg particles purified from transfected mammalian cells.
Serum from vaccinated animals was evaluated for antigenic potency and for the ability to neutralize HIV1 infectivity in vitro.
Peripheral blood lymphocytes were tested for their ability to proliferate in response to stimulation with purified, non disrupted HIV1.
Results. Using a HBsAg particle carrying a fragment of HIV gp120 enveloppe protein (AA384-472) comprising the CD4 binding site, we obtained neutralizing antibody against HIV1 and a T cell response against both parts of the fusion protein (HBsAg and HIV).
Conclusion. HBsAg particles seem to be a good carrier for the presentation of HIV epitopes and enable us to induce in vaccinated macaques neutralizing antibodies and an helper T cell response against a functional domain of gp120 envelope protein.

M.C.P.5 PRODUCTION AND CHARACTERIZATION OF A HUMAN-MOUSE CHIMERIC MONOCLONAL ANTIBODY (Cβ1) AGAINST HIV

Matsushita, Shuzo*; Maeda, H.**; Maeda, Y.*; Tokiyoshi, S.**; Hattori, T.* and Takatuski, K.* et al. *The Second Division of Internal Medicine, Kumamoto University Medical School, Kumamoto, Japan. **Chemo-Sero-Therapeutic Research Institute, Kumamoto, Japan.

Objective. To determine the anti-HIV functions of a human-mouse chimeric monoclonal antibody(Cβ1) in vitro.
Methods. A murine hybridoma (54'CB1) cells which produced a type specific neutralizing monoclonal antibody (0.5β) were used to produce human-mouse chimeric antibody. Both V_H and V_k genes were cloned from 54'CB1 cells and linked to human Cr1 and C_k genes respectively. These chimeric genes were transfected with P3-X63 cells. After appropriate selection chimeric antibody producing clone (Cβ1) was obtained. Chimeric Cβ1 antibody was purified from culture supernatant by staphylococcal Protein A-Sepharose.
Results. The binding and neutralizing activities of Cβ1 antibodies were similar to those detected with 0.5β. No antibody dependent enhancement of HIV-infection was detected with 0.5β and Cβ1 when U937 cells were used as target cells in an HIV infection assay. Complement dependent cytolysis of HIV-infected cells and antibody dependent cellular cytotoxicity against HIV-infected cells were observed in the presence of chimeric Cβ1. By contrast, murine 0.5β failed to mediate these activities.
Conclusion. These results may facilitate the use of human-mouse chimeric monoclonal antibodies against HIV-infections.

M.C.P.6 MAPPING THE NEUTRALIZING EPITOPE OF HIV-1 ENVELOPE PROTEIN

Javaherian, Kashi*; Ross, K.*; Profy, A.*; Langlois, A.**; Matthews, T.**; Putney, S.* et al.
*Repligen Corporation, Cambridge, MA, USA, **Duke University Medical School, Durham, NC, USA.

Objective.We showed previously that the principal neutralizing domain of HIV-1 envelope protein of IIIB isolate represented by a 24 amino acid peptide called RP135 is located within a disulfide loop (amino acids 296-331) We have attempted to locate the neutralizing epitope more precisely inside the loop.
Methods. A series of small peptides corresponding to different parts of the loop were synthesized. Sera were raised against these peptides and each was tested for fusion inhibition and neutralization activities.
Results. Only peptides related to the "tip" of the loop containing the sequence glycine-proline-glycine were capable of raising neutralizing antibodies. We show peptides of the size of 8-10 amino acids are sufficient in size to elicit neutralizing activities. We have also raised antibodies against a hybrid peptide of 15 amino acids which was shown to neutralize two viral isolates.
Conclusion. Sera raised against small peptides (8-10 amino acids) corresponding to the tip of the principal neutralizing domain of gp160 are capable of neutralizing the virus.

M.C.P.7 *IN VIVO* IMMUNISATION AGAINST HIV PROTEINS USING GAG SYNTHETIC PEPTIDES: PRELIMINARY RESULTS.

Vaslin, Bruno *,**; Claverie, J.M.**; Barre-Sinoussi, F.C.**; Kourilsky, P.** and Dormont, D.*,**.
* CRSSA-CEA (DPS/SPE), Fontenay-aux-Roses, France; ** Institut Pasteur, Paris, France.

Objectives. As T immunogenic peptides have been shown to be constituted of rare Self motives, we tried to boost the immune response to HIV 1 proteins with five of them, located in conserved regions of HIV's GAG polyprotein.
Methods. Five GAG synthetic peptides, selected for their absence in Self-protein sequence data bank, and which are conserved among 13 HIV isolates, have been inoculated into three animal species (Mouse, Rabbit, Baboons). The animals received two subcutaneous injections of glutaraldehyde polymerised peptides: the first was performed in complete Freund adjuvant emulsion, and the second in a calcium phosphate precipitate. They were then challenged with heat inactivated HIV 1 protein (LAV 1 isolate) by footpad injection in mice or IV in Baboons and Rabbits. Clinical and immunological responses (western blot), were followed and compared to those of controls, which had only received HIV proteins injection.
Results. Monkeys presented febrile, and long lasting lymphadenopathies begining 21 days after the challenge, but no antibodies to HIV 1 proteins were detected by western blot analysis. Although rabbits did not show any clinical or serological signs, mice developped ulceronecrotic lesions on back, at site of peptides inoculation, wich was different than the HIV proteins injection locus. Controls behave with no abnormal clinical symptoms.
Conclusions. Four of these peptides have been reported elsewhere to be recognize in vitro by HLA A-2 restricted T cytotoxic cell line specific for HIV. Considering the pathology observed we then speculate on the activation of T cell population in this protocol. If the necrotic ulcerations established in this ten mice lot are reproductible, mice could provide a model for T epitope screening, on the assumption that they do stimulate T cell populations. These peptides could then be used as immune response boosters in vaccine developpment toward AIDS.

M.C.P.8 HIV-1 RECOMBINANT gp160 VACCINE RECIPIENTS DEMONSTRATE gp160-SPECIFIC LYMPHOCYTE PROLIFERATION PRIOR TO WESTERN BLOT REACTIVITY.

Keefer, Michael C., Bonnez, W., Roberts, N.J.,Jr., Dolin, R., Reichman, R.C.
University of Rochester School of Medicine, Rochester, NY USA

Objective. To characterize cellular responses to HIV rGP160 vaccine.
Methods. As part of the NIAID multicentered AIDS vaccine evaluation program, we enrolled 12 volunteers in a phase 1 randomized, double-blind, placebo-controlled trial of baculovirus-expressed recombinant HIV-1 envelope glycoprotein gp160 (rGP160; MicroGene Sys). Six subjects received rGP160, 3 Hep-B vaccine, and 3 placebo at 0, 1, and 6 months. We performed lymphocyte proliferation assays (LPA) using cryopreserved peripheral blood mononuclear leukocytes obtained at day 56 (28 days post first booster). The rGP160 and a control consisting primarily of the major contaminating baculovirus glycoprotein were used as antigens.
Results. Background baculovirus proliferation was eliminated in 11/12 subjects at a concentration of 0.1 mcg/ml in dose response assays. Higher antigen concentrations produced generalized stimulation and did not distinguish the vaccine recipients from controls. At 0.1 mcg/ml, all 6 rGP160 recipients had stimulation indices (SI)>2.5 (5/6 had SI >3.5). The SI was <2.0 in all 6 subjects who did not receive rGP160. Western blot (WB) assays were performed on day 56 sera and were positive for only one GP160 recipient at that time. Sequential LPA on this subject disclosed: SI=1.0 prior to vaccination, SI=4.8 at day 28 (immediately pre-booster and two weeks prior to initial positive WB), and SI=15.9 three months post-first booster. The other 5 rGP160 recipients also developed WB reactivity 2-4 months after demonstrated reactivity in LPA.
Conclusion. The HIV-1 rGP160 vaccine induces cellular immune recognition, as illustrated by lymphocyte proliferation, prior to detection of antibodies by Western blot.

M.C.P.9 USE OF POLYMERASE CHAIN REACTION FOR DIRECT DETECTION OF HIV-1 IN CLINICAL SAMPLES

Mark Marak, G. Keller, D.P. Huang, M. Fisher and D. Petersen.
Biotech Research Laboratories, Rockville, MD 20850 USA

Objectives: The Polymerase Chain Reaction assay was used for the direct detection of HIV-1 nucleic acid sequences in peripheral blood lymphocytes (PBL's) from high risk male homosexuals, blood donors who tested positive for HIV-1 by ELISA, babies born to HIV seropositive mothers, and from normal control individuals.
Methods: The DNA was extracted and HIV-1 specific sequences were amplified by PCR using specific primers for the gag and env regions. Control amplifications were performed using primers for ß-globin. All samples were tested by ELISA and Western Blot assays. Some samples were also tested by co-cultivation with PHA stimulated PBL's from normal donors.
Results: All culture positive samples tested (about 40 patient samples) were also PCR positive. However, 10 out of 31 high risk individuals who were antibody and culture negative were positive by PCR. Six of these 10 individuals subsequently seroconverted to HIV-1. Almost all (340/343) antibody positive adult individuals tested were also PCR positive. Three samples, however, (all of which belonged to the high risk male homosexuals group) were repeatedly negative or only borderline positive by PCR for both gag and env. All babies born to seropositive mothers were HIV-1 antibody positive, presumably due to the presence of maternal antibody. Approximately 60% (56/94) of these babies were PCR positive, while the rest were negative. All 67 normal donors tested were negative by PCR.
Conclusion: PCR provides an extremely sensitive test for the direct examination of HIV-1 in PBLs. This assay is capable of detecting HIV infection in high risk individuals, even before they seroconvert, and of confirming Western Blot indeterminate samples. In addition, PCR may be a useful tool for examining babies born to seropositive mothers, where the presence of antibody does not necessarily imply infection. The PCR method is much faster, cheaper and far more sensitive than cocultivation for the direct detection of HIV in clinical samples.

M.C.P.10 GP160 ISCOMS: A CANDIDATE HIV VACCINE.

Akerblom,L.*, Villacres,M.*, Lundin,K.**, Ljunggren,K.**, and Morein,B*. *Biomedical Center, BOX 585, S-75123 Uppsala,Sweden. **Karolinska Institute, Box 60400, S-10401,Stockholm, SWEDEN

Objective. To formulate a candidate HIV vaccine for the prevention of AIDS.
Methods. Iscoms were formed using gp160 (vaccinia) and gp160 (baculo) according to Morein et al. (1984).Immune response was analyzed in an indirect ELISA using defined recombinant technology products and peptide as antigens. These antigens were gp160 (vaccinia), PB1 (part of gp120) and RP 135 (a synthetic peptide).Neutralization test was done according to Nara et al.(1987). ADCC was done according to Ljunggren et al. (1987) CD4 binding essay was done according to Lundin et al.(1987).
Results. Iscoms containing gp160 from HIV, elicited high antibody titers in mice, rabbits and guinea pigs after two immunizations. The animal sera were tested for syncytial inhibition, ADCC activity and for CD4 blocking capacity. All sera were negative in ADCC. Blocking of gp120 binding to CD4 positive Jurkat cells was shown by mouse sera at a range of serum dilutions of 1/50 to 1/1250. Syncytial inhibition titers against the homologues isolate IIIB were in the order of 1/4 to 1/128 and cross neutralization titers were in the range of 1/4 to 1/16 using the heterologues isolate RF.
Conclution. The gp160 iscoms gave rise to high antibody titers in mice, rabbits and guinea pigs. These iscoms elicited neutralizing antibodies in mice towards the homologues isolate IIIB as well as for the distantly related HIV isolate RF indicating the possibility of inducing group specific neutralization.

M.C.P.11 CLINICAL AND VIROLOGIC RESPONSES TO A RECOMBINANT VACCINIA HIV-1 GP160 VACCINE (HIVAC-1e)

Collier, Ann*; Hu, S-L**; Coombs, R*; Arditi, D*; Corey, L*.
*University of Washington and **Oncogen Corp., Seattle, WA, USA.

Objective. To describe and compare the clinical and virologic responses of healthy HIV-negative men after receipt of recombinant HIV-1 gp160 vaccine (HIVAC-1e) and vaccinia(V) vaccines.
Methods. 29 men (age 24-46) with history of V immunization (25>10 years ago) were randomized to receive HIVAC-1e or V (ful) by intradermal scarification in initial(I) doses of 10^7 (low,L), 10^8(medium, M), or 10^9(high,H) pfu/ml with a booster(B) of M or H 8 weeks later; 1 V naive man got HIVAC-1e at 10^7(I) and a L B 8 weeks later.
Results. HIVAC-1e or V virus was isolated from the I vaccination site in 1/1 V-naive, and 5/10, 9/10 and 9/9 L, M, and H dose subjects. In M and H recipients, mean duration of I shedding was 6.3 days for HIVAC-1e and 4.7 days for V(P=NS). After B, 8(50%) of HIVAC-1e and 6(43%) of V recipients shed virus from the site for 1.0 and 0.8 days, respectively(P<0.01 for I vs B). Restriction enzyme analysis of 1st and last day HIVAC-1e lesion isolates from 2 subjects showed them to be identical to the vaccine strain. 26 of the 29 persons with a history of previous V had V neutralizing antibody titers at enrollment. The baseline GMT for HIVAC-1e recipients was 38.2 and rose to 121 after I and 108 after B. For V recipients, the respective GMT's were 32, 82.4 and 82.5. 61% of subjects had a 4-fold rise in V neutralizing titer after I dose vs 0 after the B. V seronegatives shed virus longer than V seropositives. No toxicity was seen with either vaccine. Ab to HIV envelope(env) proteins were detected in 3/16 HIVAC-1e recipients; 2 V-seronegatives and 1 V-seropositive developed Ab to gp41 and gp120. Three of 4 HIVAC-1e subjects who shed virus for >14 days developed HIV env Ab compared to 0/12 who shed for <14 days.
Conclusion. This trial demonstrates the safety and genetic stability of this HIV-1 gp160 vaccinia recombinant vaccine. The clinical and virologic responses to vaccination were similar between HIVAC-1e and V. The development of env Ab appears related to the duration of HIVAC-1e replication in skin; which is inversely related to the presence of pre-existing V neutralizing antibodies. The lack of local viral replication after B suggests that other forms of subunit vaccines should be evaluated for boosting.

M.C.P.12 KINETICS, MAGNITUDE AND DURATION OF ANTIBODY RESPONSES IN HIV-1 RGP160 VACCINEES.

*Gorrison, Leslie; *Midthun, K.; *Clayman, B.; **Smith, G.; *Viscidi, R.; and the NIAID AIDS Vaccine Evaluation Group. *Johns Hopkins University, Baltimore, Maryland USA; **MicroGeneSys, Inc., West Haven, Connecticut, USA.

Objective. To characterize the kinetics, magnitude and duration of serum antibody responses of healthy adults participating in a multicentered phase 1 safety and immunogenicity trial of baculovirus expressed gp160 (rgp160) of HIV-1 (VaxSyn HIV-1 MicroGeneSys, Inc.).
Methods. 33 HIV seronegative voluneers were vaccinated at 0, 1 and 6 months with 40 or 80 ug rgp160 (N=24) or a control preparation (N=9). Coded blood specimens obtained from volunteers before and at 0.5, 1, 1.5, 2, 4, 6, 6.5, 7 and 9 months after vaccination were tested for IgG antibody responses by Biotech/Dupont Western blot (WB), Abbott HIV EIA, and noncompetitive solid phase enzyme immunoassay (EIA) using rgp160 as antigen. The specificity of rgp160 EIA was confirmed by a blocking assay.
Results. The rgp160 EIA was the most sensitive assay for detecting serum antibody responses in rgp160 vaccinees. Of 23 vaccinees with antibody responses by any assay, 96% were detected by rgp160 EIA, 91% by WB, and 39% by Abbott HIV EIA. The agreement between the rgp160 EIA and WB results was 91% compared to 58% for the rgp160 EIA and Abbott HIV EIA. The specificity of the tests was 100% each for the rgp 160 EIA and WB and 90% for Abbott HIV EIA.

The kinetics and magnitude of antibody responses in sera of vaccinees were characterized by the rgp160 EIA. Of the 22 vaccinees detected by rgp160 EIA, 17% had a significant rise in antibody titer after the first, 73% after the second, and 100% after the third vaccination. After the second and third vaccinations, the level of antibody increased 3.6-fold and 6.3-fold above the prevaccination level. By 9 months after the initial vaccination (3 months after the third dose), the level of antibody had declined but remained elevated above prevaccination levels.
Conclusion. The rgp160 EIA was more sensitive than the WB or Abbott HIV EIA, and detected serum IgG antibody responses to rgp160 in 22 of 24 vaccinees. This EIA made it possible to quantitate the magnitude of anamnestic responses to the second and third doses of vaccine and to determine the duration of responses over the 9-month period after vaccination.

M.C.P.13 EVALUATION OF A SYNTHETIC HIV-1 P-17-BASED CANDIDATE AIDS VACCINE, HGP-30

Allan L. Goldstein*, Paul H. Naylor*, J. E. Kirkley*, C. W. Naylor*, C. J. Gibbs**, and P.S. Sarin**, *The George Washington University Medical Center, Washington, D.C., National Institutes of Health, Bethesda, MD, U.S.A.

Objective: To evaluate the safety, immunogenicity and efficacy of a synthetic subunit vaccine based on an HIV p17 peptide analogue (HGP-30)
Methods: The synthetic peptide HGP-30 (Naylor et al, PNAS, 84, 2951, 1987) was conjugated to keyhole limpet hemocyanin (KLH) and injected with various adjuvants at different doses in a variety of animal species. The presence of antibodies were detected by ELISA (HGP-30 specific) and Western blot (p17 specific). Neutralization activity was evaluated as inhibition of in vitro virus replication and/or virus induced syncial formation with different HIV-1 strain.
Results: Immunization of animals with HGP-30-KLH gave antibodies to HGP-30 as detected by ELISA, to p17 by Western blot and which on challenge with whole or disrupted virus enhanced the production of antibodies to p17. High titer antibodies for p17 effectively neutralized various strains of HIV in in vitro assays. Similar results were obtained with monoclonal antibodies which recognize HGP-30. The proposed candidate subunit vaccine, has proven safe in a number of animals species including chimpanzees.
Conclusion: A synthetic subunit vaccine based on HGP-30 representing immuno dominant epitope of HIV-p17, produces antibodies in animals which recognize HIV p17, neutralize HIV infection in vitro and prime the animal to respond to native HIV p17. Based on these studies a phase-1 clinical trial will soon be initiated in England.

M.C.P.14 CELLULAR IMMUNITY IN HIV-1 RGP160 VACCINEES.

Midthun, Karen*; Garrison, L*; Gershman, K*; Clements, ML*; Smith, G.**; and Adler, W.***. *Johns Hopkins University, Baltimore, MD., U.S.A., **MicroGeneSys, Inc., West Haven, CT., U.S.A., ***NIA, NIH, Baltimore, MD., U.S.A.

Objective. To evaluate cell mediated immune responses in healthy adults who participated in a phase I safety and immunogenicity trial of recombinant gp160 (rgp160) of HIV-1 (VaxSyn HIV-1, MicroGeneSys, Inc.).
Methods. Twelve volunteers at low risk and without evidence of HIV-1 infection were vaccinated at 0, 1, and 6 months with one of the following: 40 ug rgp160 (N=3), 80 ug rgp160 (N=3), Recombivax HB (N=3), or placebo (N=3). All 6 rgp160 vaccinees had detectable antibody to gp120 or 160 by Western blot after the third vaccination. Blood drawn before and at 0.5, 1, 1.5, 2, 4, 6, 6.5, and 7 months after initial vaccination was tested by the following in vitro assays of cellular immune function: lymphocyte subset analysis, natural killer (NK) cell lytic activity, antibody dependent cellular cytotoxicity (ADCC), proliferative response of peripheral blood lymphocytes to rgp160 and to mitogens (PHA, CON A, PWM) and pokeweed mitogen-induced Ig synthesis. Responses of the rgp160 vaccine group were compared to those of the control group (recipients of Recombivax HB or placebo).
Results. The rgp160 group had higher absolute lymphocyte counts but there was no difference in the percent representation of lymphocyte subsets (CD3, CD4, CD8, CD19) between the two groups. Proliferative responses to all mitogens were normal but lower in the rgp160 group. Spontaneous Ig synthesis in vitro was not different between the groups while PWM induced IgG and IgM synthesis was higher in cells from the rgp160 group. Response to rgp160 in vitro showed that individuals from both groups could be stimulated into proliferative cycles although cells from some of the rgp160 vaccinees proliferated to a much greater degree. NK and ADCC activity were similar in the two groups.
Conclusion. The rgp160 vaccine, which induced specific antibody formation in vivo to gp120 or 160, appeared to have no adverse effects on CMI. Cells from the rgp160 vaccinees responded to rgp160 in vitro and to PWM activation in vitro to synthesize greater amounts of Ig. The rgp160 antigen caused a small degree of normal lymphocyte activation.

M.C.P.15 EXPRESSION OF RECOMBINANT PARTICLES WHICH DISPLAY AN HIV/P24 T-CELL EPITOPE FUSED TO THE HBV/HBc ANTIGEN

McGee, Juli S.*, Leturcq, D.*, Milich, D.**, Thornton, G.B.*, and Moriarty, A.M.*.
*R.W. Johnson Pharmaceutical Research Institute, La Jolla, CA, USA.
** Scripps Clinic and Research Foundation, La Jolla, CA, USA.

Objective: The importance of viral internal core or *gag* proteins in regulating the immune response to envelope epitopes has recently been demonstrated with hepatitis B virus (Milich *et al.*, *Nature*, 1987). Based on those studies we have sought to evaluate the role of the *gag* related antigens of HIV in the regulation of the immune response (T-dependent and T-independent) to themselves and to HIV gp120/160. In order to pursue these studies, we designed and expressed recombinant proteins expressing both HIV *gag* and HBc determinants.
Methods: A proposed T and B cell epitope from the C-terminus of the HIV/ P24 *gag* region (Coates *et al*, *Nature* 1987) was selected for insertion upstream from a recombinant clone expressing HBV core antigen in the form of particles. The HIV *gag* sequence was prepared as a synthetic oligonucleotide sequence and inserted upstream from the HBc sequence in the PstI-BamHI region of the multicloning site within the HBc construct.
Results: The recombinant fusion protein was expressed in *E. coli* and the antigenic specificity determined by ELISA assay and Western blot analysis. These analyses revealed a single protein species at 24,000 m.w., the size predicted for the P24/HBc fusion protein. This protein was reactive with anti-HBc and anti-P24 antibodies, generated in rabbits.
Conclusion: Recombinant vectors have been engineered capable of expressing a fusion protein which consists of HBc and HIV *gag* sequences. The fusion protein forms particles which, by electron microscopic examination, are similar to HBc particles. These HIV/HBV particles are being used to evaluate the role of *gag* T-cell determinants in the immune response to HIV.

M.C.P.16 RECOMBINANT VACCINIA VIRUSES THAT COEXPRESS HIV OR SIV ENV AND GAG-ENCODED PROTEINS PRODUCE RETROVIRAL PARTICLES

G. Mazzara*, Dennis Panicali*, N. Cormier*, R. Desrosiers**, J. MacKey**, N. King** et al. * Applied bioTechnology, Cambridge, MA and **New England Regional Primate Research Center, Southborough, MA, USA

Objective. To evaluate the formation of retroviral particles by vaccinia recombinants that express gag, env + gag, or env + gag + pol genes from HIV-1 or SIV.
Methods and results. The formation of free, defective, retroviral particles produced by monovalent and multivalent vaccinia recombinants that express HIV-1 or SIV polypeptides was assayed by several techniques, including electron microscopy and sucrose gradient centrifugation. We have demonstrated that vaccinia recombinants that coexpress env and gag genes give rise to the formation of enveloped retroviral particles that are secreted into the growth medium, while recombinants that express gag proteins alone yield immature, non-enveloped particles.
Conclusion. Recombinant vaccinia viruses that express one or more HIV-1 antigens have been proposed as candidate vaccines against AIDS. The production of enveloped retroviral particles by multivalent vaccinia recombinants suggests that they may have greater potential for eliciting an immune response effective against early events in HIV-1 infection.

M.C.P.17 TYPE-SPECIFIC NEUTRALIZING ANTIBODIES TO HIV-1 IN RABBITS IMMUNIZED WITH VACCINIA/HIV-1 RECOMBINANT VIRUSES

Hesselton, Ruthann*, Koup, R*, Panicali, D**, Mazzara, G.**, Day, E**, and Sullivan, J*. *University of Massachusetts Medical School, Worcester, Massachusetts, USA, **Applied bioTechnology, Cambridge, Massachusetts, USA.

Objective: To analyze humoral immune responses in rabbits immunized with vaccinia vectors expressing envelope genes from two strains of HIV-1.
Methods: NZW Rabbits were innoculated intravenously with $5x10^7$ pfu of vaccinia vectors which expressed either HIV-1 envelope genes (HTLV-III B or HTLV-III RF) or the gH gene of equine herpes virus as a control. Rabbits were boosted with $5x10^7$ pfu of the same vector 6 weeks after the initial innoculation. Antibody titers were determined by Western Blot analysis (HIV) or ELISA (Vaccinia). Neutralizing antibodies were determined using a syncytia inhibition assay with both III B and RF strains of HIV.
Results: All rabbits developed strong antibodies to both Vaccinia virus (titers to 1:409,600 by week 2) and to HIV-1 envelope antigens (titers to 1:10,240 by week 6). The major antibody response was to gp160 and gp120 with antibodies to gp41 appearing later and at lesser titers. Significant levels of neutralizing antibodies to HIV (≥1:64) developed by week 5 post innoculation. These neutralizing antibodies were type-specific and remained so even after boosting. Previous studies using vaccinia/HIV-1 env recombinant viruses in chimpanzees failed to elicit detectable neutralizing activity (Hu et al., Nature 328:721), though antibody responses in those studies were mainly directed to gp41.
Conclusion: Rabbits immunized with recombinant vaccinia/HIV-1 viruses develop significant type-specific neutralizing antibodies to HIV-1.

M.C.P.18 HYPERICIN: EFFICACY OF A NEW AGENT AGAINST HIV IN VITRO.

Valentine, Fred*, Meruelo, D.**, Itri, V.*, Lavie, G.**.
Departments of Medicine*, Pathology**, New York University Medical Center, New York, USA.

OBJECTIVE: To examine the effect of hypericin (HY), an aromatic polycyclic dione, against HIV in vitro.
METHODS: (a) Different concentrations of HY were incubated overnight with 1,000 to 10 tissue culture infective doses (TCID) of recent isolates of HIV-1 and phytohemagglutinin-stimulated normal human blood mononuclear cells (PHA-BMC), washed, cultured with interleukin 2 and monitored for the production of particulate reverse transcriptase (RT) or core antigen p24. In other expts: (b) PHA-BMC were infected first and then treated with HY for 2 hrs. and cultured, (c) PHA-BMC were pretreated with HY, washed, infected and monitored or (d) free HIV was exposed to HY, and examined for infectivity and particulate RT.
RESULTS: HY inhibited the production of HIV by PHA-BMC as assessed by RT and p24 when: a) HY and HIV were added together, b) cells were preinfected and then pulsed with HY, c) cells pretreated and then cultured with HIV in the absence of free HY, d) free HIV was incubated with HY for 2 hrs. and then added to PHA-BMC. This inhibition was most marked with 100 TCID or less, and at HY 10-60 μgm/ml, often resulted in complete inhibition of RT and p24 through 12 days of culture. These concentrations of HY do not inhibit antigen-stimulated proliferation of normal BMC.
CONCLUSION: Short exposures of cells or HIV to HY at nontoxic levels inhibit the formation of infectious HIV by mechanisms that are not yet clear. This data on HY and HIV, together with our observation that HY inhibits lethal retroviral infections in mice at levels nontoxic in vivo, indicates that HY should be developed as a potential anti-HIV agent for humans.

M.C.P.19

FUNCTIONAL ANTIBODY RESPONSE IN PERSONS IMMUNIZED WITH BACULOVIRUS-DERIVED GP160

Graham, Barney; Rowland, J.; Robinson, E.; Montefiori, D.; Mitchell, W.; Wright, P. and the NIAID Vaccine Evaluation Group. Vanderbilt University School of Medicine, Nashville, TN, USA.

Objective. To determine the functional serological response of vaccinees in the extramural NIAID sponsored trial of the MicroGeneSys baculovirus-derived gp160 candidate AIDS vaccine.
Methods. Neutralization (NT), complement-mediated antibody dependent enhancement (C'-ADE), and anti-fusion activity were measured in a cytopathic effect assay system based on neutral red uptake by viable MT2 target cells. NT is a measure of cell-free virus inactivation by serum; C'-ADE, done in parallel with the NT assay by adding complement to the system, measures the reduction in NT activity and is verified by detecting more rapid HIV replication, HIV specific protein synthesis, and syncytium formation; anti-fusion measures serum inhibition of cytopathic effect resulting from infected cell(H9/HTLV-IIIB)-to-target cell fusion in vitro. Volunteers were immunized on day 0, 30, and 180 with either 40 mcg or 80 mcg of gp160.
Results. Sera from all vaccinees at day 60 and sera from Vanderbilt vaccinees at days 210 and 270 had no evidence of NT, C'-ADE, or anti-fusion activity at any time point despite western blot positivity in many of the sera.
Conclusion. It is not known whether the inability to measure functional antibody activity in the sera of vaccinees is a function of the magnitude or quality of the antibody response.

M.C.P.20

HLA DR PEPTIDE INHIBITS HIV 1 INDUCED SYNCYTIA

Lewis, Dorothy[1,2]; Ulrich, R.[2]; Atassi, H.[3]; Atassi, M.Z.[2,3]
[1]Howard Hughes Medical Inst., and Depts. [2]Microbiol. and Immunol., and [3]Biochem., Baylor College of Medicine, Houston, TX 77030 USA.

The binding of human immunodeficiency virus (HIV) to CD4$^+$ cells might be enhanced if the envelope bound to several sites on the same molecule or to several different molecules. Because class II molecules are important in the presentation of antigens and bind both the T cell receptor (TCR) and CD4 molecules, we determined whether the HIV-1 envelope protein exhibited sequence similarity with DR molecules. Five regions with sequence similarity were found and examined for their ability to inhibit syncytia formation between H9/HIV cells and uninfected CD4$^+$ cells. Peptide 141-155 inhibited the release of ^{51}Cr from H9/HIV cells after addition of uninfected CD4$^+$ cells. The inhibition was seen at very high peptide concentrations (200μg/well) and achieved 60% levels. This peptide blocked the binding of monoclonal anti-CD4 (Leu3a) in one of 4 donors. This region, 254-268 in gp120, is highly conserved among HIV isolates and the region, 141-155, in the DR_β molecule is also highly conserved between haplotypes. Mutation of this region in HIV-1 has been previously associated with loss of infectivity (Willey et al, J. Virol. 62:139, 1988) and rabbit antibodies directed toward this region have neutralizing activity in vitro (Ho et al, Science 239:1021, 1988). Humans infected with HIV apparently fail to respond to this region in vivo. In addition, both mice and chimpanzees are unresponsive to this region when immunized with intact DR2. Immunization with the peptide, however, does induce a response. This region may, therefore, be essential in the design of an HIV-1 vaccine, but caution is suggested because of the possibility of induction of harmful anti-self DR responses.

M.C.P.21

RECOMBINANT ADENOVIRUS INDUCES ANTIBODY RESPONSE TO HIV gag IN MICE.

Rosenthal, Kenneth L.; Graham, F.L. and Prevec, L.
McMaster University, Hamilton, Ontario, Canada

Objective. Construction of recombinant adenovirus vectors capable of expressing individual human immunodeficiency virus (HIV) polypeptides in infected cells and their use to assess antigenicity and as potential vaccines.
Methods. Recombinant adenovirus vectors capable of expressing HIV gag (p55 and p24), and env (gp160) were constructed by inserting HIV structural genes into human adenovirus type 5 with or without foreign promoters. Expression of recombinant vectors was assessed using immunoprecipitation and western blotting. Mice were infected with these vectors and examined for the production of antibody and the generation of cytotoxic T lymphocytes (CTL) to HIV proteins.
Results. Recombinant adenovirus vectors expressed HIV gag in a variety of human cells including EBV-transformed human B cell lines. Infection of mice with Adgag resulted in the production of antibody to HIV gag. We are currently using these vectors to determine the role of individual HIV gene products in induction and serving as targets for both murine and human anti-viral CTL.
Conclusion. We have successfully constructed recombinant adenovirus vectors capable of expressing HIV gag and generating immune responses in mice.

M.C.P.22

HUMAN T-CELL CLONES DEFINE DISTINCT EPITOPES WITHIN THE V3 REGION OF HIV-1 GP120

Weinhold, Kent*; Stanley, D.*; Javaherian, K.**; Scott, C.**; Putney, S.** and Bolognesi, D.*. *Duke University Medical Center, Durham, NC, USA; **Repligen, Inc., Cambridge, MA, USA.

Objective. To identify epitopes within the HIV-1 envelope which are recognized by T-cells from seronegative individuals.
Methods. Peptides representing the V_3 region of HIV-1 gp120 were used to stimulate T-cell reactivity in primary cultures of peripheral blood mononuclear cells (PBMC) from seronegative donors. T-cell clones were derived, phenotyped, and examined for specificity against a panel of peptide constructs. Clones were analysed for cytolytic activity against autologous targets bearing peptide antigens.
Results. The HTLV-III$_B$ RP135 peptide was found to be a potent stimulator of primary T-cell reactivity in vitro whereas the HTLV-III$_{RF}$ analogue (RP139) was far less stimulatory and the HTLV-III$_{MN}$ peptide (RP142) lacked any detectable activity. Using hybrid peptides, the multiple CD4$^+$ T-cell clones were found to belong to 3 different specificity groups, each capable of recognizing a subdeterminant within the V_3 region of gp120. Representative clones from each of these groups had demonstrable cytolytic activity.
Conclusion. T-cells from HIV-1 seronegative donors recognize determinants within the V_3 region of gp120. Unlike the single epitope recognized by mice, human T-cells appear capable of distinguishing multiple sites. Lastly, the V_3 region of gp120 may be important not only for production of neutralizing antibodies, but also for eliciting virus-specific T-cell reactivity in potential vaccinees.

M.C.P.23

PLAQUE REDUCTION ASSAY TO DETECT HIV NEUTRALIZING ANTIBODIES IN SERA FROM HUMAN VACCINEES

Fenger, Terry W.*; Seaman, T.* and Belshe R.* and NIAID AIDS Vaccine Program **
*Marshall Univ. Sch. Med., Ht., WV., **Bethesda,Md. USA

Objective. To describe a neutralization (Nt) assay which employs vaccinia virus recombinant (VVR) infected CD4$^+$ HeLa cell monolayers.
Methods. HeLa cell monolayers + or - for HIV CD4 receptors were established in multi-well plates and upon reaching confluency (24 hrs) were infected at 100 PFU/10^6 cells with: 1) VVR expressing GP160 env protein, 2) VV,3) VVR or VV treated with sera from individuals vaccinated with recombinant GP160 (rGP160) vaccine (Microgenesys) and 4) VVR or VV treated with preimmune sera from vaccinees. Concomitantly sera were assayed for neutralizing antibodies using inhibition of syncytia formation induced by HIV strain IIIB in MOLT 3 cells.
Results. Infection with VVR but not VV produced plaques by day 3 in CD4$^+$ HeLa cell monolayers but not in CD4$^-$ cell monolayers. Plaques resulted from syncytia formation and subsequent sloughing of balooned cells. HIV membrane antigens were demonstrated on the surface of cells at the periphery of plaques by immunofluorescence. In both assays sera from vaccinees inoculated with 3 80ug doses of rGP160 did not exhibit neutralizing activity, in spite of the fact that post vaccine sera exhibited positive ELISA and reactivity to GP160 using Western blots.
Conclusion. A plaque assay employing VVR and CD4$^+$ HeLa cells has been used to examine sera for neutralizing antibodies among rGP160 vaccinees.

M.C.P.24

QUANTITATIVE ASSESSMENT OF SERA INHIBITION OF HIV/RECEPTOR BINDING

Janis V. Giorgi; Nishanian, P.G.; Ho, D.H. and Schmid I.
UCLA School of Medicine and the Jonsson Comprehensive Cancer Center, Los Angeles, CA, USA

Objective. Vaccination against HIV is expected to induce antibodies with a variety of biological activities. Antibodies that inhibit HIV/receptor binding, as well as those that neutralize infectivity, are expected to be protective. Our goal was to develop a sensitive assay to assess sera inhibition of HIV/receptor binding.
Methods. Using an EPICS C flow cytometer (EPICS Division of Coulter Electronics, Hialeah, FL), we first established the relative fluorescence intensity of each of the 256 channels of the 3-decade log scale of our instrument. Using beta-propiolactone inactivated HIV (Nishanian, et al., J. Immunological Methods 107:261, 1988), virus binding to T-cells was detected using an anti-HIV serum and FITC-goat anti-human Ig.
Results. When antibodies to gp120 were incubated with the HIV prior to adding the HIV to the T-cells, inhibition of HIV binding was observed with some sera, while enhancement of HIV binding was observed with other. This activity could be precisely quantitated, permitting accurate assessment of minor differences in the biological properties of different sera.
Conclusion. This method will be valuable for assessing the immune response of vaccinated persons, and is being used to map the epitopes of the virus that are involved in binding (see abstract by David Ho, et al., this Conference).

M.C.P.25 CROSS REACTIVITY OF GOAT SERA GENERATED AGAINST FIVE HIV-DERIVED GP 120 RECOMBINANTS AND SYNTHETIC PEPTIDES

Yair Devash*, Kashi Jahavarian, Albert T. Profy, and James Rusche
Repligen Corp., Cambridge, MA 02137, USA
Present Address: E. I. Du Pont Co., Diagnostics Division, Glasgow, DE 19810, USA

Objective: To determine the binding specificity of goat sera generated against C-terminal fragment of gp 120 (PB-1) and amino acid 301-324 loop sequences derived from five HIV isolates (3B, RF, MN, WMJ2, and SC).

Methods: Three different Elisa formats (peptide antisera/peptide antigens, peptide antisera/PB antigens, and PB-1 antisera/PB-1 antigens) were utilized to determine the cross reactivity patterns of the sera with the antigens.

Results: Antisera generated against MN and SC were highly cross reactive. This cross reactivity pattern was retained regardless of the antigen and antisera used and could not be predicted from the amino acid seqences of the five variants. Furthermore, it was established that the PB-1 fusion domains and the peptide KLH-carrier protein were not contributing to the cross reactivity.

Conclusion: The study demonstrates a strong cross reactivity of MN and SC. The cross reactivity could not be predicted from the linear sequences of the five peptides and the five PB-1's. Correlation of this cross reactivity with that of HIV-infected human sera and virus neutralization is discussed.

M.C.P.27 SIV VACCINE DEVELOPMENT SURVEILLANCE

Schultz, A. M. and Glass, M.

Vaccine Research and Development Branch, AIDS Program, NIAID,
National Institutes of Health, Bethesda, MD, USA 20892

Use of macaques infected with SIV has become an important disease model for the development of a vaccine for human AIDS. A proliferating variety of approaches (synthetic peptides, recombinant peptide regions, subunit approaches, live expression vectors with different gene products, killed and live attenuated SIV) are under development and being utilized by numerous groups, all destined for evaluation of safety and immunogenicity in the animal and, ultimately, for protection from SIV challenge. To further complicate the picture, immunologically distinct isolates of SIV are being used, some biologically cloned, some genomically cloned, and others uncloned. Some projects are in early stages, while others are well underway. As an aid to information dissemination, facilitation and coordination of these efforts, the Vaccine Branch of the NIAID AIDS Program maintains surveillance of initiation and overall progress in these experiments. A summary of research approaches and findings will be presented.

M.C.P.29 COMPARISON OF IMMUNE RESPONSES IN MICE IMMUNIZED WITH NATIVE HIV-2 ENVELOPE GLYCOPROTEIN OR CORRESPONDING IMMUNOSOME

Lise Thibodeau*, L. Flamand*, D. Oth*, L. Lachapelle*, and L. Montagnier**,
*Institut Armand-Frappier, Montréal, P.Q., Canada, **Institut Pasteur, Paris, France.

Objective Investigate the role of HIV antigen presentation on the first step of immune reaction (macrophages mobilization) as well as on later events such as T-lymphocytes proliferation and antibody synthesis.

Methods HIV-2-Immunosomes (HIV-2-IMS) were prepared by anchoring purified envelope glycoprotein into the phospholipidic bilayer of liposomes. The immune responses to HIV-2 purified gp140/125, or corresponding Immunosome, have been determined by the level of Interleukin I (IL-1) production by adherent peritoneal exudate cells (PEC), T-lymphocyte proliferation upon in vitro restimulation with the immunizing antigen, and by antibody synthesis evaluated by ELISA, IFA, neutralization of cell-free viruses and syncytia formation inhibition.

Results Mice Immunized with HIV-2-IMS developed both higher antibody response and neutralizing titers against HIV-2 than mice immunized with equal amounts of envelope glycoprotein. Similarly, IL-1 production was higher in mice immunized with HIV-2-IMS. In addition, upon in vitro restimulation, enhanced IL-1 production was observed only in mice primed and restimulated with immunosomes. T-lymphocyte proliferation, determined by 3H TdR incorporation, followed the pattern of IL-1 production.

Conclusion These observations indicate that the physical presentation of an antigen may be critical not only for their uptake by macrophages, and simultaneous release of IL-1, but also for the subsequent events in the cascade of immune responses, suggesting the potential application of liposomes as carrier for purified HIV antigen in designing an AIDS vaccine.

M.C.P.26 IMMUNOGENICITY OF HIV *env* GLYCOPROTEINS IS DEPENDENT ON PROPERTIES OF THE GLYCOCONJUGATE

Hammar, Lena; Malm, K.; Eriksson, S.; Fridberger, T.; Åkerblom, L. and Morein, B.
Dept. Veterinary Virology, Biomedical Center, Uppsala, Sweden.

Objective. Recombinant glycoproteins derived from the HIV-*env* gene are under evaluation as antigens in vaccines against AIDS. The importance of the structure and size of the glycoconjugate for eliciting a protective immune response is obscure. As a first approach to elucidate this matter we present data on the immunogenicity in mice of two *env* glycoproteins, which have been modified by treatment with glycosidases.

Methods. Gp120 (A), purified from HIV-1^{IIIB} infected H9 cell culture medium (Pyle STW et al. AIDS Res 1987;3:387-400.) and gp 160v (B), expressed in Vero cells from the HIV-1^{IIIB} *env* gene in a vaccinia virus vector, were incorporated into ISCOMs and treated with 1) buffer (non-modified control), 2) neuraminidase, 3) endoglycosidase-H or 4) glycopeptidase-F. The 8 antigen preparations were analyzed by EM, SDS-PAGE and immunoblot and injected, at a dose of 1ug (animal group A1-A4, B1-B4) or 0.1ug (group b1-b4) into mice (10 animals per antigen and dose) at two occasions, 4 weeks apart. Blood was withdrawn from the tail veins at intervals up to 8 months after the first immunization and the serum individually analyzed by ELISA for titre against gp160v and several related peptides.

Results. The serological immune response to the non-modified and modified glycoproteins differ with respect to relative antibody titre, timing and type of ELISA. As a general the modified proteins gave raise to a lower total titre than the non-modified glycoprotein.

Conclusion. The carbohydrate moieties are important for defining antigenic epitopes. It remains to be shown wether this has bearing on protective epitopes.

M.C.P.28 ZAIRIAN HIV-1 VARIABLE AND HYPERVARIABLE ENVELOPE FRAGMENTS

Agius, Gérard ; Snart, R. ; Kolesnitchenko, V. ; Zagury, J.F. and Zagury D
Université Pierre et Marie Curie, Paris, France

Objective To compare the heterogeneity, in Zairian asymptomatic carriers and atypically seropositive individuals, of amplified DNA fragments from envelope and gag regions.

Methods and results. DNA extracted from periferal blood mononuclear cells has been used for PCR amplification of envelope and gag regions. We have found that the PCR, if carried out under condition designed to avoid non specific amplification, results in a large number of false negatives.

PCR results (asymptomatic carriers)

location	amplified sequence	Z1	Z2	Z3	Z4	Z5	Z6	Z7	Z8
env	8-368	+	-	+	-	+	+	-	+
env	682-1021	-	+	-	+	+	+	+	-
env	1760-2093	+	-	-	-	-	-	-	-
gag	1551-1665	+	-	+	+	+	+	+	-
gag	856-1046	+	-	-	+	-	-	-	-

A modified PCR technique, involving lower annealing temperatures, has successfully amplified fragments of these variable envelope regions. The DNA fragments have been purified and reamplified using the PCR technique and enough DNA obtained for direct sequencing/sequencing of cloned fragments. The results are important in relation to the development of envelope based vaccines.

M.C.P.30 AN IMMUNODOMINANT EPITOPE OF THE HIV GP 160 ENVELOPE GLYCOPROTEIN RECOGNIZED BY CLASS I, MHC IMMUNIZED HUMANS

Achour, Ammar*; Fossati, I.*; Margaritte, C*; Berzofsky, J.A.**,; Gallo, R.C*** and Zagury, D*

* Université P. et M. Curie, Paris, France, ** Metabolism Branch, NCI, Bethesda, USA
*** NCI, Bethesda, USA

Objective : A single peptide corresponding to residues 308-322 of Rattner et al (1) sequence accounted of the murine CTL activity (2) measured using stimulator cells expressing the entire gp160 protein. Because CTL may be important for preventing direct cell to cell transmission of HIV we investigated the epitope specificity of the anti HIV CTL in immunized humans.

Methods : Volunteers, primed by rV expressing gp160 protein received boosts constituted by gp160 determinants. These PBL were stimulated in vitro by irradiated autologous cells carrying gp160 signals in a mixed lymphocyte culture. Effector PBL were assayed for specific cell mediated cytotoxicity by chromium release test, using EBV transformed B cells initially infected with rV or pulsed with P18.

Results : Our results show that immunized populations are CTL responders. Our data found that the peptide P18 may represent a good antigenic signal for specific CTL recognition. Moreover, they respond to a single site represented by a 15 residue synthetic peptide of T cell epitope and are seen by CD 8 CTL in association with class I (MHC) molecule.

Conclusion . This epitope which occurs in a highly variable segment of the envelope protein may be immunodominant in humans and of clinical importance in vaccine development.

M.C.P.31 MAPPING OF T- AND B- CELL EPITOPES OF HIV-1 nef PROTEIN IN IMMUNIZED CHIMPANZEES.

Gluckman, Jean-Claude* ; Yagello, M.* ; Sabatier, J.M.** ; Guy, B.*** ; Girard, M.****; Bahraoui, E.** et al.
* Pitié-Salpêtrière Medical School, Paris ; ** CNRS UA1179 INSERM U172, Marseille ; *** Transgène SA, Strasbourg ; ****Pasteur Vaccins, Paris, France.

Objective. As an approach to vaccination, the immunogenicity and fine specificity of HIV-1 $p27^{nef}$ (p27) regulatory protein for T and B cells were assessed using synthetic peptides.
Methods. Chimpanzees were repeatedly immunized with soluble purified p27 produced in E. Coli, associated with other recombinant HIV-1 proteins (gp160, p18), and mixed with MDP as an adjuvant. Four animals had been previously inoculated with recombinant vaccinia expressing different HIV-1 proteins, 2 of them having thus received p27. Two were naive. PBL proliferative specific responses (PR) (^{3}H-Thymidine incorporation) and serum antibody reactivity (ELISA) were sequentially tested against p27 and a set of synthetic peptides spanning the entire nef sequence.
Results. Independently of previous immunizations, PR to p27 was strong and sustained in 1 animal (mean SI = 9.2), moderate in 2 (mean SI = 5.7 and 5.9), weak in 2 (mean SI = 2.7 and 3.1), and negative in 1 (mean = 1.7). Anti-p27 antibody titers ranged from 1 : 1600 to 1 : 6400 in the sera of the 3 animals whose lymphocytes had the strongest PR. The dominant epitope recognized by PBL of these chimpanzees was located in the C- terminal region of p27 when peptides were compared for their capacity to induce PR. In parallel, one of the 3 major linear epitopes recognized by the corresponding sera was located closely, indicating that the last 40 amino-acids of p27 comprise both major T- and B- cell epitopes.
Conclusion. Beside demonstrating that $p27^{nef}$ presents dominant epitopes recognized by T and B cells on its C- terminal region, these data provide a means to explore the pathophysiological value of the immune response to nef product, and its possible usefulness for vaccination purposes.

M.C.P.32 DEMOGRAPHIC CHARACTERISTICS AND FREQUENCY OF EXCLUSIONARY CRITERIA IN A POPULATION VOLUNTEERING FOR HIV IMMUNIZATION.

Westblom, T. Ulf*; Belshe, R.B.*; Gorse, G.J.*; Anderson, E.L.*; Berry, C.F.* and the NIAID AIDS Vaccine Program**.
*Marshall University, Huntington, WV, USA, **Bethesda, MD, USA.

Objective: To define the population volunteering for an AIDS vaccine study (rGP160 MicroGeneSys) and to determine the frequency of occurrence of exclusionary criteria in such a population.
Methods: 166 volunteers were interviewed and examined. Blood was collected for routine laboratory testing as well as T cell counts, HIV ELISA (EIA), Western Blot (WB) and p24 Ag.
Results: 85 males (mean age 22.2, range 18-42) and 81 females (mean age 23.9, range 17-50) volunteered. 130/166 (78%) were university students. Most had learned of the study from news media (55%) or friends/workplace (37%). The most common causes for exclusion were the presence of indeterminant WB (26.5%) or a change of mind after the initial interview (24%). Other causes were abnormal CBC and Diff (7.2%), elevated ALT (3.6%), +HBab (3.6%), abnormal UA (3.4%), recent STDs (3.0%), T4 <400 (1.9%), abnormal CXR (1.7%), recognized high risk behavior (1.7%), +RPR (1.2%), promiscuity (1.2%), failure to meet age criteria (1.2%), unable to be available for entire study (1.2%), abnormal physical exam (0.6%) and +p24 ag (0.6%). No volunteers had +EIA. 14.5% had more than one reason for exclusion.
Conclusion. Even in a community with low prevalence for HIV, a large majority of healthy heterosexual volunteers can be expected to be ineligible for enrollment in HIV vaccine trials. An average of 4.8 volunteers were screened for each of 12 vaccinees chosen.

M.C.P.33 AN AUTOMATED MICROTITER TEST SYSTEM FOR THE DETECTION OF HIV-1 AND HIV-2 NEUTRALIZING ANTIBODIES

Mellert, W.*, Kleinschmidt, A.**, and Erfle, Volker*
*GSF-Abteilung für Molekulare Zellpathologie, D-8042 Neuherberg, **Medizinische Poliklinik der Universität München, D-8000 München, West-Germany.

Objective. Establishment of a microassay for the measurement of HIV-neutralizing antibodies using monolayer cells.
Methods. Incubation of human fetal lung cells (clone LC5) with HIV-1 or HIV-2 in microtiter plates and demonstration of cytoplasmatic viral proteins after two to three days using the indirect immunoperoxidase staining (IP). Demonstration of neutralizing capacitiy of sera in an colony-reduction assay. Use of an automated workstation (BIOMEK 1000) for the performance of the neutralization assay.
Results. The incubation of LC5 cells with HIV results in the formation of IP-positive colonies two to three days after infection. The colonies can be counted very easily and their number correlates to the amount of infective units in the inoculum. Preincubation of HIV with neutralizing sera prior to infection results in a distinct reduction of colonies. In comparison to endpoint test systems, this assay is more sensitive and the neutralizing capacity of sera can easily be quantified (titer determination).
Conclusion. The use of monolayer cells in combination with IP represents a reliable and easily to quantify test system for the detection of HIV neutralizing antibodies, which can be completely automated. This test system is fast, very sensitive, requires minimal handling of infectious virus and is thus suitable for the screening of large numbers of sera.

M.C.P.34 NOVEL APPROACH TO PURIFICATION OF HIV p24PROTEIN BY CLEAVAGE FROM HYBRID Ty VIRUS-LIKE PARTICLES

Jacqueline E.M. Gilmour+; Burns, N.R.+; Kingsman+ S.M.; Kingsman, A.J.*+and Adams, S.E.+
+British Bio-technology Limited, Cowley, Oxford, U.K. *Department of Biochemistry, University of Oxford, Oxford, U.K.

Objective: To develop a rapid method of purifying a component of a fusion protein

Method and Results: The coding sequence for HIV-1 p24 was cloned into a Ty:VLP vector. The resulting fusion protein assembles inot virus-like particles due to the presence of the yeast Ty p1 protein. This is linked to p24 via the recognition sequence of the blood clotting factor Xa. The VLPs can be readily purified in milligram quantities. The p24 component can then be cleaved from the particles with activated factor Xa. A rapid method has been developed for the subsequent purification of p24 from the cleavage mixture. This technology has also been used for the purification of other proteins including HIV TAT and NEF.

Conclusion: A simple and effective method has been developed for the purification of the p24 component of a fusion protein. This is a generic method applicable potentially to any protein of interest.

M.C.P.35 HIV VACCINE DESIGN: EXPLOITATION OF Ty VIRUS-LIKE PARTICLES

Mark Richardson* ; Adams, S.E.*; Griffiths, J.M.*; Burns,N.* Senior, J.M.* and Kingsman, A.J.*+.
*British Bio-technology Limited, Cowley, Oxford, U.K. and +Departent of Biochemistry, University of Oxford, Oxford, U.K.

A protein encoded by the yeast retrotransposon Ty can be used as a carrier for recombinant antigens. HIV antigens (gp120, gp41, p24, p17, reverse transcriptase, TAT) have been incorporated into specialised expression vectors for high level production in yeast. These antigen coding sequences include those for complete proteins and selected regions.

All of the Ty-HIV fusion genes are transcribed and translated into fusion proteins that assemble into hybrid virus-like particles (VLPs). The formation of VLPs is conferred by the self-assembly properties of the Ty protein. The hybrid VLPs contain about 300 copies of the fusion protein and hence about 300 copies of the added antigen. The non-Ty component is presented on the outer surface of the particles and induces the production of HIV-specific antibodies.

The ability of various of these polyvalent antigens to induce virus neutralising antibodies and cellular responses is currently being evaluated in rodents and non-human primates.

M.C.P.36 RHESUS MONKEYS IMMUNIZED WITH RECOMBINANT VACCINIA VIRUSES CONTAINING HIV-1 ENVELOPE GENES DEVELOP ANTIBODIES REACTIVE WITH ENVELOPE OF DIVERGENT HIV-1 STRAINS.

Wittek, Alec*; Wells, M*; Hendry, RM*; Carrow, E*; Moss, B**; Quinnan, G*; et al. *LRR, DV, FDA Ctr. for Biologics Eval. & Research, and **LVD, NIAID, NIH, Bethesda, MD U.S.A.

Objective: To study HIV-1 specific antibody (Ab) responses in rhesus monkeys immunized with recombinant vaccinia viruses containing the gp160 envelope genes of HIV-1 strains IIIB or RF.
Methods: Groups of 4 rhesus (Rh) monkeys were immunized with either $2X10^{8}$ PFU of a TK- deletion mutant of vaccinia virus (VAC) or recombinant vaccinia virus containing the HIV-1 IIIB (VAC-IIIB) or HIV-1 RF (VAC-RF) gp160 envelope gene, at weeks 0 and 9. Sera were collected at three week intervals for measurement of HIV-1 envelope reactive Ab. Serological assays were performed by Western blotting (WB) 1:10 dilutions of sera against commercial HIV-1 (strain IIIB) strips, and by whole virus (IIIB) ELISA and recombinant HIV-1 (LAV) gp160 ELISA at serum dilutions of 1:5 to 1:40.
Results: All Rh showed primary but not secondary takes. Ab results were:

	IMMUNIZING VACCINE (RESPONDERS/VACCINATED)		
ASSAY & STRAIN OF ORIGIN	VAC	VAC-IIIB	VAC-RF
HIV-IIIB WB gp120/160	0/4	4/4	3/4
HIV-IIIB WB gp41	0/4	0/4	3/4
HIV-IIIB ELISA (GMT)	0/4	3/4 (20.0)	3/4 (25.2)
HIV-LAV r-gp160 ELISA (GMT)	0/4	4/4 (24.0)	3/4 (15.8)

Conclusion: VAC-IIIB or VAC-RF induced broadly reactive Ab to HIV env. Only VAC-RF induced Ab to gp41, suggesting greater expression of the complete gp160 by VAC-RF or the immunodominance of an HIV-RF gp41 peptide sequence. Testing for Ab at 1:100 would have failed to detect Rh seroconversion.

M.C.P.37

SALIVARY ANTIBODIES TO HIV ANTIGENS IN AN AIDS VACCINE TRIAL.

Archibald, David; Amrheim,C.; Sun, D.; Tacket, C.
University of Maryland at Baltimore. U.S.A.

The development of HIV-specific secretory antibodies may be a desirable outcome in individuals receiving an AIDS vaccine. We investigated parotid and whole saliva samples from 5 volunteers who received a recombinant HIV-1 envelope glycoprotein (rgp160) vaccine (MicroGeneSys) for the presence of HIV-specific antibodies. Ten healthy, adult` volunteers received intramuscularly either 3 doses of rgp160, hepatitis B vaccine, or a placebo preparation on days 0, 30, and 180. Individuals receiving the rgp160 received either 40 or 80 ug at each vaccination. Saliva samples were collected on ice from the volunteers on days 0, 28, 60, 120, 194, and 270. HIV-specific antibodies were assayed using immunoblots (Epitope, Inc.). Blots were incubated with the saliva samples, then with a biotinylated anti-human immunoglobulin antibody and finally with a streptavidin-biotin horseradish peroxidase complex. To date, all volunteers were negative for HIV antibodies by ELISA (Abbott) in their serum. By Western blotting, serum antibodies to HIV envelope were demonstrated in 2 individuals, one who received the low dose vaccine and one who received the high dose. We evidenced antibodies to gp160 in day 194 whole saliva collected from one of these individuals. Stimulated parotid saliva collected on this date and all others did not contain detectable HIV-specific antibodies. Mean total IgA levels of the volunteers with stimulated flow were 5.5 mg% ±3.1 and 3.0 mg% ±1.4 for whole and parotid saliva respectively, as detected by ELISA. The finding of HIV-specific antibodies in whole saliva following vaccination may indicate that development of secretory immunity is possible.

M.C.P.38

RETENTION OF PURIFIED HIV-1 GP120 BY ALHYDROGEL.

Bess, Julian W. Jr., Pyle, S. W., Drummond, J. E., and Arthur, L. O. Program Resources, Inc., NCI-Frederick Cancer Research Facility, Frederick, MD, USA.

Objective. The duration of the humoral immune response in chimpanzees vaccinated with HIV-1 gp120 formulated in Alhydrogel suggests that gp120/alhydrogel complexes may be short-lived in vivo. In order to explore this possibility, we determined the effect of serum on gp120/Alhydrogel complexes.

Method. Radiolabelled HIV-1 gp120 was adsorbed to Alhydrogel and the resulting complexes were separated from non-adsorbed gp120 by centrifugation. The gp120/Alhydrogel complexes were resuspended in distilled water and aliquots were added to normal human serum or distilled water. Retention of gp120 was determined by pelletting aliquots at various times and determining the amount of radioactivity in the pellets and supernatants.

Results. HIV-1 gp120 is readily adsorbed by Alhydrogel and is stable for long periods of time when resuspended in distilled water. However, once added to serum, approximately half of the complexes immediately dissociate, and less than 20 percent of the gp120 remains complexed after 24 hours.

Conclusion. HIV-1 gp120/Alhydrogel complexes in serum are short-lived, in vitro, and may explain the short-lived humoral responses in chimpanzees. Additional adjuvants need to be evaluated for use in HIV-1 gp120 AIDS vaccine experiments.

M.C.P.39

REPLICATION OF HIV UNDER SINGLE GROWTH CYCLE CONDITIONS: A MODEL FOR STUDYING THE EFFECT OF ANTIVIRAL DRUGS.

Dianzani Ferdinando, Antonelli G., Capobianchi M.R., Amicucci P., Di Marco P., Turriziani O. The Institute of Virology, University "La Sapienza", Rome, Italy.

Objective. To describe an experimental model of HIV infection for testing antiviral drugs. Methods. C8166 cells were infected with 5-10 $TCID_{50}$/cell and then seeded in the presence or absence of antiviral drugs. At various time points cultures were collected and intracellular or extracellular virus was back titrated in fresh C8166 cells by standard limiting dilution method (0.5 Log ratio, 4 replicates per dilution), scoring syncitia formation after 4 days. Results. A single growth cycle of HIV has been established showing that replication is completed in 20 hr and that at each time point, the titer of intracellular virus is 2 Logs higher than the extracellular one. This model allows us to determine directly the effect of antiviral drugs in terms of infectious virus yield reduction rather than of production of indirect parameters of viral growth (RT, p24), or c.p.e.. Conclusions. HIV replication is not as slow as previously established. Availability of a simple and dependable test to directly measure infectious virus may overcome uncertainities and ambiguities connected with indirect evaluation of viral growth by RT or p24 antigen determination. By using this model we have been able to show synergism between zidovudine and dideoxycytidine

M.C.P.40

INDUCTION OF ANTIBODY TO HIV-1 ENVELOPE PROTEINS BY p24 CORE T EPITOPES.

Coates, Anthony R.M.*; Sia, D.Y.*; Mascagni, P.**; Toth, G.K.**; Masheim, L.R.* and Gibbons, W.A.**
* The London Hospital Medical College, London, UK.
** The School of Pharmacy, London, UK.

Objective. To investigate the possible involvement of HIV-1 p24 T epitopes in helping the generation of antibody responses to viral envelope proteins.

Methods. Previously we have located 5 T epitope-containing regions in a synthetic 104 residue long peptide corresponding to the sequence of the C terminal half of HIV-1 p24. Groups of BALB/c mice were individually primed subcutaneously with 50 ug of each of these T epitope-containing peptides in Freund's incomplete adjuvant and boosted with 50 µg of a synthetic chimeric peptide. Chimeric molecules used were a 138 mer peptide consisting of the 104 residue peptide linked to an envelope peptide which has been described to contain at least one B epitope, and another 42 residue peptide containing a selected p24 T epitope linked to the same envelope sequence. Antisera were collected 12 days post challenge and examined for their reactivity against HIV protein using Western blotting.

Results. Antibody against envelope proteins was detected in mice primed with the 104 mer or individual T epitope-containing peptides and boosted with the 138 mer. Anti-envelope responses were also found in T epitope primed mice which were boosted with the 42 mer chimeric peptide containing the same T epitope.

Conclusion. It appears that some T epitopes of p24 core protein can regulate antibody responses to the envelope protein.

M.C.P.41

T CELL EPITOPES IN A CHEMICALLY SYNTHESIZED 104-MER CORE PROTEIN (p24) OF HUMAN IMMUNODEFICIENCY VIRUS (HIV-1)

Sia, Dwo Y.*;Mascagni,P.**;Toth,G.**;Gibbons,W.A.** and Coates,A.R.M.*
*Dept.Med.Microb.,London Hosp.Med.Coll.,Turner Street, London E1 2AD, U.K.
**School of Pharmacy, London, U.K.

Objective. To locate T cell epitopes of the terminal half of p24 of HIV-1.
Methods. A 104-mer peptide corresponding to the amino acid sequence of the C-terminal half of p24 of HIV-1 was synthesized using an automated ABI 430-A peptide synthesizer and t-BOC chemistry. The long peptide was used to generate murine peptide-specific T cell lines. The lines were then tested for their ability to proliferate to whole virus and native core proteins of HIV-1. A set of 14-23 mer peptides containing predicted T cell areas and a second set of 15 residue overlapping peptides were then individually tested to stimulate proliferation of the 104-mer specific T cell lines in order to locate the T epitopes. Peptides that induced in vitro proliferation of the lines were also tested to generate in vivo help in the production of antibody reactive to synthetic peptide, recombinant and natural core proteins.
Results.The murine 104-mer specific T cell lines were of the helper phenotype and proliferated to the antigen in a MHC-restricted manner. The lines also responded to the whole virus and native p55. Five T epitope containing regions were defined in the 104-mer. Murine antibodies raised against the T epitope containing peptides recognized the synthetic protein, recombinant core proteins and viral p55 of HIV-1.
Conclusion·The 104-mer peptide shares both T and B epitopes with viral core proteins and,is therefore suitable for studies in HIV proteins.

M.C.P.42

DIPYRIDAMOLE HAS ACTIVITY AGAINST HIV-1 AND POTENTIATES THE ANTIVIRAL EFFECTS OF AZT AND OTHER DIDEOXYNUCLEOSIDES IN MONOCYTE/MACROPHAGES

Szebeni, Janos*; Wahl, S.M.**; Popovic, M*; Wahl, L.M.**; Gartner, S.*; Fine, R.L.*; Skaleric, U.** and Weinstein, J.N.*
*National Cancer Institute, **National Institute of Dental Research, National Institutes of Health, Bethesda, Maryland, USA.

Objective. To report: 1) an inhibitory effect of dipyridamole (DPM) on HIV-1 replication in monocyte/macrophage (M/M) cultures, and 2) a potentiation by DPM of the anti-HIV effects of azidothymidine (AZT) and dideoxycytidine (ddC) in M/M.
Methods. M/M cultures were prepared from peripheral blood monocytes purified either by adherence to plastic or by centrifugal elutriation. The cells were infected with $HIV/HTLV\text{-}III_{Bal}$/1985, and p24 antigen production was measured at intervals by ELISA.
Results. The ID_{50} values of AZT and ddC decreased by at least 5-fold in the presence of 2-10 µM DPM. With 0.4-0.08 µM DPM, the ID_{50} of AZT appeared to decrease by about 2- to 3-fold. No toxicity of DPM for M/M was seen at concentrations < 10 - 20 µM, as assessed by cell counts and by the functional criterion of superoxide generation (with or without stimulation by PMA). DPM did not potentiate AZT toxicity for human bone marrow progenitor cells in a CFU_{GM} assay.
Conclusion. DPM is widely used in the treatment of cardiovascular diseases because of its platelet anti-aggregant and vasodilator activities. Since M/M are major reservoirs for HIV-1 *in vivo*, our findings suggest the possible utility of DPM in combination chemotherapy of HIV infections. However, clinical efficacy and safety cannot be predicted on the basis of *in vitro* studies such as these.

M.C.P.43 LOW RESPONSE RATES TO HEPATITIS B VACCINE IN INACTIVE DRUG-ADDICTS

Mariagrazia Rumi, R. Romeo, S. Sampietro, D. Mari, E. Tanzi, M. Colombo
Institute of Internal Medicine University of Milan Italy

Objective: to evaluate the immune response to vaccine against hepatitis B virus (HBV) in former drug users. Methods: fifty-five former drug-addicts (DA, median age 25 yrs) were vaccinated against HBV with a yeast recombinant HBV vaccine (Engerix B-SKF) at 0,1 and 6 months intervals. 17 patients (a) had no HBV markers, 15 (b) had anti-HBc only, 23 (c) had anti-HBc and anti-HBs less than 10 IU/l. 25 DA were symptomless anti-HIV carriers with 217-1766 cells (median 578) and 52% response rates to skin tests (Multitest-Merrieux). 11 staff members and 30 healthy controls, age matched with DA, with no HBV markers or anti-HIV were also vaccinated. Results: response rates to vaccination were as follows:

Patients		7th mo		12th mo		24th mo	
		No(%)	GMT*	No(%)	GMT*	No(%)	GMT*
DA	a	13 (76)	1125	11 (77)	253	3 (43)	667
	b	1 (7)	0	1 (7)	0	1 (17)	0
	c	16 (70)	116	10 (53)	107	5 (31)	77
Staff pers.		11 (100)	4077	9 (82)	1662	8 (89)	609
Controls		29 (97)	2526	28 (93)	1226	-	-

(*geometric mean titer)

Conclusions: DA poorly responded to vaccination. Significant covariates for non-responders were isolated anti-HBc ($p<0.001$), HBV-DNA ($p \leqslant 0.05$) and anergy to skin tests ($p \leqslant 0.02$), suggesting that hyporesponsiveness to hepatitis B vaccine in DA may be multifactorial.

M.C.P.45 STUDY DESIGN ISSUES IN SIV VACCINE TRIALS

Spriggs, DR*; Ellenberg, Susan S.**.
Vaccine Research and Development Branch*, Biostatistics Research Branch**, AIDS Program, NIAID, NIH, Bethesda, Maryland, USA

The development of the SIV model for HIV infection and disease has created many opportunities for evaluating vaccine strategies for AIDS. Indeed, several pilot studies have already been performed. The limited availability of primates, however, necessitates the development of efficient designs for SIV vaccine trials. The purpose of this presentation is to discuss the central decision points in the rational design of SIV vaccine trials, the implications of these choices, and the quantitative tools necessary to make appropriate choices in study design. Specific issues will include: (1) How to avoid missing a potentially promising result; (2) how to decide about the necessity for controls; and (3) how selecting appropriate endpoints can influence the quality and timeliness of data from these trials. These discussions will focus on the use of existing study designs for screening chemotherapeutic agents (particularly those that address the scarcity of experimental subjects) when deciding on the design of SIV vaccine trials. The goals of this presentation are to provide detailed analyses of study design issues for SIV vaccine trials and to suggest methods for increasing the efficiency, quality, and speed of these trials.

M.C.P.47 GENERATION AND ANALYSIS OF RECOMBINANT VACCINIA VIRUSES THAT EXPRESS SIV POLYPEPTIDES

V. Stallard*, Dennis Panicali*, A. Destree*, M.D. Daniel**, R. Desrosiers**, G. Mazzara *et al. *Applied bioTechnology, Cambridge, MA and **New England Regional Primate Research Center, Southborough, MA, USA

Objective. To generate and evaluate prototype recombinant vaccinia-based vaccines for the prevention of AIDS in a non-human primate model system based on simian immunodeficiency virus (SIV)

Methods and Results. Recombinant vaccinia viruses containing the env, gag, and pol genes of SIVmac251, in monovalent and multivalent conformations, were constructed by standard methods of *in vivo* recombination. The recombinant viruses were analyzed for expression of the inserted genes using a variety of assays. Each of the recombinants synthesized the expected, appropriately modified polypeptide products at levels reflective of the strength of the vaccinia promoters used to direct their expression. Mice were inoculated with each recombinant, and the immune responses to vaccinia virus and to SIV were measured by several assays, including ELISA, Western blot analysis, and neutralization assays. All of the recombinant viruses elicited antibody responses to the expressed SIV antigens as measured by Western blot analysis; the recombinants that expressed env or env + gag also elicited SIV neutralising responses. The latter recombinants are currently being evaluated in rhesus macaques.

M.C.P.44 IMMUNE RESPONSE OF RABBITS AND CHIMPANZEES TO INACTIVATED WHOLE VIRUS CONCENTRATES OF HIV-1

Gregersen, Jens-Peter*; Fultz, P.N.**; Lamp, J.F. Jr.***; and Hilfenhaus, J.*
*Behringwerke AG, Marburg, West-Germany, **Yerkes Reg. Primate Center, Atlanta, USA, ***Electro Nucleonics Inc., Silver Spring, MD, USA.

Objective: To assess the immune response directed against inactivated whole virus concentrates of HIV-1 designated for a challenge experiment in chimpanzees.

Methods: Concentrates of HIV-1/HTLV-III$_B$ were prepared by continuous flow Sucrose gradient centrifugation containing 10^8 TCID$_{50}$/ml and more than 10^{11} physical viral particles/ml. After formaldehyde inactivation these concentrates were combined with different adjuvants and used to immunize rabbits and chimpanzees.

Results: After three immunizations excellent humoral immune responses against all viral core antigens and moderate responses against env antigens were observed in rabbits along with neutralizing antibodies and delayed type hypersensitivity responses to env and core antigens. First results indicate that chimpanzees respond stronger to these viral antigens than rabbits do.

More detailed and latest results will be presented at the congress. Challenge experiments in chimpanzees are planned for the near future.

M.C.P.46 CLINDAMYCIN PLUS PRIMAQUINE IS EFFECTIVE FOR PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA IN RATS

Smith, James W.; Bartlett, M.S.; Durkin, M.M.; Glancy, T.P. and Queener, S.F. Indiana University School of Medicine, Indianapolis, Indiana, USA.

Objective. To evaluate the efficacy of the combination of clindamycin (CM) and primaquine (PQ) for prophylaxis of *Pneumocystis* (PC) pneumonia in rats.

Methods. Female Sprague Dawley rats weighing between 120 and 140 grams were given dexamethasone, 1.2 mg/L for 4 days prior to transtracheal inoculation with PC and continuously through 7 weeks of prophylaxis. CM was given either continuously in water 50 mg/kg/day or by gavage once per day at 225 mg/kg. PQ was given by gavage once or twice per week at a dose of 2.0 mg/kg. Untreated controls and controls receiving trimethoprim/sulfamethoxazole (TMP/SMX) 50/250 mg/kg/day in water were included.

Animals were evaluated for PC infection by determining numbers of PC in Giemsa or methenamine silver stained impression smears of lung and graded 0-5+ on a logarithmic scale. Some rats died of other infections and only those surviving to the end of the study were evaluated.

Results. The combination of CM in water plus PQ once or twice a week by gavage prevented development of PC pneumonia in rats such that the mean Giemsa score for treated rats was 1.3 as compared to a mean score for untreated of 4.2, CM alone of 3.7, PQ alone of 3.4 and TMP/SMX 1.0. The combinations of PQ by gavage plus CM by gavage were less effective (mean score 3.7) than those of CM in water plus PQ by gavage.

Conclusion. Previous studies in rats and early clinical trials have shown that CM/PQ is effective for therapy of PC pneumonia. CM/PQ is effective for prophylaxis of PC pneumonia in rats and clinical trials should be considered.

M.C.P.48 THE SEARCH FOR A CANDIDATE VACCINE AGAINST AIDS · PROGRESS REPORT III

Zagury, Daniel*; Picard, O**; Bernard, J***; Salaün, J.J.*; Lurhuma, Z.**; Gallo, R.C.*
*Université P. et M. Curie, Paris, France, **Hôpital Saint Antoine, Paris, France, ***Institut Jean Godinot, Reims, France, *I.N.R.B., Kinshasa, Zaïre, **Cliniques Universitaires, Kinshasa, Zaïre, *N.C.I., Besthesda

Objective : to prepare an immunizing protocol generating a group specific anamnestic immune reaction against HIV similar to the one obtained by the candidate vaccine prototype using for priming rVaccinia expressing HIV gp160 and boosting with fixed autologous cells initially infected with the rVaccinia.

Methods : Immunizing determinants from the HIV env gp 160 as major and gag and pol proteins as accessory antigens. Treatments were first selected by in vitro assays for cell mediated immunity, then tested in Cercos for safety and immune response prior to use in human volunteers. Each series of 4 - 6 human volunteers received a predetermined protocol.

Follow up : Immune reaction - Humoral response : (a) Elisa, Western-Blot, (b) neutralizing Ab tested in T_4 cells (c) protective, or enhancing Ab tested in monocyte /macrophage cells ; Cellular response : P.B.L. proliferative index and specific cell mediated cytotoxicity - In addition the integrity of the immune system is assayed by T_4/T_8 cell count and IL_2 production by blood mononuclear cells.

Results : protocols using gp 160 epitopes as immunizing reagents induced humoral or/and cellular immune responses. An appropriate candidate vaccine easy to handle and protective (not enhancing) is indeed required to set up a clinical trial in a large group of high risk individuals in order to evaluate the level of protection against AIDS.

Zagury D. et al : Immunization against AIDS in humans. Nature, 326, 249-250, 1987 - Zagury D. et al : A group specific anamnestic immune reaction against HIV-1 induced by a candidate vaccine against AIDS. Nature, 332, 728-731, 1988

M.C.P.49

Inhibition of de novo HIV infection in monocyte/macrophages by agents which block the binding of HIV-1 gp120 to CD4.

Perno, Carlo-Federico, Yarchoan, R., and Broder, S.
National Cancer Institute, Bethesda, MD, USA.

Objective. To evaluate the ability of OKT4A or recombinant soluble CD4 (rCD4) to inhibit HIV replication in cells of monocyte/macrophages (M/M) lineage. Methods. Peripheral blood M/M prepared by various separation techniques (in some cases cultivated in medium with 100 U/ml GM-CSF), and U937, a monocytoid line, were exposed to HIV-1 (monocytotropic strain $HTLV-III_{Ba-L}$ or $HTLV-III_{B}$) in the presence or absence of OKT4A or rCD4 (provided by Genentech). Results. Fresh M/M had relatively low amount of surface CD4 (10-35% weakly CD4+ by FACS). In most cases the amount of CD4 increased as the cells were permitted to mature for 5 days (55% CD+). U937 cells were >98% CD4+. Despite these differences among M/M populations, OKT4A inhibited HIV replication in all M/M by >98% for up to 30 days after viral challenge, even at the lowest concentration tested (0.06 ug/ml). rCD4 at 5 ug/ml inhibited HIV replication in all M/M populations by >98%. Also, 1 ug/ml rCD4 inhibited HIV by 75% in mature M/M and in GM-CSF-exposed M/M, while somewhat less inhibition was achieved in fresh M/M. $HTLV-III_{B}$ replication was >98% inhibited in U937 by 0.1 ug/ml rCD4 and 1 ug/ml OKT4A. No consistent HIV suppression was found with OKT4C (a monoclonal antibody directed to a different epitope on CD4) or with a control murine IgG2a Ab. rCD4 inhibited HIV replication by 90% if added to M/M within 3 days after viral challenge, while OKT4A lost its antiviral effect if added >24 hours after viral exposure. Conclusions. OKT4A and soluble CD4, which block CD4-gp120 binding, are highly effective inhibitors of infection of blood-derived M/M by HIV, providing evidence that CD4 is the principal if not sole receptor for HIV in M/M.

M.C.P.51

HELA CELLS STABLY EXPRESSING HIV ENV AND TAT AS TOOLS FOR STUDYING STRUCTURE, FUNCTION AND CANDIDATE INHIBITORS OF THESE KEY HIV GENE PRODUCTS.

Gama Sosa, M.; DeGasperi, R.; Fazely, F. and Ruprecht, Ruth M.
Dana-Farber Cancer Institute, Massachusetts General Hospital
and Harvard Medical School, Boston, Massachusetts, USA.

Objective. To stably express the env and tat gene products of HIV in HeLa cells, and to use such expressor cell lines to isolate these gene products for structure/function analysis. Methods. A DNA fragment containing the tat, rev and env genes from the HIV-1 infectious clone pHXBc2 was cloned into the retroviral shuttle vector pZIPneoAU3. The resulting plasmid penvAU3 was transfected into human cells, and transformants (HeLa env⁺tat⁺ clones) were selected in G-418 containing medium. Results. Stable expression of HIV env was demonstrated by immunoprecipitation with AIDS patient antisera which showed clear bands of molecular weights 160, 120 and 41 kD after lentil lectin chromatography. HIV env expression in these HeLa cell clones has been demonstrated for over 6 months. A functional assay for env based on syncytium formation was performed as follows: Hela env⁺tat⁺ cells were cocultivated with indicator HeLa T4⁺ containing the chloramphenicol acetyl transferase (CAT) gene under the transcriptional control of the HIV LTR (kindly provided by Drs. B. Felber and G. Pavlakis). Transactivation of the CAT gene was observed after cocultivation of indicator cells with HeLa env⁺tat⁺ but not with wild type HeLa cells. This transactivation was inhibited by OKT4A antibody. Likewise, inhibitors of glycoprotein processing such as castanospermine or its analogues inhibited CAT transactivation. Conclusions. The virus-free expression of the HIV tat and env will allow analysis of structure, function and inhibition of these gene products in a biohazard-free system.

M.C.P.53

USE OF AZT AS A CHEMOPREVENTIVE AGENT: EFFICACY AND TOXICITY IN MURINE RETROVIRUS INFECTIONS.

Bilello, John.*, MacAuley, C.*, Yetter, R.A.*, Shapiro, S.**, Frederickson, T.*, Bell, M.** and Eiseman, J.L.** VA Medical Center*, and University of Maryland**, Baltimore, MD. U.S.A.

Objective. To determine if AZT therapy can protect susceptible populations from retrovirus infection. Methods. AZT was administered to C57BL/6 or NFS/N mice prior to challenge with LP-BM5 or Cas-Br-M MuLV respectively. Results. 1) Treatment with AZT (1 mg/ml in drinking water, 4 weeks) protected newborn NFS/N mice from a single challenge with Cas-Br-M but was not able to prevent maternal-fetal transfer of LP-BM5 MuLV from infected C57BL/6 mothers. 2) AZT treatment of adult C57BL/6 mice suppressed LP-BM5 replication: upon removal of AZT, viral replication and disease was observed in a significant percentage of the treated mice. 3) Hematocrits fell dramatically in mice treated with high levels of AZT. 4) The hematopoietic toxicity was dose dependant, hyperplasia and elevations in spleen and bone marrow BFU-E were observed in mice treated by continuous infusion, indicating that AZT alters erythropoiesis in the absence of detectable anemia. Conclusion. The effectiveness of AZT as a chemopreventive agent depends upon the elimination of reservoirs of infection and the management of hematopoietic toxicity.

M.C.P.50

USE OF NUCLEIC ACID HYBRIDIZATION FOR HIV SUSCEPTIBILITY TESTING

*Cohen Stuart H, **Scholl DR, *Bolton V, **Loeffelholz M, *Jennings M, *Carlson JR
*University of California, Davis, Davis, California, USA and **Diagnostic Hybrids Inc, (DHI) Athens, OH, USA

Objective. Many antiviral compounds for Human Immunodeficiency Virus (HIV) infection are being studied using time consuming and tedious in vitro methods. We have developed and evaluated a new technological approach for antiviral susceptibility testing using a rapid and simple method for specimen processing known as "wicking". This technology has been adapted to successfully test the susceptibility of HIV to zidovudine (AZT). Methods. CEM cells (2×10^5) were infected with HIV (LAV-1) at approximately 850,000 reverse transcriptase units (RTU). After 1 hr adsorption the cells were washed x 3 and RPMI 1640 + 10% calf serum with AZT (5uM-0.01 uM) was added. Cells were incubated for 6 days, at which time the media was removed and cells were lysed with the RNA wicking agent (DHI). Hybridization of the wicks was carried out at 42°C for 2 hrs with an iodinated ss DNA probe containing 3.0 kb of the HIV clone pBENN#5. After a 1 hr wash at 50°C the wicks were counted in a gamma counter. Results. The Inhibitory Dose (ID50) for AZT by this method was ≤0.01 uM. This result was reproducible and paralleled RT assays and p24 Ag assays. Conclusion. We conclude that nucleic acid hybridization by wicking offers a method to study the effect of antiviral agents on the intracellular RNA of HIV. This technique should prove very useful for the rapid screening of antivirals and the study of resistance in clinical isolates.

M.C.P.52

RECOMBINANT GRANULOCYTE COLONY STIMULATING FACTOR (r-metHuG-CSF) AND RECOMBINANT ERYTHROPOIETIN (r-HuEPO) MAY ABROGATE THE NEUTROPENIA AND ANEMIA OF AIDS AND MAY ALLOW FOR RESUMPTION OF ZIDOVUDINE (AZT) IN PATIENTS WITH AIDS

Miles, Steven*; Mitsuyasu, R.*; Fink, N.*; McCarthy, S.*; Alton, K.; Souza, L.** and Glaspy, J.*.
*UCLA AIDS Center, Los Angeles, CA., USA and **Amgen, Inc. Thousand Oaks, CA., USA.

Objective. To see if combined r-metHuG-CSF/rHu-EPO therapy can correct neutropenia and anemia in patients with AIDS and allow for the resumption of full or higher doses of AZT. Methods. Phase I/II Open Label Trial of r-metHuG-CSF/r-HuEPO/AZT in patients with AIDS/severe ARC. Patients with absolute neutrophil counts (ANC)< 2500/mm³ and hemoglobin (Hb)< 11.5 gm/dl (off all marrow suppressive drugs including AZT > 3 weeks) were treated with r-metHuG-CSF one daily subQ dose until a ANC of >6000 was achieved and maintained for 2 weeks. r-HuEPO (TIW) was added and increased until an increment of 1.5 gm. of Hb. over baseline was observed. Patient groups were then given 1000 mg., 1500 mg. or 2000 mg. of AZT per day. Results. Eleven of 24 patients have been enrolled. Of these, eight have completed the r-metHuG-CSF alone phase with a mean increase of 20,449 ± 9130 neutrophils. Four have completed the combined r-metHuG-CSF/r-HuEPO phase with normalization of their hemoglobin values (13.9 ± 0.6) and have resumed full dose AZT (1000 mg/d). One patient died unexpectedly and another was withdrawn for noncompliance during this phase. Both r-metHuG-CSF and r-HuEPO have been well tolerated. Toxicities were mild transient bone pain responsive to tylenol (5 pts.), and hypokalemia and/or hypophosphatemia in pts. with poor nutritional status and chronic diarrhea. Analysis of limiting dilution plasma and lymphocyte cocultures for HIV and p24 antigen levels showed no significant alterations in viral expression prior to resuming AZT. Conclusions. Recombinant-metHuG-CSF and r-HuEPO may abrogate the neutropenia and anemia of AIDS, is well tolerated and may allow the resumption of full dose AZT in AIDS patients without altering HIV expression. This combined therapy maybe of benefit to AZT intolerant AIDS pts.

M.C.P.54

PHOSPHORYLATION OF 3'-AZIDO-2',3'-DIDEOXYURIDINE, 3'-AZIDO-3'-DEOXYTHYMIDINE, AND THYMIDINE IN UNINFECTED AND HIV-1 INFECTED CEM CELLS

Eriksson, B. F. H.[1]; Oswald, B. J.[1]; Sommadossi, J. -P.[2]; Chu, C. K.[3], Williams, G.[4], and Schinazi, R.F.[1]

Veterans Administration Medical Center and Emory University School of Medicine, Atlanta, Ga.[1], University of Alabama, Birmingham, Al.[2], University of Georgia, Athens, Ga.,[3] and Triton Biosciences Inc., Alameda, CA, USA.[4]

Objective. To compare the anabolic phosphorylation of 3'-azido-2',3'-dideoxyuridine (AzddU; CS-87), 3'-azido-3'-deoxythymidine (AZT), and thymidine (dThd) in cell culture. Methods. Uninfected and HIV-1 infected CEM cells were incubated with [³H]-labeled AzddU, AZT, or dThd. A 60% methanol extract was prepared and HPLC-analyzed using a Synchropak AX-100 column. Alkaline-soluble and stable preparations were also analyzed to determine the amount of drug incorporated into RNA and DNA. Results. A 3-hour pulse-labeling of uninfected CEM cells indicated that AZT may be more rapidly phosphorylated than AzddU. No such difference was seen at 24 hr incubation. Both AzddU and AZT accumulated high levels of monophosphates with AZT-MP levels being at least 2-5 times higher (8-20 pmoles/10^6 cells). AzddU consistently generated a 5-10 times lower level of triphosphates than did AZT, which may explain the observed differences in HIV-inhibitory effects in cell culture. Pulse-labeling with 1 µM of either drug, however, generated triphosphate levels well above the reported K_i-values for HIV-1 reverse transcriptase. For AzddU and AZT, over 99% of total radioactivity was found in the methanol-soluble extracts and about 0.1% in the alkaline-stable preparations. The corresponding distribution of dThd was 20% and 80%, respectively. HIV-1 infection increased the amount of total radioactivity found in both the alkaline-soluble and alkaline-stable preparations from about 0.1 % to about 1% for AzddU and AZT. Conclusion. Although AzddU and AZT produced similar phosphorylation patterns, significantly lower levels of mono- and triphosphates of AzddU were found which may explain its lower activity and toxicity *in vitro*.

M.C.P.55 EFFECT OF DEHYDROEPIANDROSTERONE (DHEA) IN LYMPHOCYTES AND MACROPHAGES INFECTED WITH HIV-1

Schinazi, R.F.[1]*, Eriksson B.F.H.[1], Arnold, B.[1], Lukas, P.[2], and McGrath, M.S.[2]

Veterans Administration Med. Ctr, and Emory University Sch. of Med., Atlanta, Ga., USA[1], and AIDS Activities Division, UCSF San Francisco General Hospital, San Francisco, CA, USA.[2]

Objective. Since the spectrum of activity of DHEA and structural analogues against human retroviruses has not been reported, several *in vitro* studies were performed to determine the degree of antiviral selectivity and mechanism of action of these drugs.
Methods. The inhibition of HIV-1 multiplication in the various cells was determined by reverse transcriptase assay of disrupted virions obtained from culture medium or by a p24 assay. The methodologies have been described in detail (see *Antimicrob. Agents Chemother.* 33:115, 1989; 32:1784, 1988; 30:491, 1986).
Results. The ability of DHEA and 3'-azido-3'-deoxythymidine (AZT) to inhibit the replication of HIV-1 was examined in human peripheral blood mononuclear cells (PBMC). Reverse transcriptase (RT) activity associated with virus and the amount of HIV-1 p24 antigens in the supernatant were used to assess the antiviral activity. Using the former assay, the median effective concentrations for DHEA and AZT were 17 μM and 0.0014 μM, respectively. Results obtained by an enzyme immunoassay were similar. DHEA-sulfate was markedly less active than DHEA. In contrast, 16α-bromoepiandrosterone was more potent and also more toxic than DHEA. The specific antiviral activity of DHEA was confirmed in CEM cells. Although this steroid was still effective when added up to 3 days after infection, late treatment was not as effective as early treatment. DHEA did not have a direct virucidal effect on infectious virus. In contrast to the 5'-triphosphate of AZT and other known antiretroviral agents, DHEA did not inhibit HIV-1 RT enzymatic activity when tested up to 100 μM. Acute infection of normal human macrophages was also inhibited by DHEA at 10-100 μM. Multiple-drug effect analyses were used to quantitatively determine the interaction of AZT and DHEA in human PBMC infected with HIV-1 at a ratio of 1:1,000 and 1:4,000. Analyses of the cell culture data indicated mostly an antagonistic interaction. At therapeutic levels, no apparent toxicity to uninfected cells was observed.
Conclusion. Our studies indicated that DHEA was a modest selective inhibitor of HIV-1 replication in human lymphocytes and macrophages. The mechanism(s) involved in the antiviral activity of DHEA and its sulfated form must be on sites other than the HIV-1 RT. *In vitro* results revealed that the combination of AZT and DHEA may decrease the efficacy of AZT or exacerbate virus replication.

M.C.P.56 IN VITRO ACTVIVATION OF PERIPHERAL MONONUCLEAR CELLS OF HIV-INFECTED PATIENTS BY ZINC

T HARRER+, B WOLF*, M MISSMAHL+, W SCHWARZ*, D BERGNER*, JR KALDEN*
+MEDIZINISCHE UNIVERSITAETSKLINIK III *ZENTRALLABOR UNIVERSITY OF ERLANGEN-NUERNBERG, 8520 ERLANGEN, FRG

OBJECTIVE: Study of the effect of zinc on the in vitro proliferation of mononuclear blood cell from HIV-infected patients and healthy controls.
METHODS: $ZnCl_2$- and mitogen-induced in vitro proliferation on peripheral mononuclear cells was determined by incorporation of radioactive thymidine, zinc serum levels by atomic absorption spectrometry. The frequence of zinc reactive cells was studied by limited dilution techniques.
RESULTS: The optimal mitogenic effect of zinc was observed with a concentration of 0.05 mmol/l (normal zinc serum level: 0.011-0.0176 mmol/l) and after a median incubation time of 6 days.
In comparison to standard mitogens the mean mitogenic activity of zinc in 21 healthy controls was 65 % of the activity of ConA, 43 % of PHA and 213 % of PWM.
The zinc induced in vitro proliferation was correlated to the Walter-Reed-Classification in 30 HIV-infected patients. A normal proliferation (more than 50 % of a normal control) showed 4/4 persons in WR1, 13/16 patients in WR2. In WR3-WR6 the proliferation in all 10 patients was diminished (< 50% of control).
Reduced serum levels of zinc were detected in 9/28 HIV-infected patients and in 1/16 controls.
The frequency of zinc reactive mononuclear cells in 5 healthy controls amounted to 1/4096 (1/2048-1/8192).
CONCLUSION: Zinc has a potent mitogenic activity on mononuclear cells which is decreasing with progressive immunodeficiency.
Further study about the mechanism of Zinc-induced activation of lymphocytes is necessary to define the value of a therapeutic zinc substitution.

M.C.P.57 OCULAR DIFFUSION OF DHPG AFTER SYSTEMIC ADMINISTRATION : ANIMAL STUDY AND APPLICATION TO A CLINICAL CASE

F.CHAST, F. FAUVELLE, S. CALLAERT, O. CARTON, M.SAUVAGEON-MARTRE.
Service de Pharmacie de l'Hôtel-Dieu - Paris, FRANCE.

Objective : DHPG (Ganciclovir, Cymevan®) has shown therapeutic effects in the treatment of cytomegalovirus retinopathy in AIDS patients. Pharmacokinetics and ocular diffusion of DHPG into anterior and posterior eye segments was determinated after IV infusion of DHPG in rabbits.

Method: 10 mg/kg bolus of DHPG was administered to 9 New-Zealand albino rabbits (2,5±0,1 kg) and blood was sampled at different time during 6 hours. Drug penetration into aqueous and vitreous humors was evaluated after sacrifice by sampling at the 6th hour. In a patient receiving DHPG 10 mg/kg/d (b.i.d.) for the treatment of a viral retinitis, and vitrectomized, blood and vitreous humor were sampled at the 5th hour after the last administration of DHPG (5 mg/kg).
Drug levels were determinated by reversed phase HPLC (C 18 - mobile phase = potassium dihydrogen phosphate 0,02 M, sodium heptan sulfonate 0,005 M / acetonitrile, 97,5 : 2,5, v/v, 1 ml/min) with a spectrophotometric detection at 265 nm.

Results :

	C max (mg/l)	T1/2 h	Clp ml/min	Vd l/kg	Biological fluids concentrations at the 6th hour (mg / l)		
					Plasma	Aqueous H.	Vitreous H.
Mean	9,02	1,50	49,9	1,64	0,21	1,51	0,99
S.E.M.	1,26	0,41	17,1	0,26	0,13	0,63	0,28

In the patient, plasmatic and vitreous DHPG levels were respectively of 6,5 mg/l and 0,3 mg/l.

Conclusion: The DHPG ocular pharmacokinetics seems to validate the treatment of CMV retinitis by systemic DHPG administration (DI_{50} of human CMV being 0,2-2,5 mg/l). In addition, intravenous administration would be much more convenient than intravitreous administration.

M.C.P.58 POTENTIAL OF AUTOCATALYTIC SELF-CLEAVING RNAs AS ANTI-HIV AGENTS

M. Sarver, J. McGowan and Margaret I. Johnston, Developmental Therapeutics Branch, AIDS Program, National Institute of Allergy and Infectious Diseases, Natl. Institutes of Health, Rockville, MD 20892, USA.

Certain naturally occurring plant viruses, linear satellite RNAs and newt satellite RNA (Epstein and Gall (1987), Cell 48: 535) (ribozymes) undergo self-catalyzed cleavage in the final step of a rolling circle RNA replication mechanism that generates unit-length (+)RNA or (-)RNA. A single ribozyme contains all the structural information necessary for self-cleavage. This property of self-cleavage is imparted by consensus sequences (GU(X)nCUGA(U/A)-GAG(X)nCGAAAC) derived from three distal regions of the molecule; a tertiary ("hammerhead") conformation is believed to bring these reactive groups into close proximity prior to autocatalytic cleavage. Other autocatalytic motifs distinct from the hammerhead have been described. Importantly, the consensus domains and secondary structure required for hammerhead cleavage can be achieved using separate target substrate and ribozyme antisense strands (Uhlenbeck (1987), Nature 328:596). Thus, an appropriately designed ribozyme antisense strand can combine with a specific target substrate containing a minimally conserved consensus target sequence and result in cleavage of the target strand. HIV-1 genomic RNA and mRNA's have been found to contain conserved sequences that are potential substrates for cleavage by appropriate ribozyme antisense sequences. Delivery of ribozyme antisense sequences to HIV-infected cells by viral vectors represents a novel potential anti-HIV strategy. This ribozyme strategy,which will be outlined, may have broad implications for the treatment of a variety of infections and other diseases in addition to AIDS and its sequela.

M.C.P.59 IMPACT ON AIDS CLINICAL TRIALS OF THE USE OF NON APPROVED THERAPIES

Bihari, Bernard*
*SUNY Health Science Center, Brooklyn, N.Y., U.S.

There is growing use by people with HIV related illness of non approved therapies. Some (such as aerosol pentamadine for PCP prophylaxis, disulfiram and naltrexone) are FDA approved for other uses and are available by prescription. Others (such as Dextran Sulfate, AL 721, DHEA) are obtained by patients through buyers clubs, with or without their physicians recommendations. There is growing evidence that many patients in clinical trials which preclude the concomitant use of these drugs are nonetheless taking them without so informing the investigators. This pattern has serious implications for validity of data obtained in such trials and therefore for FDA decisions. In addition, well controlled trials of these substances, some of which seem promising are becoming more difficult as patients are not willing to risk receiving a placebo of a drug which they can obtain elsewhere. Possible remedies for this problem are explored and discussed. They include: (1) Modification of trial design in some studies permitting the continuation of non approved drugs as long as they have been in continuous use for at least 3 months and are not discontinued during the trial. The use in such trials of larger sample sizes and multivariate analysis to factor out the effects of non approved drugs. (2) The use of placebo controls in trials of these available drugs only in asymptomatic seropositive patients, with the use of progression in biological markers rather than development of AIDS as criteria for efficacy. (3) The substitution of dosage comparisons for placebos in the study of these drugs (as in the current U.S. trials of aerosol pentamadine). (4)The study of large populations in community settings to evaluate possible effects of the "naturally" occurring patterns of non approved drug use. (5) Consideration by the FDA (or an FDA advisory panel) of modifications in standards of proof of efficacy for drugs that are already FDA approved for other purposes and for drugs with demonstrably low toxicity.

M.C.P.60 PRELIMINARY RESULTS FROM AN ON-GOING PROSPECTIVE EVALUATION OF FOSCARNET IN THE TREATMENT OF AIDS-ASSOCIATED CYTOMEGALOVIRUS RETINITIS

Ussery, Fred M., III*; Karol, C**; Conklin, R*; Gathe, J*; Stool, E*; Redding, K* *Foscarnet Research Project, Park Plaza Hospital, Houston, Texas, USA. **Astra Pharmaceutical Products, Inc., Westborough, Ma., USA.

Objective. To evaluate the efficacy, toxicity, and pharmacodynamics of a new agent for the treatment of CMV retinitis in AIDS, FOSCARNET.
Methods. Eight patients with previously-untreated AIDS-associated CMV retinitis and 12 patients with CMV retinitis previously treated with ganciclovir with either treatment failure or disqualifying drug toxicity were enrolled in a prospective clinical trial of foscarnet (Astra) using an intermittent, pump-controlled infusion technique at a 14-day induction dosage of 60 mg/kg every 8 hours, adjusted for creatinine clearance. These 20 patients were stratified into two protocols, (01) for previously-untreated patients, and (02) for patients having had prior ganciclovir therapy. Protocol (01) included both induction and maintenance phases, while the (02) protocol consisted of only an induction phase so that time to recurrence could be measured. Sequential indirect ophthalmoscopy with fundus mapping and wide-angle standardized fundus photography were utilized to assess clinical response.
Results. One of 14 eyes (7%) in (01) demonstrated total cessation of viral activity clinically at the end of induction; 12 eyes (87%) stabilized, and 1 eye (7%) progressed by ophthalmoscopic criteria. One of 21 eyes (5%) in (02) deactivated, 16 eyes (76%) stabilized, and 4 eyes (19%) progressed. Visual acuity remained within 2 Snellen lines of the pre-treatment level in 93% of the (01) patients and in 100% of the (02) patients. CMV cultures of buffy coat reverted from positive to negative in 83% of initially-positive patients at the end of induction, while HIV p24 reverted from positive to negative in 67% of the 9 patients initially having detectable p24. Mean time to recurrence in (02) was 13 days. Elevation of serum creatinine above 2.8 occurred in 4 of the 20 patients. Six patients experienced significant nausea, and various transient neurological disturbances occurred in 10 of the 20 patients. AZT therapy was continued during foscarnet induction in 5 patients; only 1 demonstrated significant depression in hematological parameters, however AZT could be continued even in this patient.
Conclusion. Our continuing experience with foscarnet in this projected 120-patient clinical trial indicates considerable efficacy in treating CMV retinitis. We are developing various means of minimizing side-effects of this promising antiviral agent. Concurrent anti-HIV activity of foscarnet in CMV retinitis patients adds significant interest to the project.

M.C.P.61

SHORTENING THE RESEARCH AND DEVELOPMENT TIME FOR NEW AIDS DRUGS: THE PRE-IND PROGRAM AND PROACTIVE CLINICAL GUIDANCE AT FDA'S DIVISION OF ANTIVIRAL DRUGS.

Peter C. Hoyle, Ph.D. and Ellen C. Cooper, M.D., Division of Antiviral Drug Products, U.S. Food and Drug Administration, Rockville, MD. USA

The U.S. Food and Drug Administration (FDA) Division of Antiviral Drug Products (DAVDP) is responsible for the regulation of pharmaceuticals indicated for the treatment of AIDS and AIDS-related disorders in the U.S. The primary role of DAVDP scientists and physicians is to expeditiously review the nonclinical and clinical efficacy and toxicity data in Investigational New Drug Applications (INDs) and New Drug Applications (NDAs). However, to facilitate the rapid preclinical and clinical research and development of new AIDS drugs so that promising new therapies will be available without delay, DAVDP has created two programs for providing detailed guidance to drug developers during all phases of drug development, from the earliest preclinical studies, throughout clinical trials, to market approval. These programs focus on making the DAVDP reviewer's expertise in drug development available to pharmaceutical firms and individual investigators worldwide. The goal of the Pre-IND Program is to focus the drug developer's preclinical development program on those specific studies necessary to rapidly complete the preclinical work-up of promising new AIDS drugs, and move the drugs into well-designed clinical studies as quickly as possible. The purpose of the Proactive Clinical Guidance is to help the sponsor optimize the design of clinical trials to produce the most useful data possible upon which marketing approval can be based. The AIDS drug-review process in DAVDP will be described, and contact points for the Programs will be provided. Major problems seen in the development of AIDS drugs and viable solutions to facilitate drug development will be discussed.

M.C.P.62

Low Dose Naltrexone in the Treatment of AIDS: Long Term Follow-up Results

Bihari, Bernard*; Drury, F*; Ragone, V*; Ottomanelli, G*; Cannon, G**; Klein, E***
*SUNY/Health Science Center at Brooklyn, **ImmuQuest Laboratories, Rockville, Maryland, ***St. Luke's-Roosevelt Hospital, New York

Objective. To evaluate the long term results of the treatment of AIDS with low doses (1.75 mg qhs) of naltrexone, an opiate antagonist.
Method. Thirty-eight patients with AIDS were treated in a 3 month placebo controlled trial of naltrexone, after which the placebo patients were switched to naltrexone and both groups followed on naltrexone since.
Results. During the placebo controlled period the treatment group showed significantly fewer O.I.s and a significant drop in their markedly elevated levels of αIFN. Twenty-five of the 38 patients while on naltrexone eventually showed a drop in αIFN levels from means of 160 i.u. to 11.75 i.u., over a 4 to 12 month period (called "responders"). The 13 patients whose interferon did not drop ("non-responders") all died within 9 months. Of the responder group 21/25 had survived at 12 months and 19/25 at 18 months. At 39 months 10 of the 25 responders are still alive, 4 years after AIDS diagnosis. Only one of these 10 has suffered an O.I. in the course of the trial. The other 9 are all working full-time and are essentially symptom free 4 years after AIDS diagnosis and 39 months after starting naltrexone. The mean T4 level in this group has not dropped during the trial. The responders also showed an increase in lymphocyte proliferative responses to PHA and have shown no decline in responses to CMV antigen. p24 antigen levels and anti p24 antibodies will be presented as well.
Conclusion. Low dose naltrexone may be a useful immunomodulating agent in AIDS related illness with 40% of responding patients with AIDS showing long term survival.

M.C.P.63

ANTI-HIV-1 ACTIVITY, TOXICITY AND PHARMACOKINETICS OF TOTALLY NOVEL NUCLEOSIDE ANALOGS

Wainberg, Mark A.***; Stern, M.*; Martel, R.*; Belleau, B.** and Soudeyns, H.***.
*IAF BioChem International Inc., Laval, Quebec, Can.; **Institut Armand-Frappier, Laval, Quebec, Can.; ***Jewish Gen. Hospital, Montreal, Quebec, Can.

Objective: To test a number of nucleoside analogs in which the 3'-carbon of the pentose is replaced by an S or O atom.
Methods: Cpds. were assayed for anti-HIV-1 activity (RT, p24 Ag, cell viability) in T-cell lines (H-9, MT-4) and a monocyte/macrophage cell line (U-937).
Results: The lead cpd. NGPB-21 (base = cyt, 3' = S) had a therapeutic index ≅ 1000 (sim. to AZT) and, unlike AZT, had no cell toxicity at therapeutic concs. Also, NGPB-21 was very active in the HIV-1 infected U-937 cell line. Rats given NGPB-21 at 100 mg/kg p.o. daily for 14 days showed no inhibition of body growth, and had normal organ wts. (liver, spleen, testis, kidney) and hematologic profile. Rats given NGPB-21 at 200 mg/kg p.o. readily absorbed the drug and had peak blood levels at 1.5 hr. and $t_{1/2} \cong 1.0$hr. Another cyt analog (DDIII30A) in which 3' = O and the sugar-base linkage is in the unnatural α-configuration showed a favorable therapeutic index in vitro.
Conclusion: NGPB-21 and DDIII30A are novel nucleosides showing high potential as anti-AIDS drugs.

M.C.P.64

ISOLEUCINE ESTER OF ZIDOVUDINE (IAZT) AS A PRO-DRUG WITH ENHANCED EFFICACY AGAINST HIV-1.

Agrawal, Krishna C., Aggarwal, S.K., Gogu, S.R., Lupia, R.H., Lertora, J.J.L., and Rangan, S.R.S.*
Department of Pharmacology and *Delta Primate Center, Tulane University School of Medicine, New Orleans, LA 70112, U.S.A.

Objective. To develop a pro-drug of zidovudine (AZT) with increased therapeutic index in an attempt to overcome the dose-related toxicity (anemia and neutropenia).
Methods. Among various approaches of developing pro-drugs, we have successfully inserted an amino acid, isoleucine, at the 5'-OH function of AZT by esterification. Peripheral blood lymphocytes (PBL) from seronegative donors were employed to determine cellular drug uptake, cytotoxicity and anti-HIV-1 activity. Murine bone marrow cells were used to determine toxicity by ^{3}H-thymidine incorporation. Preliminary pharmacokinetic studies were conducted in rabbits.
Results. Cellular uptake studies in PBL demonstrated that ^{3}H-IAZT achieved approximately 60% greater intracellular concentration than ^{3}H-AZT within 2 hr. IAZT was significantly less toxic than AZT at various concentrations to murine bone marrow cells as measured by uptake of ^{3}H-thymidine. The ED$_{50}$ concentration to inhibit the production of HIV-specific p24 antigen was 0.035 μM for IAZT whereas AZT required twice the amount of 0.07 μM level. Preliminary pharmacokinetic experiments in rabbits demonstrated a 2-compartment model in plasma with a β-elimination $T_{1/2}$ of 105 min for AZT and 187 min for IAZT.
Conclusion. These results demonstrated that IAZT has a higher therapeutic index than AZT as an anti-HIV-1 agent.
(Supported by NIAID grant No. AI-25909)

M.C.P.65

THE CARBOCYCLIC ANALOGUE OF OXETANOCIN G INHIBITS THE REPLICATION OF CYTOMEGALOVIRUS AND HERPES SIMPLEX VIRUSES IN VITRO.

Norbeck, Daniel*, Rosenbrook, W.*; Plattner, J.*; Erickson, J.*; Arnett, G.** and Shannon, W.** *Abbott Labs, Abbott Park, Ill, USA, **Southern Research Inst. Birmingham, Ala, USA

Objective. To evaluate the in vitro antiviral activity of the newly synthesized (±)-9-[2',3'-bis(hydroxymethyl)-1'-cyclobutyl]guanine (A-69992) against human cytomegalovirus (HCMV) and herpes simplex viruses type 1 and type 2 (HSV-1 and HSV-2).
Methods. The antiviral activity of A-69992 against HSV-1 and 2 was determined in Vero cells using a virus induced cytopathogenic effects (CPE)-inhibition assay. The minimum drug concentration which reduced the microscopically observed CPE by 50% (ID$_{50}$) was calculated by regression analysis, and drug toxicity was determined in uninfected control cells. Ara-A and acyclovir were tested concomitantly. Activity against HCMV was determined in a virus yield reduction assay in human diploid embryonic lung (MRC5) cells. After 6 days, drug cytotoxicity was quantitated by the ability of viable host cells to reduce the tetrazolium salt (MTT), and the relative yield of infectious virus from the drug treated and untreated cultures was determined by plaque assay in MRC5 cells. Ganciclovir was tested concomitantly.
Results. The following ID$_{50}$'s were determined for A-69992 and acyclovir (virus, ID$_{50}$ (ug/mL) for A-69992, ID$_{50}$ for acyclovir): HSV-1(E-377), 0.57,0.43; HSV-2(MS), 1.00, 1.80; HSV-1(BW 10168 TK deficient), 4.06, 13.03; HSV-2(BW9787 TK deficient), 0.79, 12.65. A-69992 was partially cytotoxic to Vero cells at 100 ug/mL, while acyclovir showed no cytotoxicity at 225 ug/mL. At a nontoxic concentration of 32 ug/mL, A-69992 reduced the yield of infectious HCMV in MRC5 cells from $10^{4.27}$ PFU to below the detection limit ($<10^{0.5}$ PFU). At the lowest concentration tested, 1.0 ug/mL, the yield of infectious virus was reduced 14 fold. At the highest concentration tested, 320 ug/mL, the drug cytotoxicity was 24%. By comparison, ganciclovir appears to be about 10 times as potent as A-69992 in this system.
Conclusion. A-69992 exhibits selective in vitro antiviral activity against HSV-1, HSV-2, and HCMV at concentrations as low as 1 ug/mL, and it is more potent than acyclovir against TK deficient strains of HSV. These observations, and those of Hayashi et al ("Carbocyclic Oxetanocin Analogues that Inhibit Replication of Human Immunodeficiency Virus in T-Cells and Monocytes/Macrophages In Vitro"), may be of value in developing a new drug therapy for AIDS.

M.C.P.66

INHIBITION OF HUMAN IMMUNODEFICIENCY VIRUS INFECTIVITY BY CHLOROQUINE.

Tsai, W.-P.*, Nara, P.L.**, Kung, H.-F.*, and Oroszlan, Stephen***.
*Laboratory of Biochemical Physiology, and ** Laboratory of Tumor Cell Biology, National Cancer Institute, Frederick, MD, ***BRI-BRP, NCI-Frederick Cancer Research Facility, Frederick, MD, U.S.A.

The effect of chloroquine, an anti-malarial drug known to affect cellular exocytic pathways, was studied in two retroviral systems: Human Immunodeficiency Virus (HIV-1) and avian reticuloendotheliosis virus (REV-A). With chloroquine treatment of virus infected cells (HIV-1/H9 and REV/cEMC), significant size reduction of the cell and virus associated surface glycoproteins, gp90 of REV-A and gp120 of HIV-1, was observed. In the case of HIV-1, extracellular virions derived from treated cells contained very little gp120. Infectivity and reverse transcriptase assays carried out with HIV-1 demonstrated that by chloroquine treatment virus yield was reduced and noninfectious virions were released. The data suggests that inhibition by chloroquine is most likely due to interference with terminal glycosylation in the trans-Golgi network. Studies are in progress to determine the effect of chloroquine on HIV-1 and its relatives produced by other cell types e.g. monocytes/macrophages and to evaluate whether chloroquine and its existing analogs or newly synthesized related weak bases could be useful either alone or in combination with other drugs to attack various stages of the virus life cycle.
(Research supported in part by the National Cancer Institute, DHHS, under contract NO. NO1-CO-74101 with Bionetics Research, Inc.)

M.C.P.67 NEUTRALIZATION OF HIV-1 BY ANTI-IDIOTYPIC ANTIBODIES

Leturcq, Didier*; Winslow, B.*; Johnson, P.* *; and Thornton, G.*.
*R.W. Johnson Pharmaceutical Research Institute,La Jolla,CA,USA,
** Georgetown University, Rockville,MD,USA.

Objective. To evaluate the ability of anti-CD4 monoclonal antibodies to elicit anti-idiotypic antibodies that are capable of binding to and neutralizing HIV.
Methods. Macaque monkeys were immunized (IV) with purified 0KT4A Mab and 6 months later with OKT4F (10 day injection protocols). The anti-CD4 antisera were assayed for anti-idiotypic antibody by competition ELISAs and for internal image (CD4-like reactivity, i.e. binding to HIV) using a commercial HIV antibody detection kit. To determine HIV neutralizing titers *in vitro*, MT-4 cells, preincubated with serially diluted antisera in 96-well microtiter plates, were exposed to H9/HIV clarified supernatant for 2 hrs at 4°C. Cultures were incubated for 7 days and developed colorimetrically with MTT.
Results. At the end of the OKT4A immunization protocol, anti-idiotype and anti-HIV titers appeared immediately. Neutralizing antibody titers were detected 5-14 days *post* immunization. Following OKT4F, anti-HIV and neutralizing titers were found to be slightly higher.

SERA	ANTI-OKT4A TITER	ANTI-OKT4F TITER	ANTI-HIV TITER	NEUTRALIZING TITER
Prebleed	<1:100	<1:100	<1:100	<1:10
2wk *post* OKT4A	1:1200	ND	1:400	1:40
6mo *post* OKT4A	1:3200	ND	1:100	1:20
2wk *post* OKT4F	1:3200	1:12800	1:1600	1:80

Conclusion. Anti-idiotype antibodies were raised in response to anti-CD4 monoclonal antibodies which were able to bind and neutralize HIV, *in vitro*.

M.C.P.68 PHOSPHONOFORMATE INHIBITS FELINE RETROVIRUS INFECTION IN CATS

Swenson, Cheryl L.; Weisbrode,S.E.; Sams,R.; Nagode,L.; Hayes,K.; Mathes,L.E.; et al.
The Ohio State University, Columbus, Ohio, USA.

Objective. To determine in vitro and in vivo efficacy and toxicity of phosphonoformate (PFA) against feline leukemia virus (FeLV).
Methods. PFA-induced inhibition of FeLV infection feline lymphoid cells (3201) was determined by reverse transcriptase (RT) assay. Pharmacokinetics studies were performed in young and adult cats. For prophylactic studies, six cats received 1000 mg/kg/day PFA as a continuous IV infusion for 1 day prior to and 4 weeks post-FeLV challenge. Six control cats received 120 U/kg/day heparin in saline. Six cats served as challenge controls. Histomorphometric determinations were performed on the distal radius of young and adult cats given 1000 mg/kg/day PFA and on age-matched control cats.
Results. FeLV infection of 3201 cells was inhibited by >90% at 64 uM PFA as measured by RT activity. Young cats exhibited a higher (2X) plasma clearance of PFA than adult cats, which was attributed to enhanced bone accumulation. Mean oral bioavailability was 35%. Continuous IV infusion of PFA (1000 mg/kg/day) prevented FeLV viremia in 4 of 6 cats. Six of 6 untreated challenge controls became viremic by 3 weeks post-inoculation. Plasma biochemical changes demonstrated in PFA treated cats compared with sham-operated controls included: increases in calcium and decreases in phosphorus, alkaline phosphatase and calcitriol. Bone histomorphometry revealed rickets-like lesions in young cats and osteomalacia in adult cats given 1000 mg/kg/day of PFA for 14 days.
Conclusion. PFA prevents FeLV infection in vitro and in vivo. High doses of PFA induce rickets in young cats and osteomalacia in adult cats.

M.C.P.69 PHARMACOKINETICS, TOXICITY AND PROPHYLACTIC ANTIVIRAL ACTIVITY OF PMEA IN FELINE RETROVIRUS INFECTED CATS

Mathes, Lawrence E.; Swenson,C.L.; Polas,P.A.; Sams,R.; Hayes,K. and Kociba, G.
The Ohio State University, Columbus, Ohio, USA.

Objective. To determine the pharmacokinetics, toxicity and prophylactic antiviral activity of 9-((2-phosphonylmethoxy)ethyl)-adenine (PMEA) in feline leukemia virus infected cats.
Methods. Pharmacokinetics and bioavailability of PMEA was determined in 6 cats at three doses. In prophylactic studies, 3 different dosage regimens of PMEA (100, 25 or 12.5 mg/kg/day) were evaluated for toxicity and antiviral activity in vivo. In all prophylactic studies PMEA was administered by continuous IV infusion beginning one day prior to FeLV challenge. Toxicity was evaluated as part of the prophylactic testing.
Results. PMEA administered at doses greater than 12.5 mg/kg/day continuous IV infusion, were toxic to severely toxic, causing death in 3 of 7 animals treated. The most prominent clinical feature in these animals was hemolytic anemia. A dosage of 12.5 mg/kg/day PMEA administered by continuous IV infusion for 3 wks prevented or delayed the onset of infection in 6 of 6 challenged animals. Moderate anemia was evident in these animals at the end of 3 wks of treatment. By comparison 7 of 7 control cats developed chronic viremia by 3 wks post challenge. All PMEA treated cats remain FeLV negative after 5 wks post challenge.
Conclusion. Though moderately toxic in cats at a dose of 12.5 mg/kg/day continuous IV infusion for 3 wks, PMEA was highly effective as a prophylactic treatment for preventing FeLV infection of cats for the period so far observed. Lower dosage regimens are currently being evaluated.

M.C.P.70 PHOSPHATE TRIESTER DERIVATIVES OF AZT AS INHIBITORS OF HIV

McGuigan, Chris*; Devine, K.*; O'Connor, T.**; Galpin, S.**; Williamson, J.D.**; Kinchington, D.**.
*University College, London, UK, **St Mary's Hospital Medical School, London, UK.

Introduction. A series of 20 phosphate triester derivatives of AZT have been tested against HIV-1 (HTLV III, RF strain) in the C8166 CD4+ T-cell line. These pro-drugs have been designed as membrane soluble compounds in order to overcome some of the limitations shown by AZT and other nucleoside analogues; such as kinase dependance, metabolic instability and poor membrane penetration. It has been found that asymmetrically substituted phosphates of AZT are active antiviral agents especially when one phosphate moiety is an amino-linked amino-acid, and the other is an alkyloxy chain.
Results. Depending upon the nature of the substituents large differences in the antiviral effect are observed. In the compounds below changes in the alkyloxy chain (X) and the amino acid (Y) gives a range of activities (IC_{50}) from 3 - 100 uM. Studies to investigate the nature of the block in HIV replication are in progress.

M.C.P.71 FLUCONAZOLE TREATMENT OF ESOPHAGEAL CANDIDIASIS IN AIDS PATIENTS.

A GIL, P LAVILLA, A GONZALEZ, ME VALENCIA, JML DUPLA, JJ VAZQUEZ.
Hospital La Paz, Madrid, Spain.

Aims of the study: To assess the efficacy and safety of Fluconazole in the treatment of esophageal candidiasis in AIDS patients.
Results: 36 patients (25 male and 11 female) were included. Mean age was 28 years (range: 19-55). There were 30 IV drug abusers, 5 homosexuals and 1 heterosexual contact. In all cases, esophageal candidiasis was confirmed by endoscopy, biopsy and/or culture. Therapeutic regime: 200 mg (1st day) followed by 100 mg daily p.o. for 4 weeks. Endoscopy control was carried out at the end of the treatment. A follow up visit 1 month after treatment was scheduled. Careful drug surveillance was performed in all patients. Therapeutic evaluation was performed in 33 patients, although only 31 completed treatment. The study was carried out over a ten month period (February-December 1988). During this time 8 patients died; 4 in the protocol stage and a further 4 after completing treatment, all of these due to other opportunistic infections.
Clinical and mycological cure was achieved in all patients; in most, clinical picture resolved within a week. In 2 patients an esophageal relapse ocurred 1 month after treatment. Re-treatment with Fluconazole achieved cure again. In a further 9 patients asymptomatic oropharingeal fungal colonization was observed. No gastrointestinal, hematological, renal or cutaneous toxicity was observed. Elevations of liver enzymes: discrete (15 patients), moderate (1 patient) and severe (1 patient), the latter leading to drug discontinuation, were recorded. Increases of alkaline phosphatase without hyperbilirubinemia (29%) was the most commonly observed adverse effect; however, it has to be taken into account that most patients had coexisting opportunistic infections and/or received potentially hepatotoxic concomitant therapy.
Conclusions: 1) Fluconazole has shown to be an effective and safe treatment of esophageal candidiasis in AIDS patients. 2) A shorter treatment may be efficacious in this condition. 3) An effective prophylactic regime with Fluconazole in these patients would be most desirable.

M.C.P.72 RECOMBINANT SOLUBLE CD4 AS A VEHICLE TO DELIVER RICIN TO HIV-ENVELOPE EXPRESSING CELLS

Cochran, Nancy A.*; Collinson, A.R.*; Liu, T.**; Meier, V.**; Rosa, M.D.**; Goldmacher, V.S.*. *ImmunoGen, Inc., Cambridge, MA, USA, **Biogen, Inc., Cambridge, MA. USA.

Objective: To assess the effectiveness of recombinant soluble CD4-blocked ricin conjugate (rsT4-bR) as a potential drug for the elimination of HIV-envelope expressing cells, in vitro.
Method: Intact ricin was covalently modified such that it retains ricin's ability to efficiently penetrate intracellular and plasma membranes but can no longer bind to cells through its natural binding sites. Blocked ricin (bR) was then covalently linked to rsT4 and the conjugate was tested in a number of in vitro assays. Cytotoxicity and specificity of killing were tested on gp160 expressing CHO cells and HIV-infected human T cells. Binding efficiency of rsT4-bR to gp120 was assessed in an EIA using recombinant gp120 (rgp120).
Results: rsT4-bR conjugate retained the capacity to bind to gp120 in an EIA. The cytotoxicity of the rsT4-bR conjugate was specific to HIV-envelope expressing cells; gp120 expressing CHO cells were effectively killed between 10^{-9} and 10^{-11}M rsT4-bR. Unmodified rsT4 completely blocked the rsT4-bR mediated killing. Untransfected CHO cells and CHO cells expressing a non-related recombinant protein were not affected at these concentrations. Experiments with HIV-infected human T cells confirmed these observations.
Conclusion: We demonstrated that blocked ricin conjugated to recombinant soluble CD4 selectively kills HIV-envelope expressing cells, in vitro, at concentrations that are achievable in vivo.

M.C.P.73 EFFECTS OF DIDEOXYNUCLEOSIDES ON THE CELL CYCLE

Smith, Camilla M. and Henderson, J.F. Cancer Research Group, University of Alberta, Edmonton, Alberta, T6G 2H7, Canada.

Objective. Antiviral dideoxynucleosides (ddN) are toxic to normal animal cells, though this varies with cell type and drug used. Mechanisms of cellular toxicity are not known. Here we report studies of the effects of dideoxynucleosides on the progression of cultured lymphoid cells through the cell cycle.
Methods. Cell cycle parameters were measured by cytofluorography using human B-lymphoblast 6410, human T-lymphoblast MOLT-4, human promyelocytic leukemia HL-60, and mouse leukemia L1210 cells. ddN concentrations were 1 mM. ddN were growth inhibitory in all but one case; dideoxythymidine (ddT) was not toxic to MOLT-4 cells. Thymidine (TdR) and methotrexate (MTX) were used as controls.
Results. Treatment of 6410 cells resulted in the following changes: Azidothymidine (AZT), TdR and dideoxyguanosine (ddG) increased the proportion of S-phase cells, MTX increased G1 cells, while dideoxycytidine (ddC) and ddT had minor effects. In MOLT-4 cells, AZT increased S-phase cells, MTX increased G1 cells, while TdR, ddC, ddT and ddG had minor effects. In HL-60 cells, AZT, ddT and ddG increased S-phase cells, TdR and MTX decreased S-phase cells, while ddC had little effect. In L1210 cells, ddC, ddT, ddG and AZT increased S-phase cells while MTX and TdR increased G1 cells.
Conclusions. Individual ddN have different effects on the cells cycle. The effects of individual ddN vary with the cell type. The effects of ddN on the cell cycle differ from those of TdR and MTX.

M.C.P.74 IN VIVO ANTI-RETROVIRUS AND ANTI-CYTOMEGALOVIRUS ACTIVITY OF 9-((2-PHOSPHONYLMETHOXY)ETHYL)ADENINE (PMEA).

Bronson, Joanne J.; Ghazzouli, Ismail; Hitchcock, Michael J. M.; Kern, Earl R.*; Martin, John C.
Bristol-Myers, Wallingford, CT, US *University of Alabama, Birmingham, AL, US

Objective. In vivo evaluation of the acyclic nucleotide analogue PMEA for the treatment of retrovirus and cytomegalovirus infections.
Methods. PMEA was prepared on a multigram scale in 35% overall yield via a six-step synthetic sequence. Rauscher murine leukemia virus was used to study the antiviral activity of PMEA compared with AZT against retrovirus infection in vivo. The antiviral effect of each compound was shown by inhibition of splenomegaly caused by viral infection. PMEA was also evaluated in vivo in a murine CMV infection model. Mice were treated i.p. with PMEA or ganciclovir (DHPG) at 6, 24, or 48 hours post-infection for five days. Antiviral efficacy was demonstrated by an increase in the survival time of treated animals compared with untreated and placebo-treated controls.
Results. Although PMEA was slightly less potent than AZT in vitro against HIV and murine retroviruses, PMEA was more effective than AZT in vivo in the treatment of R-MuLV infection in mice: at a dose of 40 mg/kg/day for 30 days, PMEA gave 85% inhibition of splenomegaly vs. 67% for AZT. PMEA also provided significant protection against murine CMV, giving 93% survival (vs. 33% for untreated animals) when administered 6 h post-infection at a dose of 100 mg/kg/day. Even when this treatment was delayed for 48 h, 67% of treated animals survived. DHPG provided a similar effect at 33 mg/kg/day.
Conclusions. The broad-spectrum in vivo antiviral activity of PMEA warrants the further investigation of its potential in the chemotherapy of retrovirus and cytomegalovirus infections.

M.C.P.75 COMPARATIVE INHIBITORY EFFECTS OF SULFATED POLYSACCHARIDES ON GIANT CELL FORMATION INDUCED BY CO-CULTIVATION OF CD4-POSITIVE CELLS WITH PERSISTENTLY HIV-1-INFECTED CELLS

Masanori Baba, D. Schols, R. Pauwels, H. Nakashima, J. Balzarini and E. De Clercq.
Rega Institute for Medical Research, K.U.Leuven, B-3000 Leuven, Belgium

Objective. In the scope of our attempts to develop an effective chemotherapy for AIDS, various compounds were examined for their inhibitory effects on HIV-1-induced giant cell (syncytium) formation, which may be an important mechanism of the depletion of CD4-positive cells in AIDS patients.
Methods. MOLT-4 cells were cultured with an equal number of chronically HIV-1-infected HUT-78 cells (HUT-78/HTLV-III_B) for 24 h in the presence of various concentrations of the test compounds, and the number of giant cells was counted.
Results. Sulfated polysaccharides such as dextran sulfates (MW > 5000), pentosan polysulfate, fucoidan, mannan sulfate and λ-carrageenan were potent inhibitors of giant cell formation (ID_{50}: 2-20 μg/ml). However, low-molecular-weight dextran sulfates (MW < 3000), dermatan sulfate and heparin showed little or no inhibition. Carboxylate polymers, such as polyacrylic acid and chlorite-oxidised oxyamylose (COAM) also failed to inhibit giant cell formation. Whereas azidothymidine was not inhibitory, suramin inhibited giant cell formation.
Conclusion. Several sulfated polysaccharides were found to be potent inhibitors of HIV-1-induced giant cell formation *in vitro* and should be further pursued as candidate anti-AIDS drugs.

M.C.P.76 NEUTRALIZATION OF HIV-1 BY ANTI-IDIOTYPIC ANTIBODIES

Leturcq, Didier*; Winslow, B.*; Johnson, P.* *; and Thornton, G.*.
*R.W. Johnson Pharmaceutical Research Institute,La Jolla,CA,USA,

2wk *post* OKT4F	1:3200	1:12800	1:1600	1:80

Conclusion. Anti-idiotype antibodies were raised in response to anti-CD4 monoclonal antibodies which were able to bind and neutralize HIV, *in vitro*.

M.C.P.77 INHIBITION OF HIV REPLICATION IN CELL CULTURE BY ANTI-SENSE RNA EXPRESSED FROM RECOMBINANT MURINE RETROVIRUSES

Rhodes, Andrew and James, William, Sir William Dunn School of Pathology, University of Oxford, U.K.

In principle, antisense nucleic acids offer an appealing approach to the rational design of anti-viral therapies of high selective toxicity. Antisense genes delivered by retroviral vectors offer some theoretical advantages over the use of synthetic oligonucleotides although it will be many years before they will be therapeutically useful. In addition, such recombinant vectors can be used to analyse the mechanism of antisense action and to analyse fundamental areas of HIV biology. Accordingly, we have inserted fragments derived from the region around the first coding exon of *tat/rev* of the HIV provirus in the antisense orientation into murine retrovirus vectors and have investigated the effect of the transduced antisense genes upon the replication of HIV in susceptible cell lines.

In order to analyse defined sub-fragments of this region, we have inserted additional Sat1 sites at position 5436 in one case and 5582 in another. The antisense genes thus far analysed are as follows: AR2, 602bp spanning the *tat* and *env* splice acceptor sites and the initiation of translation of *tat*, *rev* and *env*; AR5, 114bp, splice acceptor and *tat* initiation; AR6, 70bp, *tat* initiation.

The HIV-susceptible cell lines tested so far are the myelomonocyte-like U937 and the T4-derived Jurkat. We have challenged the transduced cell lines together with their "wild-type" counterparts to CEM cell-derived HTLVIIIB at approximate multiplicities of infection (m.o.i) of 5:1 and 1:100 and monitored the production of HIV using the Dupont p24 antigen assay kit. The results show that anti-sense genes can reduce levels of HIV replication substantially in the short term. For example, in the Jurkat cell line, AR2, AR5 and AR6 reduce viral replication by 67%, 61.4% and 83.3%, respectively, at 7 days post-infection. However, virus eventually escapes from antisense inhibition of replication, with levels of inhibition declining to 48%, 28.5% and 64.6% in the second week post-infection.

We believe that the antisense RNA, expressed from an SV40 promoter, is present in sufficient quantity to inhibit the expression of viral transcripts to a substantial extent in the absence of Tat and Rev. However, when these regulatory gene products accumulate as a result of the low level of residual virus gene expression, the strength of the HIV promoter in the LTR increases and sense transcripts appear in quantities that are too great for inhibition by the fixed quantity of antisense RNA. Curiously, antisense genes that include the AR6 region, such as AR2 and AR5, are less efficient inhibitors of replication. Possibly, secondary structures incompatible with hybridization are adopted by longer RNAs.

M.C.P.78 MEGAKARYOCYTES OF HIV-SEROPOSITIVE INDIVIDUALS EXPRESS VIRAL RNA

Zucker-Franklin, Dorothea, Cao, Y.Z., and Kouri, Y.H.
New York University, New York, New York, U.S.A.

Objective: To elucidate the pathogenesis of thrombocytopenia associated with HIV-1 infection. Although immune mechanisms are usually held responsible for low platelet counts this does not provide a complete explanation. Inconsistencies include: 1) lack of compensatory megakaryocytosis, 2) some benefit from platelet transfusions, 3) a rise in platelet count shortly following treatment with AZT when the level of circulating antibodies or immune complexes are unlikely to have changed. Therefore, a direct effect of HIV on megakaryocytes (MK) was investigated. Methods: Megakaryocytes of 60 HIV-seropositive individuals were studied ultrastructurally and MK of 10 patients were subjected to in situ hybridization using a S-labelled HIV RNA probe. Results: While no intact virus particles were seen, the structural alterations in HIV-MK were distinctive from those in HIV-negative ITP or any myelodysplastic syndromes. There was marked blebbing of the peripheral zone and cytoplasmic vacuoles containing membrane processes. Numerous denuded MK nuclei were also found in marrows of patients with normal platelet counts. The megakaryocytes of 10/10 paptients examined by in situ hybridization unambiguously expressed viral RNA. Conclusion: Although immune mechanisms play a role in HIV-related thrombocytopenia, direct infection of megakaryocytes with the virus appears to be responsible for low platelet production.

M.C.P.79 INHIBITORY EFFECT OF SULFATED AMPHOTERICIN B ON THE PROLIFERATION OF HIV IN VITRO

Toru Otake, K.Miyano,H.Shimonaka,M.Kanai,N.Ueba,N.Kunita and T.Kurimura*
Osaka Prefectural Institute of Public Health,Osaka,Japan,
* Tottori University, School of Medicine, Yonago,Tottori,Japan.

Amphotericin,B methyl ester(AME),a water-soluble derivative of amphotericin B, showed inhibitory effect on HIV. However,the cytotoxicity of AME was relatively high. Newly synthesized sulfated amphotericin B(SA), which was expected to show low toxicity and anti-HIV effect, was examined in vitro.

SA at the concentration of 8μg/ml completely suppressed the HIV-induced cytopathic effect in MT-4 cell line which carried HTLV-Ⅰ. Furthermore, antiviral effect was also observed when SA was only present at absorption period of HIV. Proliferation of HIV was also suppressed in peripheral blood mononuclear cells(PBMC) infected with freshly isolated HIV. The cytotoxicity of SA was low (50% cytotoxic dose for MT-4 cells and PBMC was 2mg/ml). When MOLT-4 and MOLT-4/HIV cells were co-cultured, multinucleated giant cells appeared. At the concentration of SA more than 30μg/ml, the formation of giant cells was inhibited. SA at the concentration of 200μg/ml inhibited 80% of reverse transcriptase activity of HIV.HIV was exposed to SA for 2h. At concentration of 20μg/ml, SA reduced infectivity of HIV to 1/10.

These anti-HIV effect of SA was considerd to be caused by the inhibition of HIV binding to the cells and reduction of infectivity of HIV.

M.C.P.80 INHIBITION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) REPLICATION BY SYNTHETIC OLIGO-DNA DERIVATIVES

Agrawal, Sudhir*; Sun, D.**; Sarin, P.S.**; Zamecnik, P.C.*
*Worcester Foundation for Experimental Biology, Shrewsbury, Mass.
**Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Md. U.S.A.

A number of approaches are currently being investigated for treatment of human immunodeficiency virus (HIV) infected patients with acquired immunodeficiency syndrome (AIDS). We have used antisense oligonucleotides to selectively block virus replication by competitive hybridization (Zamecnik et al., PNAS 75:280, 1978). We have investigated three classes of phosphate backbone modified oligodeoxynucleotides viz. methylphosphonate, phosphorothioate and various phosphoramidates for their antiviral activity. The inhibition of HIV-1 expression in presence of antisense oligonucleotides was carried out by infecting H9 or MOLT-3 cells with HIV-1 (HTLV-III$_B$ or HTLV-III$_{cc}$). Studies were carried out by simultaneous addition of virus and antisense oligonucleotides to cells in culture. After four days, the cells and supernatants were examined for the level of HIV expression by counting syncytia (MOLT-3 cells), viral antigens expression and cell viability. The sequences tested were complementary to splice acceptor and donor sites of HIV RNA. Inhibition of up to 100% of HIV-1 replication was observed at 3 to 5 μM concentration of these oligonucleotides. Acute toxicity studies in mice and rats show a relatively low level of toxicity. These studies suggest that phosphate backbone analogs of oligonucleotides are potent inhibitors of HIV-1 replication and could be potentially useful in the treatment of AIDS.

M.C.P.81 ASSESSMENT OF THE THERAPEUTIC ACTIVITY OF PHOSPHONYLMETHOXYETHYL ADENINE (PMEA) AND AZIDOTHYMIDINE (AZT) IN A MURINE MODEL OF ACQUIRED IMMUNODEFICIENCY DISEASE

J. David Gangemi*; Robert M. Cozens**; Erik De Clercq***; Alex Matter**; & Heinz-Kurt Hochkeppel**; *University of South Carolina, Columbia, SC, USA; ***CIBA-GEIGY, Basel, Switzerland;***Katholieke Universiteit, Leuven,Belgium.

The murine model of acquired immunodeficiency disease (MAIDS) was used to evaluate the therapeutic potential of two nucleoside analogues, phosphonylmethoxyethyl adenine (PMEA) and azidothymidine (AZT). The antiviral activity of PMEA was compared to AZT in mice receiving drug either immediately following infection or at later times in disease progression. Both AZT (oral, 30 mg/kg) and PMEA (parenteral, 25 mg/kg) were effective in preventing the development of disease when administered daily beginning on the day of infection. In contrast, neither drug alone was effective in modifying disease outcome when administered several weeks after viral infection. This was not, however, the case when alpha interferon was used in combination with PMEA. Disease outcome was modified when infected mice were put on a continous regimen of PMEA (25 mg/kg) and alpha interferon (5×10^7 U/kg).

A number of humoral and cellular immune functions were severly depressed 60 days after LP-BM5 infection. Immunocompromised mice were highly susceptible to acute (lethal) infection with HSV-1, while age-matched immunocompetent littermates were not. PMEA was as effective as acyclovir in the treatment of HSV-1 infections in immunosuppressed mice. The data suggest that the in vivo antiretroviral activity of PMEA is comparable to AZT. An important advantage of PMEA is its usefulness in the therapy of opportunistic herpesviral infections.

M.C.P.82 INHIBITION OF HIV REPLICATION BY ALPHA INTERFERON

Smith, Marilyn S., Brian, E., Thresher, R., Pagano, J.S. Univ. of N.C., Chapel Hill, NC, USA

Objective. To investigate the mechanism of inhibition of HIV replication by interferon alpha in vitro.

Methods. T cells were infected with HIV and treated with Wellferon; or chronic producing cells were treated with Wellferon. Virus production was assayed by reverse transcriptase activity and p24 concentration. Cellular extracts were assayed by western blot and p24 ELISA; cells were examined by electron microscopy.

Results. In the C3 line , the EC_{50} was 5.5 U/ml, and EC_{90} was 274 U/ml. We attempted to determine if high concentrations of intracellular particles were accumulating by assaying extracellular RT and p24 levels, the intracellular p24 and viral protein levels, or by EM. In cells treated with IFN, the RT and p24 levels decreased proportionally, whereas the intracellular p24 levels remained nearly constant. Western blots of cellular protein showed only at most a 2X decrease in viral proteins; the amount of processing of precursor to p24 and p17 did not change in the presence of interferon. By EM, the cells treated with 512 U/ml showed almost no virus budding into extracellular spaces; however, no intracellular particles could be seen.

Conclusion. Thus, inhibition of this human retrovirus by alpha interferon does not appear to involve decreased processing of viral proteins or intracellular core formation.

M.C.P.83 EXPERIMENTAL AZIDOTHYMIDINE (AZT) PULSE THERAPY LEADS TO ADEQUATE AND PROLONGED LEVELS OF INTRACELLULAR AZT-TRIPHOSPHATE (AZT-TP)

Vogt, Markus; Kuster, H.; Nadai, V.; Joos, B.; Siegenthaler, W. and Lüthy, R.
Division of Infectious Diseases, Dept. of Medicine, University Hospital, Zurich, Switzerland

Objective. Our earlier studies showed that single daily AZT pulse exposure effectively inhibits HIV-1 and HIV-2 replication in vitro. We have now evaluated intracellular AZT anabolism both in pulse and continuous therapy schedules.

Methods. Based on earlier dose finding studies using a newly developed in vitro model, duplicate cultures with peripheral blood mononuclear cells were either exposed to 10 uM AZT (+45 uCi/nmol ^{3}H-AZT) for 60 min. or to 1 uM AZT (+^{3}H-AZT) for one day. After 24 hr in culture, cellular extracts were analyzed by paired ion HPLC, and radioactivity was assayed by liquid scintillation counting. Furthermore, hypothetical simulation of human AZT plasma levels after a single daily oral dose of 1 g AZT was performed using a computer model (Burroughs Wellcome, UK).

Results.

Treatment		Azidothymidine (pmol/10^6 cells) Monophosphate	Diphosphate	Triphosphate
24h	1 uM AZT	33	0.4	0.9
1h	10 uM AZT	18	1.0	2.0

Mathematical simulation of a single oral dose of 1 g revealed plasma levels of 10 uM or higher for 60 min.

Conclusions. Single day in vitro pulse therapy leads to adequate intracellular levels of AZT-TP thus explaining the observed anti-HIV effect of this regimen. The effect of a single daily oral dose of 1 g should be exploited in clinical trials.

M.C.P.84 EXPRESSION OF AUTHENTIC AND ENZYMATICALLY ACTIVE HIV1 AND HIV2 PROTEASES IN *SACCHAROMYCES CEREVISIAE*.

Pichuantes, Sergio*; Babe, L.*; Barr, P.** and Craik, C.*
*University of California, Department of Pharmaceutical Chemistry, San Francisco, California.
**Chiron Corporation, Emeryville, California, USA

Genetic analysis of the HIV genome has revealed a 99 amino acid protease encoded at the 5' end of the *pol* gene which is essential for the processing of *gag* and *gag/pol* polyprotein precursors. The proteases encoded by the HIV1 and HIV2 genomes are 47.5% identical in their amino acid sequences. Functional and structural studies of these viral proteins require reagent quantity levels of the authentic enzyme which can be achieved by heterologous expression of the cloned gene. An expression system employing the ADH2/GAPDH promoter was used to overexpress both retroviral proteases intracellularly and extracellularly in yeast. For external localization of the enzymes, two different DNA fragments were fused to DNA encoding the *S. cerevisiae* alpha factor signal/leader sequence. These viral fragments encode either the mature 99 amino acid protease or a precursor containing additional residues at the N and C termini of the protease in order to monitor self-processing. For internal localization, retroviral sequences encoding the protease were fused to the C-terminus of human superoxide dismutase. Expression of mature HIV1 and HIV2 proteases was demonstrated for all systems by immunodetection in yeast supernatants or cellular extracts. Self-processing activity was confirmed by amino acid sequence analysis of the mature enzyme. The HIV1 protease has been purified and structural studies have been initiated. Extracellular localization of the protease has permitted rapid purification to homo-geneity using a two step purification scheme. From 20 liters of media 1 mg of protein can be purified. This protease is active on both native and synthetic peptide substrates. Both the HIV1 and the HIV2 protease correctly process HIV1 *gag* polyprotein precursor. Results indicate that yeast cells provide an efficient expression system for the overproduction of active forms of HIV1 and HIV2 proteases.

M.C.P.85 IMMUNOLOGIC EFFECT AFTER SINGLE DOSE ATVOGEN (AMPLIGEN) IN HEALTHY VOLUNTEERS

Hendrix, Craig; Lietman, P.; Ts'o, P.; Margolick, J.; Farzadegan, H; Petty, B. Johns Hopkins University, Schools of Medicine and Hygiene and Public Health, Baltimore, Maryland, U.S.A.

Objective. To evaluate the degree and time course of immunologic stimulation after a single 200 mg intravenous (i.v.) dose of atvogen, a mismatched double-stranded RNA, in healthy volunteers.
Methods. This was a randomized, double-blind, inpatient study in four healthy volunteers. Subjects served as their own controls, randomized to one of two treatment sequences, atvogen or placebo followed 7 days later by placebo or atvogen. We measured α- and γ-interferon, 2'-5' oligoadenylate synthetase (25AS), neopterin, T cell subsets (CD3, CD4, CD8, Leu7, Leu 11, Leu 19), natural killer cell (NK) activity and lymphocyte proliferation (LP) after exposure to soluble antigens (CMV, tetanus toxoid, pokeweed mitogen).
Results. No symptomatic, clinical or laboratory changes were noted in either drug or placebo periods. Neither α- or γ-interferon were measurable during the 5 days following atvogen infusion. Biochemical markers of interferon action, specifically 25AS and neopterin, and T cell subsets were not significantly different after atvogen dosing compared to placebo. Neither the NK nor LP assays showed any differences in response between atvogen or placebo treatments.
Conclusions. Atvogen induces no immunologic enhancement in the parameters measured after a single 200 mg i.v. dose in healthy volunteers.

M.C.P.87 THE ANTIVIRAL EFFECT OF DEXTRAN SULFATE (DXS) IS HIV STRAIN DEPENDENT

Resnick, Lionel* and Busso, M. E.*
*Mount Sinai Medical Center, Miami Beach, Florida, USA.

Objective. To study the anti-HIV activity of DXS using different isolates.
Methods. The anti-HIV effects of DXS (8K, 40K, 500K) were investigated using a syncytium-inhibition (MT-2 cell) assay. The peripheral blood HIV strains studied were: HIV-1 [IIIB (lab strain), TM (wild-type), WMF 3D (clone)] and HIV-2 [ROD (clone)]. Syncytium-forming units, cell viability, and IIF (cellular p24 Ag) were utilized as measures of HIV expression. The input concentration of HIV was standardized by limiting dilution and sensitivity to AZT. Combinational effects of DXS and ddNUs (AZT, ddA, ddC) were analyzed and a fractional inhibitory index calculated.
Results. The higher the MW of DXS, the more potent the anti-HIV effect. The ID50 was greater than 1mg/ml for all DXS. The ED50 of DXS was HIV strain dependent [ED50 (ug/ml) range: IIIB (5-22), TM (56-360), WMF 3D (18-62), ROD (17-45)]. The anti-HIV effects of DXS (8K) and ddNUs were synergistic. However, the combination of DXS (500K) and ddNUs were synergistic (therapeutic range of DXS) or antagonistic (sub-therapeutic range of DXS) when using HIV-1 TM.
Conclusion. The anti-HIV activity of DXS is strain and MW dependent. The combination of DXS and ddNUs may yield synergistic/antagonistic effects. (Supported by IVAX Corp. and NIH UO1-AI25696).

M.C.P.89 EXPRESSION AND CHARACTERIZATION OF CHIMERIC PROTEINS CONTAINING HUMAN CD4 LINKED TO HUMAN IMMUNOGLOBULIN HEAVY CHAIN CONSTANT REGIONS

Mizukami, Tamio, Smith, C.D., Berger, E.A. and Moss, B.
Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD 20892, USA

Objective. To express and characterize the properties of chimeric proteins composed of human CD4 and human immunoglobulin G (IgG) heavy chain constant regions for the potential therapeutic use of these proteins as new targeted anti-HIV agents.
Methods. The chimeric proteins were produced using a vaccinia virus-based expression system and tested for the binding properties to various ligands and antibodies against each domain.
Results. Three types of chimeric proteins with different lengths (1-109, 1-178, and 1-372) of the CD4 extracellular region linked to human IgG1 heavy chain constant regions were designed and expressed in CV-1 and RPMI8226, a human myeloma cell line secreting a Ig light (lambda) chain. The chimeric proteins expressed in both cell lines bound to the HIV-1 gp120, OKT4A (anti-CD4), an anti-human IgG(Fc) polyclonal antibody, and Protein A-agarose. The chimeric proteins which were expressed in RPMI8226 formed complexes with the lambda chain synthesized by the host cell line.
Conclusion. The CD4-IgG1 chimeric proteins had the expected binding properties of the domains used for their construction. The chimeric proteins when co-expressed with human Ig light chains formed complexes which might have structures analogous to that of natural immunoglobulin molecules.

M.C.P.86 STUDIES ON ANTI-HIV ACTIVITY AND METABOLISM OF 2',3'-DIDEOXYGUANOSINE (ddG)

Resnick, Lionel*; Busso, M. E.*; and Mian, M. A.**
*Mount Sinai Medical Center, Miami Beach, Florida, USA, ** Sylvester Comprehensive Center, University of Miami, Miami, Florida, USA.

Objective. To study the anti-HIV activity and metabolism of ddG.
Methods. The anti-HIV activity of ddG was determined by a syncytium-inhibition assay using MT-2 cells and by the inhibition of reverse transcriptase activity in H9 HIV-infected cells. In drug uptake studies, cells were exposed to [3H]ddG for predetermined periods. Cells were isolated by centrifugation through an oil layer and the intracellular radioactivity was determined. In metabolism studies, drug treated cells were extracted with aqueous methanol and the extracts were analyzed by anion exchange and C18 reverse phase HPLC procedures.
Results and Conclusions. Data indicate that ddG is equipotent to ddA or ddI in its anti-HIV activity. Guanosine and dGuo did not reverse the anti-HIV activity of ddG, whereas 8-aminoGuo failed to enhance. In drug exposed cells, the intracellular radioactivity increased over time and reached a plateau at 5 minutes. Addition of an excess of Guo or dGuo reduced the uptake of ddG by 25-40%. Metabolic studies indicate that ddG enters the cell and is catabolized to guanine which is further anabolized to GMP, GDP, and GTP. Under the experimental conditions employed, we were unable to detect the formation of [3H]ddGTP. These observations raise the question regarding the importance of this metabolite's role in the anti-HIV activity of ddG. (Supported by IVAX Corp. and NIH UO1-AI25696).

M.C.P.88 IN VITRO ACTIVITY OF RIBAVIRIN IN ACUTE AND COCULTIVATED HIV INFECTION OF HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS

Roberts, Richard B.; Cornell University Medical College, New York, NY, USA.

Objective. To determine if ribavirin inhibits HIV replication in vitro in acutely infected normal or cocultivated patients PBMC.
Methods. Acute infection: PHA-stimulated normal donor PBMC ($1x10^6$cells/ml) were pretreated with ribavirin (2,10,20,40ug) or ddC(0.02,0.2,2.0,4.0ug) x 18 hours in IL-2 medium and then infected with HIV. Cocultivated infection: HIV-infected PBMC from 5 patients were cocultivated with PHA-stimulated normal donor PBMC pretreated with either drug x 18 hours in IL-2 medium. Assays for antigen capture (ELISA) and cell viability (MTT) were performed either daily or at days 3-4, 7 and 9-12.
Results. Acute infection: Maximum antigen concentrations (MAC) were achieved by day 5 in culture whereas 39 and 84% of MAC occurred at day 3 and 4 respectively. Virus inhibition (%VI) and cell viability (%CV) at various days in culture were as follows:

		day 3		day 4		day 7		day 10	
Drug (ug/ml)		%VI	%CV	%VI	%CV	%VI	%CV	%VI	%CV
Ribavirin	2	15	87	13	—	0	69	7	72
	10	34	100	36	—	0	69	7	80
	20	62	97	58	—	0	60	6	84
	40	71	86	72	—	2	59	7	67
ddC	0.02	40	93	55	—	2	98	4	100
	0.2	68	100	84	—	73	100	67	100
	2.0	80	100	95	—	94	86	91	100
	4.0	82	93	91	—	90	91	93	100

Cocultivated infection: Mean days to first positive culture in cocultures with no drug was 5.6 days compared to 5.6 and 7.0 days in cocultures containing 20 and 40ug ribavirin respectively. Cocultures remained negative for greater than 17 days in the presence of 2ug ddC.
Conclusions. When compared to ddC the in vitro activity of ribavirin in acutely infected human PBMC was only partial at high doses and was absent in cocultivated PBMC.

M.C.P.90 ANALOGS OF 3'AMINO-3'DEOXYADENOSINE INHIBIT HIV-1 REPLICATION

Lee Ratner*, M Vander Heyden*, and C Rodi^. *Department of Medicine, Washington University, ^Biological Sciences Department, Monsanto, St. Louis, Mo., USA

Objective: Several different nucleoside analogs have been demonstrated to inhibit retroviral RNA-dependent DNA polymerase activity in preference to cellular DNA-dependent DNA polymerases. This study analyzed the anti-HIV-1 activity and host cell toxicity of 3'amino deriviatives of 3'deoxyadenosine.
Results: Puromycin aminonucleoside (PANS), PANS 5'monophosphate, and 3'amino-3'deoxyadenosine triphosphate all inhibited HIV-1 replication in acutely infected cells at concentrations at least 10-fold lower than those which inhibited cell growth. No antiviral effects were seen with N6-dimethyl adenosine, adenosine, or puromycin. In chronically infected cells, no antiviral activity of PANS could be detected. The effect of PANS was demonstrated at an early step in HIV-1 replication, most likely reverse transcription.
Conclusions: 3'Amino nucleoside analogs are a novel class of inhibitors of HIV-1 replication which require further analysis in cell culture and animal studies.

M.C.P.91

SULFATED SUGARS INHIBIT HIV. Myra McClure*, Denise Whitby*, Rachanee Cheingsong-Popov**, Jonathan Weber**, Donald Davies**, and Robin A. Weiss*. *Institute of Cancer Research, Fulham Road, London UK; **Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 ONS, UNITED KINGDOM

Objectives: To test sulfated polysaccharides for evidence of antiviral activity.

Methods: The effect of drugs on HIV infection was assessed by syncytium formation, RT and p24 antigen synthesis on lymphocytic and monocytic cells and on CD4-transfected HeLa cells.

Results: The compounds will be defined and data presented to show that:

(a) The degree of sulfation is important for antiviral function.

(b) Two compounds, one of which has been newly synthesised, inhibit by 10,000 fold on the C8166 infectivity assay a wide range of HIV-1 isolates.

(c) HIV-2 was inhibited by one compound, but not as strongly.

(d) There is low cellular toxicity and no adverse effect on protein metabolism or T-cell function.

(e) The drugs themselves appear to have a mitogenic effect on PBL.

M.C.P.92

CSF FROM PATIENTS WITH EARLY HIV INFECTION PRODUCES NEURONAL CELL KILLING IN VITRO: PREVENTION BY PEPTIDE T

Buzy , J.M.*, Brenneman, D.E.#, Salazar, A., Martin, A. Ruff , M.R.* and Pert, Candace*
NICHD#, NIMH, Bethesda, MD and Walter Reed Army Medical Center, Washington, D.C., U.S.A.

Objective: To test for the presence of gp120-like neuronal killing activity in CSF from seropositive patients and the ability of peptide T to prevent CSF- induced neurotoxicity.
Method: Twenty-eight cerebrospinal-fluid samples from neurological controls and HIV-infected individuals were tested (blind to the investigator) in murine hippocampal cultures. HIV+ individuals had been referred for neuropsychological evaluation and 83% were in Walter Reed Stages 1-3. All individuals received a comprehensive neuropsychological and neurological evaluation at the time of the spinal tap and 6 months later. CSF samples were diluted 100,000-fold and incubated for five days in the presence and absence of peptide T. Previous studies have shown that the envelope protein of the HIV, gp-120, is potently neurotoxic in this developing neuronal culture. VIP neuropeptide, peptide T and monoclonal antibodies against mouse CD4, prevented gp120-induced neuronal cell death (Brenneman et al. *Nature* 335:639-42, 1988).
Results: CSF from 9 out of 18 HIV-infected individuals showed significant (>20% of control) *in vitro* neuronal killing activity which was blocked by peptide T. Only one multiple sclerosis case out of 10 neurological controls had significant neuronal killing .
Conclusion: The ability of CSF to potently kill neurons in culture is associated with HIV+ individuals. Peptide T prevented CSF-induced toxicity *in vitro*. These data are consistent with our previous suggestion (Brenneman et al. *Drug Development Research* 15:361-369, 1988) of the causal role of gp120 in neuropsychiatric/neurological deficits of HIV.

M.C.P.93

SYNTHESES OF NEW SUGAR-FLUORINATED GUANOSINE ANALOGUES AS POTENTIAL ANTI-HIV AGENTS

Puech, F.*; Gosselin, G.*, De Clercq, E.**, Imbach, J-L.*
* UA 488 du CNRS, USTL, 34060 Montpellier Cédex 1, France
** Katholieke Universiteit, Leuven, Belgium

Presented by Guedj, Roger, Université de Nice, France

Objective. Purine nucleosides fluorinated in the sugar moiety have been not very investigated owing to the difficulty in their synthesis. Here we report the synthesis of hitherto unknown fluorinated analogues of guanosine and their evaluation as potential anti-HIV agents.
Methods. The synthesis of 9-(3-deoxy- and 2,3-dideoxy-3-fluoro--β-D-xylofuranosyl)guanine (1) and (2) was accomplished by a multi-step approach involving prior preparation of a suitably protected fluorosugar. 3'-Deoxy-3'-fluoroguanosine (3) was prepared by reacting the corresponding nucleoside of *xylo* configuration with (diethylamino)sulfurtrifluoride. *The* mixture of 9-(3-deoxy-3-fluoro-β-arabinofuranosyl)guanine (4) and 9-(2--deoxy-2-fluoro-β-D-xylofuranosyl)guanine (5) was obtained by ring opening of the lyxo epoxide of guanosine.
Results. The compounds 1-5 were evaluated in HIV infected MT4 cells. Only the mixture of 4 and 5 was found to inhibit significantly viral replication.

M.C.P.94

POPULATION PHARMACOKINETIC BEHAVIOR OF ZIDOVUDINE (AZT) IN PATIENTS WITH ARC.

S.Gitterman, George L. Drusano, M.Egorin, H.Standiford and the Participating Centers for VACSP Trial#298. University of Maryland and the VA Coperative Studies Program, Baltimore, Md. and West Haven, Conn., USA.

There is little published information on the disposition of AZT. That which is available has been generated in populations of patients with AIDS. Past experience with other compounds has shown that the disposition of a drug is often changed dramatically by the disease status of the population in which it is administered. As we were performing a large, multicentered, randomized, double blind evaluation of AZT in patients with ARC with >200 and <500 CD4 cells, we decided to evaluate the pharmacokinetics of AZT in this population. Blood was obtained for AZT assay on a scheduled and random basis from all study participants, maintaining the blind. Serum AZT concentration was determined by HPLC. Seventy-seven patients had more than one serum specimen with assayable AZT, with a total of 277 specimens suitable for analysis. In order to deal with this information in the most mathematically correct fashion, point estimates of population pharmacokinetic parameters were sought using the program NONMEM (non-linear mixed effects modelling). A one compartment open model with first order absorption and first order elimination from the central compartment was employed. Total Clearance (TC), Volume of Distribution (V) and Absorption Rate Constant (Ka) were the estimated parameters. A proportional error model was employed for all identified parameters. Mean (SE) TC for the population was 142 (9) L/h/70kg. Corrected for a bioavailability (F) of 0.63, this value becomes 89.5 L/h/70kg, identical to the value obtained in patients with AIDS. Mean (SE) V was 342 (23) L/70kg, a value much larger than that identified in AIDS patients, even when corrected for F (215 L/70kg). The Ka was very large, with a broad 95% confidence interval, implying rapid absorption, but poor parameter identifiability. Estimates of intraindividual variation (eta) were not robust, but did not impact on the estimation of the system parameters above. The population approach worked well in this patient care situation. The larger volume of distribution noted is probably a function of studying healthier patients with larger lean body masses. More importantly, because it is extremely difficult to obtain good pharmacologic information on drug disposition in the clinical setting (AZT Phase I trials typically enrolled only 3-5 patients /dose level), the population modelling approach needs to be more broadly employed as newer agents for therapy of HIV and HIV-related disease are evaluated.

M.C.P.95

ANTI-RETROVIRAL ACTIVITY OF AN AQUEOUS EXTRACT OF HYDROCOTYLE ASIATICA

Arnold B. Rabson*, Flatow, U.**, Krutzsch, H.**, Kinter, A.*,and Hoggan,M.D.*.
* NIAID, ** NCI, NIH, Bethesda, Md. USA.

Objective. To study the anti-retroviral effect of an aqueous extract of the Indian Ayurvedic medicinal plant, Hydrocotyle asiatica.
Methods. An aqueous extract of dried powdered Hydrocotyle asiatica (HA) was prepared by vortexing followed by sterile filtration . HA extract was diluted 1:200 to 1:800 by addition to tissue culture medium. The effects of HA on HIV-1 infection were studied by use of a syncytia formation assay in SupT1 cells, plaque formation in MT4 cells and kinetics of virion production and cytotoxicity in MT4 cells and PBLs. The effects on murine leukemia viruses (MuLVs) were studied for MoMuLV and HaSV in NIH 3T3 cells .Viral yield was assayed by determination of reverse transcriptase production, and for HaSV, production of focus-forming units (ffu).
Results. A 1:200 dilution of HA resulted in a greater that 90% reduction in HIV-1 induced syncytia formation in SupT1 cells and a similar inhibition of plaque formation in MT4 cells. In suspension cultures, HA treatment resulted in a 2-3 day delay in the appearance of HIV induced cytopathic effect and cell death in MT4 cells. No comparable delay of cytotoxicity was observed in PBLs. In studies of MuLV infection, HA resulted in an 85-95% decrease in viral yield as monitored by RT production and similar decreases in the production of HaSV ffu. Studies of the mechanism of anti-viral effect in the MuLV system showed that HA was not directly virucidal and did not inhibit virus adsorption. Pretreatment of cells followed by removal of HA did not inhibit MuLV suggesting that HA was not acting as an interferon inducer.
Conclusions. An aqueous extract of Hydrocotyle asiatica appeared to inhibit the replication of HIV-1 and MuLVs in several different assay systems. The degree of anti-HIV effect varied in different cell types thus further mechanistic studies and biochemical characterization of active components will be required before its potential usefulness can be ascertained.

M.C.P.96

ACTIVATION OF THE ANTI-HIV AGENT 2',3'-DIDEOXY-2',3'-DIDEHYDROTHYMIDINE (D4T) BY HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) IN CULTURE.

Hsu-Tso Ho, H. Yang and M.J.M. Hitchcock.
Bristol-Myers Pharmaceutical Research and Development Division, Wallingford, Connecticut, U.S.A.

Objective. To compare metabolism of D4T with AZT in resting and phytohemagglutinin (PHA)-activated human PBMC.
Methods. PBMC were prepared by sedimentation of fresh whole blood in a LeucoPREP cell separation tube. PHA-stimulation (5 µg/ml) was for 72 h, and the PHA was then washed out. After incubation with 2 µM radiolabeled D4T or AZT, cells were washed and extracted with 60 % methanol, and the extracts were fractionated by anion exchange HPLC.
Results. In resting PBMC incubated with 2 µM compound for either 24 or 48 h, cell-associated D4T and AZT were both detected at close to the extracellular concentration, but no phosphorylated forms of either compound were observed (detection limits of 1 and 20 nM for D4T and AZT, respectively). In activated PBMC at 24 h, 55 % of the phosphorylated D4T was present as the triphosphate. Its intracellular concentration was estimated at 100 nM, which is above the Ki for HIV reverse transcriptase. By contrast, the only phosphorylated form of AZT detected was the monophosphate (about 27,000 nM) and the di- and triphosphates were below the limit of detection (20 nM).
Conclusion. These results demonstrate a significant difference between the metabolism of D4T and AZT in stimulated PBMC. This may translate to a different, and possibly better, toxicity profile in vivo.

M.C.P.97 THREE DRUG SYNERGISTIC INHIBITION OF HIV-1 REPLICATION BY RECOMBINANT SOLUBLE CD4 (rsT4), ZIDOVUDINE (AZT), AND RECOMBINANT INTERFERON-ALPHA-A (rIFN-α-A).

Johnson, Victoria A*; Barlow, MA*; Chou, TC**; Merrill, DP*; Hirsch, MS*.
*Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA;
**Memorial Sloan-Kettering Cancer Center, NY, NY, USA.

Objective. To assess the interactions of rsT4, AZT, and rIFN-α-A in combination against HIV-1 replication in vitro.
Methods. We evaluated rsT4 (a soluble viral receptor) in combination with AZT (a reverse transcriptase-RT-inhibitor) and rIFN-α-A (an agent which may affect viral assembly and release). H9 cells were exposed simultaneously to HIV-1 and various concentrations of each agent, either alone or in 2- or 3-drug combinations. Drug interactions were evaluated by the median-effect principle and the isobologram technique.
Results. HIV-1 p24 antigen production (ng/ml) on days 10-11:

Expt. no.	Inf. Control	rsT4 0.08 µg/ml	AZT 0.64 µM	rIFN-α-A 32 U/ml	2-Drug Combinations			3-Drug Combination
					rsT4 & AZT	AZT & rIFN-α-A	rsT4 & rIFN-α-A	
1	2935	2780	2790	1980	1690	620	426	123
2	2130	326	1890	460	87	52	60	21

Similar results were obtained at different times and by utilizing other assays (RT activity and virus yield).
Conclusion. Combinations of rsT4 (0.02-0.32 µg/ml), AZT (0.16-2.56 µM), and rIFN-α-A (8-128 U/ml), as 2- or 3-drug combinations, inhibited HIV-1 synergistically. The 3-drug regimen provided more complete suppression than the 2-drug regimens without additive toxicity in vitro.

M.C.P.99 DIFFERENTIAL SENSITIVITY OF BONE MARROW DNA POLYMERASES ALPHA AND DELTA TO INHIBITION BY DIDEOXYNUCLEOTIDES

Byrnes, John J., University of Miami School of Medicine, Miami, Florida, U.S.A.

Objective: To examine the sensitivity of bone marrow DNA polymerases alpha and delta to inhibition by dideoxynucleotides.
Methods: DNA polymerases were highly purified from rabbit bone marrow as previously described. Standard DNA polymerase assays using either activated DNA or synthetic primer/template combinations and different reaction conditions were used to examine the effect of ddCTP and ddTTP.
Results: Under conditions of magnesium activation DNA polymerase alpha was resistant up to 200 uM ddNTP, however DNA polymerase delta was 50% inhibited at 80 uM of either ddCTP or ddTTP. Under conditions of manganese activation alpha and delta were both 50% inhibited by 5 uM ddNTP. Kinetic analysis demonstrated a competitive pattern with respect to the corresponding dNTP. Activity of the 3' to 5' exonuclease associated with delta did not alleviate the inhibitory effect of the ddNTP.
Conclusions: The sensitivity of DNA polymerase delta under conditions of magnesium activation may have bearing on the bone marrow toxic effect of ddNTPs. Both DNA polymerases are believed to function in DNA replication and current evidence suggests a coordinate action of delta synthesizing the leading strand and alpha the lagging strand. Relatively minor inhibition of DNA polymerase delta may uncoordinate cellular DNA replication.

M.C.P.101 RANDOMIZED PHASE II TRIAL OF RECOMBINANT TUMOR NECROSIS FACTOR (rTNF) AND RECOMBINANT INTERFERON-GAMMA (rIFN-GAMMA) IN PATIENTS WITH ARC

Agosti JM*, Coombs R*, Kidd PG*, Paradise M*, Sherwin S**, Corey L*.
*University of Washington, Seattle, WA; Genentech, Inc., San Francisco, CA., U.S.A.

Objective: To determine if TNF worsens or decreases the progression of HIV infection.

Methods: While some have reported that TNF inhibits HIV replication others have reported enhanced replication in chronically infected cells treated with TNF. To evaluate this we randomly assigned 30 patients with ARC to receive either TNF only (10 mcg/m^2), IFN-gamma (10 mcg/m^2) + TNF (10 mcg/m^2), or IFN-gamma only (10 mcg/m^2) for a 16 week period. Data available on 16 patients indicate the following: side effects included fever (100%), grade I mild constitutional symptoms (100%), and local reactions (100%). No significant hematologic, hepatic, renal, or coagulation abnormalities were observed and only one patient discontinued therapy because of side effects. T cell subset determination did not change significantly during therapy. HIV was isolated from peripheral blood lymphocytes (PBLs) in all patients prior to therapy while none became persistently negative, the frequency of HIV isolates from PBLs decreased from 92% before therapy to 84% during therapy. Plasma viremia was 56% prior to therapy and decreased to 29% during therapy.

Conclusion: This study demonstrates that TNF alone or in combination with IFN-gamma does not appear to hasten the progression of HIV infection either clinically or virologically. Further studies are required to determine if either of these compounds alone or together have biologic in vivo antiviral activity.

M.C.P.98 COMPARATIVE PHARMACOKINETICS OF 3'-AZIDO-2',3'-DIDEOXYURIDINE (AZddU) AND 3'-AZIDO-3'-DEOXYTHYMIDINE (AZT) IN MONKEYS

Boudinot, F. Douglas*; Schinazi, R. F.**; Gallo, J.M.*; McClure, H.***; Anderson, D.***; Chu, C.K.*.
*College of Pharmacy, University of Georgia, Athens, Georgia, USA, **Veterans Administration Medical Center and Emory University, Atlanta, Georgia, USA ***Yerkes Primate Center, Emory University, Atlanta, Georgia, USA.

Objective. To characterize and compare the pharmacokinetics and bioavailability of AZddU and AZT in uninfected rhesus monkeys.
Methods. Monkeys were administered AZddU or AZT as follows; 60 mg/kg intravenously, 60 mg/kg orally, 200 mg/kg orally and 33 mg/kg subcutaneously. Serial blood samples were obtained. Cerebrospinal fluid and urine samples were taken 1h after dosing. Nucleosides were assayed by HPLC.
Results. After AZddU total clearance averaged 0.91± 0.051 L/h/kg and volume of distribution was 0.89± 0.14 L/kg. After AZT total clearance and volume of distribution were 1.57 L/h/kg and 1.07 L/kg, respectively. Oral absorption of AZddU and AZT was virtually complete (F> 0.90) after 60 mg/kg, however, bioavailability of both nucleosides was markedly lower (F< 0.50) after 200 mg/kg. The nucleosides appeared to be well absorbed after subcutaneous administration. AZddU and AZT penetrate the cerebrospinal fluid with CSF: serum concentration ratios ranging between 0.05-0.25 1h after drug administration.
Conclusion. The similar pharmacokinetic characteristics and lower toxicity of AZddU compared to AZT suggest that clinical trials of AZddU are warranted.

M.C.P.100 RECOMBINANT GRANULOCYTE COLONY STIMULATING FACTOR (r-metHuG-CSF) INCREASES NEUTROPHIL NUMBER AND FUNCTION BUT DOES NOT ALTER HIV EXPRESSION IN PATIENTS WITH AIDS.

Miles, Steven*; Glaspy, J.*; Chung, Y.*; Lee, K.*; Souza, L** and Baldwin G.*. *UCLA AIDS Center, Los Angeles, CA., USA and **Amgen, Inc. Thousand Oaks, CA., USA.

Objective. To see if r-metHuG-CSF can improve neutrophil function and number in AIDS patients without altering HIV expression.
Methods. Phase I/II Open Label Trial of r-metHuG-CSF/r-HuEPO/AZT in patients with AIDS/severe ARC. Patients with absolute neutrophil counts (ANC)< 2500/mm^3 and hemoglobin (Hb)< 11.5 gm/dl (off all marrow suppressive drugs including AZT > 3 weeks) were treated with r-metHuG-CSF once daily at 3 mcg./kg subQ until an ANC of >6000 was achieved and maintained for 2 weeks.
Results. Eleven of 24 planned patients have been enrolled. Eight have reached >6000 ANC, maintained for >2 weeks and are evaluable. The other 3 patients have reached >6000 ANC but have not been on >2 weeks.

	Pre G-CSF	Post G-CSF	P value
Absolute Neutrophils	1021 ± 600	21,470 ± 9130	< 0.001
Total WBC	1875 ± 790	23,600 ± 9115	< 0.001
CD4 cell number	10.4 ± 6.3	22.8 ± 14.7	< 0.05
HIV p24 antigen	225 ± 454	247 ± 391	> 0.05

With one exception, normal neutrophil function (S.aureus phagocytosis and intracellular killing) was observed in all pts. before and during r-metHuG-CSF. One pt. had a discrete intracellular killing defect which normalized on r-metHuG-CSF. Analysis of limiting dilution plasma and lymphocyte cocultures showed no significant alterations in viral expression.
Conclusions. r-metHuG-CSF significantly increases neutrophil number and function in AIDS patients without altering HIV expression. r-metHuG-CSF shows promise in abrogating the neutropenia of AIDS.

M.C.P.102 A LONG-LIVED CD4 CARRIER IN CIRCULATION. RED BLOOD CELLS WITH CD4 RECEPTORS INSERTED IN THEIR MEMBRANE.

Arvinte, Tudor*; Cudd, A.*; Schulz, B.*, and Nicolau, C.*,**.
*Biophor Corporation, College Station, Texas, USA, and **Baylor College of Medicine, Houston, Texas, USA.

The CD4 receptor is associated with intact human erythrocyte membranes after a short-time incubation at low pH (1-2 min, pH lower than 5, 37°C). Epifluorescence microscope observations showed that after incubation of red cells with fluorescein isothiocyanate (FITC) labeled anti CD4 monoclonal antibodies (Leu 3a) the erythrocyte membrane and subsequently formed ghost membranes were fluorescent. Immunoelectron microscopy showed 10 nm gold beads associated with CD4 bearing erythrocyte membranes after incubation with anti-CD4 antibodies and then with gold beads coated with immunoglobulin G antibodies. The insertion of CD4 in RBC membranes proved stable, in vitro at 37°C for 24 hrs and the life span of RBC subjected to the acid-insertion did not change as compared to normal RBC in mouse and in man.
CD4$^+$-RBC were shown to attach gp120 and quantitation of the number of CD4 molecules per RBC needed for effective attachment to gp120 was realized. HIV-1 interacts with CD4$^+$-RBC showing in freeze etching EM micrographs the appearance of "foot prints" on the CD4$^+$-RBC membrane, reminiscent of those observed after interaction of influenza virus with RBC. Thus, a long-lived CD4 carrier is obtained with the potential of a scavenger in the circulation of free HIV-1, cilating gp120 antigen and gp120-expressing, HIV-infected T4 cells.

M.C.P.103

TREATMENT OF AIDS ASSOCIATED TUMORS WITH RECOMBINANT DNA GRANULOCYTE-MACROPHAGE COLONY STIMULATING FACTOR (GM-CSF). Tirelli Umberto*, Saracchini S*, Lazzarin A.**, Sorio R.*, Mazzanti P.***, Monfardini S.* * Centro di Riferimento Oncologico, Aviano, Italy; **L. Sacco Hospital, Milan, Italy; ***Essex-Schering, Milan, Italy.

Objective. To evaluate GM-CSF in HIV-related malignant tumors. Methods. Since November 1988 we are evaluating in an open label single patient compassionate exemption case GM-CSF (Schering), in patients with HIV-associated tumors and neutrophil counts < 1000/mm³ after chemotherapy and/or AZT. GM-CSF was administered in doses of 3-5mg/kg/day in a 6 hour iv. infusion for 5 days. Six patients have already been treated, 3 with Kaposi's sarcoma (KS), 2 with Hodgkin's disease and 1 with non-Hodgkin's lymphoma (NHL) with bone marrow toxicity after chemotherapy and/or AZT. Results. In 3 patients, 2 with KS and 1 with NHL, WBC counts increased rapidly since the second day of infusion as for Table:

N° Pts	WBC/mm³day 1	day 2	day 3	day 4	day 5
1	300	700	1 500	4 200	8 000
2	1 300	2 900	2 300	3 500	4 300
3	700	1 800	2 400	4 900	4 000

Mild side effects such as flu-like symptoms, were observed in most patients. There is no clear evidence of worsening of HIV-disease during GM-CSF treatment. Conclusion. Our data indicates that GM-CSF may increase the WBC counts in leukopenic patients receiving chemotherapy and/or AZT for HIV-related malignancies. Supported by a CNR-AIDS grant.

M.C.P.104

IN VITRO INHIBITION OF HIV REPLICATION BY GLUCOSYL PHOSPHOLIPID DERIVATIVES OF NUCLEOSIDE ANALOGS
Schwartz Olivier,Henin Y.,Montagnier L.
Unite d'Oncologie Virale ,Institut Pasteur,Paris,France.

Objective.Glucosyl phospholipid derivatives of nucleosides were synthesized in order to improve their trans membrane passage.They have been compared to AZT and DDC for their ability to inhibit HIV replication in vitro.
Methods. The compounds were synthesized by the Unite de Chimie Organique,Institut Pasteur. Anti HIV effects and cytotoxicity of these derivatives (at concentration ranging from 0,2 μM to 25 μM) were evaluated in CEM-Cl13 cells.Assays were done in 96-well plates,using a method developed in our laboratory.Cells were kept in culture for 22 days.After 7 days and every 3 or 4 days,50 % cytotoxic dose (CD 50) and 50 % antiviral effective dose (ED 50) were evaluated by using the MTT absorbance method.HIV replication was monitored by measurement of reverse transcriptase (RT) activity in cell supernatants.
Results. 11 compounds were shown to inhibit HIV-induced cytopathogenicity until 7 days in culture.Table indicates results obtained with 4 compounds,including AZT and DDC,that inhibited HIV-induced cytopathogenicity for 22 days.Viral production,monitored by RT activitymeasurement,was also inhibited,at least for the higher non toxic concentrations of these compounds.

Days in culture		D7		D11		D19		D22	
		CD50	ED50	CD50	ED50	CD50	ED50	CD50	ED50
Compound	DDC	7	< 0,2	0,4	-	< 0,2	-	<0,2	-
	6651	11	< 0,2	3	< 0.2	3	< 0.2	3	0,8
	6715	> 25	< 0,2	> 25	< 0.2	> 25	0.7	> 25	0.9
	AZT	> 25	< 0,2	23	< 0.2	> 25	< 0.2	23	0.45

Conclusion. 1 glucosyl (compound 6715) phosphodiester derivative of pyrimidine nucleoside showed long term anti HIV activity.Further investigations are in progress.

M.C.P.105

ROLE OF HIV ANTI-SENSE RNA IN HIV REPLICATION
Federico, Maurizio; Carlini, F.; Taddeo, B.M.R.; Orecchia, A.; Saggio, I.; Di Rienzo, A.M.; Verani, P.; Rossi, G.B.
Laboratory of Virology, Istituto Superiore di Sanità, Rome, Italy.

Objective. The analysis of the ability of anti-sense RNA transcribed from a transfected anti-sense HIV DNA to inhibit HIV replication in cell culture. HIV infection of HIV-sensitive cells, previously infected with the anti-sense recombinant retrovirus, may help define the possible role of anti-sense RNA in the inhibition of HIV replication.
Methods. We have molecularly cloned an HIV variant from an Italian AIDS patient and subcloned it in the anti-sense orientation in retroviral vectors under the control of MLV LTRs (pLJ vector) or SV40 (MSV vector) promoters.
Results. Preliminary sequencing indicates nearly 90% of homology between our HIV isolate and the BH10 reference clone, so that a correct intracellular hybridization of anti-sense RNA with the viral RNA of a superinfecting HIV is likely to occur. After transfection of the anti-sense pLJ construct in the retroviral packaging line PA317, we have isolated >40 G418-resistant clones. Co-cultivation with CEM-ss performed shortly after transfection before the isolation of the G418-resistant clones has lead to the isolation of a CEM G418-resistant population.

M.C.P.106

ORGANIC GOLD COMPOUNDS ARE EFFECTIVE AGAINST HIV 1 REVERSE TRANSCRIPTASE.
Blough, Herbert*¶; Ricchetti, M.*; Montagnier, L.* and Buc, H.*
*Institut Pasteur, Paris, France, ¶University of Pennsylvania, Philadelphia, PA, USA

Objective. To show that simple glucose or mannose analogues, which are potent glycosylation inhibitors, could be modified by the addition of gold so that they became powerful inhibitors of reverse transcriptases *in vitro*.
Methods. Preliminary screening methods have demonstrated that certain hexose analogues were potent glycosylation inhibitors of gp120 *in vitro* (CEM cells). These compounds were not effective against HIV-RT. 1-Aurothioglucose (AuT) and various Au-containing aliphatics were prepared. These were effective against HIV1-RT in cell lysates. To determine the molecular mode of action, we examined the effect of these inhibitors at different steps of the DNA polymerization process, directed by reverse transcriptases (enzyme-template complex formation, chain initiation and chain elongation). Product analysis was performed using a chain elongation assay with [^{32}P] primer, both with non-specific and HIV templates.
Results. AuT was the most effective against both HIV and AMV-RT with an apparent K_i of 3 μM for HIV-RT and 20 μM for AMV-RT. AuT acted on the free RT and on the RT-template complex. The active elongation complex was also inhibited by AuT. An aliphatic compound with four carbons and the same prosthetic group was fifty to one hundred times less active than AuT. Analogues lacking Au were not active against either RT.
Conclusion. 1-Aurothioglucose is an highly effective compound which inhibits the initiation and elongation of DNA chains by HIV and AMV-RTs. Unlike nucleoside analogues, this compound does not require cellular phosphorylation to be active and may be useful in the treatment of AIDS and related diseases.

M.C.P.107

ACID-STABLE 2',3'-DIDEOXYPURINE NUCLEOSIDES WITH THE POTENTIAL FOR IMPROVED ANTI-AIDS ACTIVITY IN THE CENTRAL NERVOUS SYSTEM
Driscoll, John S.;Marquez, V. E.;Barchi, J. J.;Ford, H.; Cooney, D. A.;Mitsuya, H.;et al.
National Cancer Institute, NIH, Bethesda, MD., U.S.A.

Objective. To prepare orally active, acid-stable dideoxypurine nucleosides with partition coefficients in the range log P = -0.5 to +2.5 in order to maximize blood-brain-barrier penetration.
Methods. All of the dideoxypurine nucleosides prepared contain a 2'-fluoro atom in order to stabilize their glycosylic bonds to the acidic conditions which orally administered drugs experience. Compounds are synthesized and evaluated for their ability to protect ATH8 cells from the cytopathogenic effects of HIV. Partition coefficients are calculated. Metabolic studies are performed using both isolated enzyme and cellular systems.
Results. 2',3'-Dideoxy-2'-fluoroarabinofuranosyl purine nucleosides have been designed to evaluate the hypothesis that the partition coefficient of a compound can be correlated with its CSF to plasma ratio and that this information can be used to determine optimum compounds for CNS penetration. 2'-F-dd-ara-A is just as active and potent as ddA in protecting ATH8 cells from HIV and is slightly more lipophilic (log P -0.1 and -0.2 respectively). The corresponding deaminated product, 2'-F-dd-ara-I, is equally active but is less lipophilic (log P ca. -1.0). In order to circumvent deamination and the production of hydrophylic products, the simplest member of this series, 2'-F-dd-nebularine (log P ca. +1.0), was prepared but was found to be inactive. Other compounds in this series have been synthesized and are being evaluated.

M.C.P.108

A NOVEL COMPOUND THAT INHIBITS REVERSE TRANSCRIPTASE
Ohnota,Hideki**;Morikawa,S.*;Momose,D.**;Ushijima,H.*; Kurashina,Y.**;Kitamura,T.*
*AIDS Research Center,National Institute of Health,Japan, **Creative Products Research Laboratories,Kissei Pharmaceutical Co. Ltd.,Matsumoto,Japan.

Objective. We tried to develope new drugs for treatment of AIDS.
Methods and Results. We tested about 500 compounds for anti-HIV activity and found an effective compound. Screening was done using T cell line(MT-2) and HIV-1. This novel compound is a derivative of 4H-quinolizine and its code is KAV-397. KAV-397 suppressed proliferation of HIV-1 in T lymphocyte cell line. When T cells(MT-4) were infected with HIV-1 and co-cultured with KAV-397(4-12 μg/ml)they proliferated without cytopathic effect for 7 days at the same growth rate of uninfected cells. KAV-397 suppressed reverse transcriptase activity of HIV-1. Inhibition of the reverse transcriptase was observed from the concentration of 1 μg/ml in a dose dependent manner. Analyses of mode of action of KAV-397 revealed noncompetitive inhibition of the reverse transcriptase. Further, we tested efficacy of KAV-397 in vivo using mouse retrovirus system. C57/B10 mice were infected with MuLV(LP-BM5) and 5 weeks after infection spleen cells were tested for response to mitogens(PHA and LPS). AZT in drinking water(0.3 mg/ml) was administered to positive control group. KAV-397 was administered intraperitoneously(30 and 100 mg/Kg/day). AZT treatment was effective but KAV-397 had little effect on the immunosuppression induced with LP-BM5. These results indicated limitting efficacy of KAV-397. We are now studying the effect of this compound on other retroviruses.
Conclusion. This compound has possibility of being one of new drugs for treatment of AIDS.

M.C.P.109 CHRONICALLY INFECTED MONOCYTE-MACROPHAGES (Mφ) ARE MARKEDLY LESS SENSITIVE TO ZIDOVUDINE (AZT), FOSCARNET (FOS) AND ALPHA INTERFERON (IFN) WHEN COMPARED TO ACUTELY INFECTED Mφ.

Crowe, Suzanne, McGrath, M.S. Elbeik, T. Kirihara, J. McManus, N. Mills, J. San Francisco General Hospital/University of California, San Francisco, California, USA.

Objective: Mφ are thought to provide a major reservoir of HIV in vivo. We therefore studied the efficacy of representative antiretroviral drugs in both acutely and chronically HIV-infected mφ.
Methods: Mφ isolated from peripheral blood of HIV seronegative donors were infected in vitro with HIV-DV (multiplicity of one). Antiretroviral was added either at time of infection (acute) or 10-15 days following infection when 25% of mφ contained HIV p24 by cytofluorographic analysis (chronic). Control cultures contained no drug. Inhibition of HIV replication was assessed by measurement of HIV antigen (Abbott ELISA) in culture supernatant and cell lysates, and HIV RNA analysis by slot-blot.
Results: AZT, FOS and IFN markedly inhibited HIV replication in acutely infected mφ; (>90% inhibition with ⩾0.01 ug/ml AZT and ⩾100 ug/ml FOS, 88-99% with 1000 U/ml IFN). Comparable inhibition was seen in synthesis of both extracellular and intracellular HIV antigen, with accompanying suppression of HIV RNA. Chronically infected mφ were markedly less sensitive to these compounds even at high concentration; (<50% inhibition with AZT 50 ug/ml, FOS 100 ug/ml, IFN 1000 U/ml). Slot-blot analysis showed no diminution of RNA in chronically infected mφ.
Conclusion: Acutely infected mφ are susceptible to antiretrovirals; chronically infected mφ (which probably constitute the main in vivo reservoir for HIV) are several orders of magnitude more resistant.

M.C.P.110 COMPUTERIZED QUANTIFICATION OF SYNERGISM/ANTAGONISM OF ANTI-HIV AGENTS

Chou, Ting-Chao,* and Chou, Joseph.**
* Mem. Sloan-Kettering Cancer Ctr., Cornell Univ. Grad. School of Med. Sci., NY, NY 10021, and** Duster I-43, Harvard Univ., Cambridge, MA 02138. USA.

Objective. To introduce and illustrate computerized simulation of synergism/additivism/antagonism of two or more anti-HIV-agents using the median-effect principle of Chou and Talalay (Adv.Enz.Regul.22:27-55, 1984).
Method. Computer software "Dose-Effect Analysis with Microcomputers" by J. Chou and T.-C. Chou, Elsevier-Biosoft, Cambridge UK, 1986, has been upgraded and used for studying anti-HIV drug interaction in terms of synergism or antagonism for IBM PC, AT, or XT. In addition to automated construction of isobolograms, F_a-CI plot and F_a-CI table for two drugs, the new feature includes, F_a-log(CI) plot, dose-reduction index (DRI), selectivity index (SI), and three-drug combinations.
Results. Using small number of measurements with reverse transcriptase, P_{24} antigen, virus yield and IFA, the following questions about synergism can be studied: 1) the potency of drug(s); 2) the shape of dose-effect curve (m); 3) the variability of data (r); 4) how much synergism? ; 5) the doses at which synergism occurs (D); 6) the effect levels at which synergism occurs (f_a); 7) the optimal dose combination ratio for maximal synergy (ODCR); 8) schedule dependency; and 9) selectivity index (SI) for anti-HIV/cytotoxicity ratio.
Conclusion. Usefulness of MEP and the software have been demonstrated [e.g. Antimicrob. Agent Chemother. 31:168, 1987 (AZT+IFN); 33:53, 1989 (AZT+CAS); Science 235:1376, 1987 (AZT+RBV); and J.Inf.Dis. 158:378, 1988 (ddC+IFN)].

M.C.P.111 POSSIBLE PROTECTIVE EFFECT OF DEHYDROEPIANDROSTERONE (DHEA) AND/OR DHEA-SULFATE (DHEA-S) IN HIV INFECTION

Jacobson, Mark A, Lekas P, McGrath MS. SF General Hospital and UCSF, San Francisco, CA. USA

Objective. Since DHEA has been reported to have immunomodulatory/antiviral activity, we studied 1) the relationship between endogenous DHEA-S levels (DHEA is rapidly converted *in vivo* to DHEA-S) and HIV infection and 2) the *in vitro* effect of DHEA on HIV-infected macrophages.
Methods. DHEA-S was measured by RIA and HIV antibody assayed by two ELISA techniques (positive [+] results confirmed by Western blot) in coded serum samples obtained from 5 groups of men who were age-matched within 3 years. *In vitro*, human macrophages exposed to HIV (one $TCID_{50}$ unit/cell) for 1 hour were cultured with various DHEA dilutions. Supernatants were assayed for p24 antigen at 9 days and % inhibition of p24 compared to untreated controls.
Results. Group I (24 HIV- homosexuals who sought medical advice regarding a possible AIDS diagnosis) had a mean (±SD) serum DHEA-S level of 5.97 (±3.01) ug/ml, compared with Group II's (24 healthy HIV+ homosexuals) mean level of 2.20 (±1.33) ug/ml (p<.0001), Group III's (24 HIV+ ARC patients) mean of 2.12 (±1.35) ug/ml (p<.0001), Group IV's (24 HIV+ AIDS patients) mean of 2.51 (±1.74) ug/ml (p<.0001), and Group V's (48 HIV- healthy blood donors) mean of 3.19 (±1.58) ug/ml (p=.0002). *In vitro*, 50% inhibition of macrophage HIV p24 expression occurred at DHEA concentrations of 3-30 ug/ml.
Conclusion. At-risk HIV seronegative homosexual men had a significantly higher serum DHEA-S level than age-matched HIV+ men or healthy HIV- blood donors. DHEA also modestly inhibited HIV replication *in vitro* in human macrophages. DHEA/DHEA-S may have a protective effect in HIV infection.

M.C.P.112 SOMATOSTATIN ANALOG INHIBITS HIV-1 REPLICATION IN A HUMAN MONOCYTIC CELL LINE.

Marcure, Louis*; Phaneuf, D.**; Morisset, R.**; and Wainberg, M.A.*
*Jewish General Hospital, Montreal, Quebec, Canada, **Hôtel-Dieu de Montréal, Montreal, Quebec, Canada.

Objective: Sandostatin is a long-acting somatostatin analog used to treat the diarrhea of AIDS patients. Because this diarrhea could directly involve the HIV-1 retrovirus, we have investigated the anti-viral potential of Sandostatin in monocytes.
Methods: Five different concentrations of Sandostatin (Sandoz; SMS 201-995), ranging from 10^{-6} M to 10^{-14} M were tested on the U-937 monocytic cell line. In one protocol, cells received drug for 24 hours prior to infection with the HTLV-III_B strain of HIV-1. Alternatively, cells were treated with drug at the time of infection and thereafter pulsed daily or every three days. Viral replication was assessed by each of indirect immunofluorescence, reverse transcriptase assay and antigen capture (p24) assay.
Results: Somatostatin inhibited HIV-1 replication by up to 85% in acutely-infected U-937 cells. This inhibition was not dose-dependent at the range of drug doses used. Similar levels of inhibition were obtained regardless which treatment protocol was employed.
Conclusion: The long-acting somatostatin analog, Sandostatin, is effective against HIV-1 replication in a human monocytic cell line. These results reinforce the multiple potential of this analog as a therapeutic drug in AIDS patients.

M.C.P.113 ANALYSIS OF THE EFFECT OF ACETAMINOPHEN ON ZIDOVUDINE PHARMACOKINETICS IN HIV INFECTED PATIENTS

*Steffe Erika, *Inciardi J, *King J, *Flynn N, *Goldstein E, and *Tanjes T.
*University of California Davis, Medical Center, Sacramento, CA, USA

Objective. To determine if acetaminophen (A) affects the pharmacokinetics of zidovudine (Z) in HIV infected patients.
Methods. HIV infected patients being treated with zidovudine were entered into a 2 phase trial of oral Z alone followed by concomitant oral Z/A administration. Patients abstained from food for 12 hours prior to the morning 200mg Z dose. In both phases Z levels were obtained at trough, .25, .5, .75, 1.0, 1.25, 1.5, 2.0, 2.5, 3 and 4 hours after the dose. In the Z/A phase, A (650mg) was initiated 48 hrs prior to [Z] analysis given every 6 hrs and 2.5 and 0.5 hrs prior to Z administration.
Results.

		Patient A	Patient B	Reported
Peak Time (hr)	Z	0.5	0.3	
	Z/A	0.5	0.3	0.5 - 1.5
Peak (mcg/ml)	Z	1.67	1.31	
	Z/A	1.14	0.91	0.05 - 1.46
Half Life (hrs)	Z	1.2	0.8	
	Z/A	1.0	0.5	0.78 - 1.93
AUC (mM/L x hr^{-1})	Z	8.47	2.83	
	Z/A	6.22	1.39	

Conclusions. Observations from preliminary data from two patients have not demonstrated an acetaminophen interaction with zidovudine's pharmacokinetic processes of absorption, distribution or elimination.

M.C.P.114 COMPARATIVE EVALUATION OF THREE THYMIDINE ANALOGS (D4T, FDDT AND AZT) ACTIVE AGAINST HIV

Roman Z. Sterzycki, et al.
Bristol-Myers Company, Pharmaceutical Research and Development Division, Infectious Diseases, Wallingford, Connecticut, U.S.A.

Objective: To evaluate the pyrimidine nucleoside analogs d4T and FddT as potential anti-AIDS drugs.
Methods: The anti-HIV effect of the title nucleosides was studied in HIV infected CEM cell line. The corresponding 5′-triphosphates were prepared and Ki′s with HIV RT established both with RNA and DNA oligonucleotide templates. In vitro cell toxicity of d4T, FddT and AZT was compared in CEM cells as well as in the human bone marrow progenitor cells (granulocyte-monocyte colony forming units and erythrocyte burst forming units). In vivo toxicity of d4T, FddT and AZT was evaluated in a 30 day mouse toxicity study at 100 - 1000mg/kg/day. Histopatological and hematological changes in the mice were examined at the end of the study.
Results: 1-(2,3-Dideoxy-β-D-glycero-pent-2-enofuranosyl)thymine (d4T) and 1-(2,3-dideoxy-3-fluoro-β-D--ribofuranosyl)thymine (FddT) were found to be potent in vitro inhibitors of the HIV multiplication. In vitro and in vivo toxicology studies point to profound toxic effects of FddT at most evaluated doses.

TABLE

Compound	ID_{50}(µM)	$TCID_{50}$(µM)	Ki(µM)	$GM\text{-}CFU_{50}$(µM)	E-BFU(µM)
d4T	.15-.33	90	.03-1	100	10
FddT	.007-.1	51-73	.26	10	1
AZT	.16-.45	29-54	.004-.02	1	6.7

Conclusions : D4T and FddT are potent inhibitors of HIV in vitro with d4T exhibiting much lower toxicity in vitro and in vivo. These data form a basis for further evaluation of d4T as a drug against HIV infection.

M.C.P.115 ANTI-HIV-1 ACTIVITIES OF ANTHRAQUINONE DERIVATIVES IN VITRO

C. K. Chu*; R. F. Schinazi†; M. Nasr#
*The University of Georgia College of Pharmacy, Athens, Georgia 30602, †Emory University School of Medicine/VA Medical Center, Atlanta, GA 30033, #National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD 20892, U.S.A.

Objective. As a part of our efforts to discover novel anti-HIV agents, a series of anthraquinone derivatives have been screened against HIV-1.
Methods. Peripheral blood mononuclear cells were infected with HIV-1 and cultured in the presence and absence of various concentrations of compounds. Six days later the reverse transcriptase activity was determined as a measure of antiviral activity.
Results. In order to determine the structure-activity relationships, various anthraquinones substituted with OH, NH2, SO3Na, halogens, aromatic, amines, etc., were evaluated against HIV-1. Among these, poly-phenolic and/or poly-sulfate substituted anthraquinones were found to be most potent, such as 1,2,5,8-tetrahydroxyanthraquinone(EC50=3.29µM), 1,2,4-trihydroxyanthraquinone(EC50=3.44 µM), 3,4-dihydroxy-9,10-dioxo-2-anthracenesulfonic acid (EC50=3.48 µM). Amino or halogen substituted anthraquinones exhibit low activity. None of the active compounds were toxic at 100 µM. Hypericin, an anthraquinone dimer exhibited a potent anti-HIV-1 activity (EC50=0.44 µM) in this screening system.
Conclusion. A new class of anti-HIV agents with modest activity has been identified. Further study of structure-activity relationships and the mechanism of action are warranted. (Supported by USPHS Grant AI 26055, AI 25899 and the Veterans Administration)

M.C.P.116 AZIDOTHYMIDINE(AZT)-ALPHA-INTERFERON(IFN) COMBINATION THERAPY REDUCES P24 ANTIGENEMIA.

Edlin, Brian R.; Whaling, S.M.; Weinstein, R.A.; Bitran, J.D. Divisions of Infectious Diseases and Hematology-Oncology, Michael Reese Hospital, Chicago, IL. U.S.A.

We report an ongoing phase II dose-escalating/de-escalating trial of IFN in combination with AZT in patients with p24 antigenemia (>45 pg/ml) and AIDS, ARC, or a CD4 count <250/mm^3. Patients with opportunistic infections (OIs), lymphoma, or progressive Kaposi's sarcoma are excluded. All patients must be p24 Ag(+) after at least 6-8 weeks of AZT monotherapy to be eligible. Patients are followed with monthly physicals, CD4 counts, and plasma p24 Ag and B$_2$-microglobulin levels. So far 9 patients have been followed for 7 to 32 weeks of therapy with 600-1200 mg/d of AZT and 1.25-7.5x10^6 u/m^2 of IFN s.c. 3x/wk. A mean reduction in plasma p24 Ag of 45% has been seen in 8 of 9 patients, at a median of 7 weeks. In the 4 followed more than 8 weeks on IFN, a mean reduction in p24 Ag of 58% occurred at a median of 17 weeks. Higher initial CD4 counts predicted greater % reductions in p24 Ag. CD4 counts fell and B$_2$-microglobulin levels rose on therapy. Side effects required IFN dose modification in 6 of 9 patients. In 40 patient-months, no severe OIs occurred. In all 4 patients followed for more than 8 weeks, an initial decline in p24 Ag at 8-15 weeks was followed by a rise toward pre-treatment values at 19-27 weeks. This rise correlated with a fall in %CD4 to below 10%.

We conclude that AZT-IFN therapy is associated with an initial reduction in p24 Ag, a very low incidence of OIs, and a moderate frequency of side effects requiring dose modification. Correlation of a late rise in p24 Ag with a fall in CD4% suggests that early antiviral effects of IFN may be overcome by later immunosuppressive effects.

M.C.P.117 CASTANOSPERMINE ANALOGS AS POTENT INHIBITORS OF HUMAN IMMUNODEFICIENCY VIRUS (HIV)

Sunkara, Prasad*; Taylor, D.**; Kang, M.*, Liu, P.*, Bowlin, T.*, Tyms, A.** and Sjoerdsma, A.*
*Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, OH 45215 USA and **MRC Collaborative Center, Mill Hill, London NW7 1AD, UK.

The objective of the present investigation was to develop potent inhibitors of glycosidases as potential anti-HIV agents. Several analogs of the known inhibitor, castanospermine (CAST), were synthesized and evaluated for their inhibitory effect on glycosidases and for antiviral activity against Moloney murine leukemia virus (MOLV) in the XC plaque assay. The IC$_{50}$ values of these inhibitors against the enzyme and MOLV ranged from 0.8 - 50 µg/ml and 0.05->10 µg/ml, respectively, compared to 10 and 1.2 µg/ml for CAST. The most effective analog was 6-O-butyryl CAST with an IC$_{50}$ of 0.05 µg/ml against MOLV. A good correlation between inhibition of glycosidase and MOLV replication was observed. The active analogs were further evaluated against HIV-induced syncytial formation in HeLa T^{+} cells and against productive infection in JM cells infected with HIV 1 (GB8 strain). The analogs showed IC$_{50}$'s between 0.3 - 27 µg/ml in the HeLa T^{+} assay, compared to CAST at 11 µg/ml. These compounds also showed good activity (IC$_{50}$ = 0.15 - 6.7 µg/ml) in JM cells. In both of these HIV assays, the 6-O-butyryl analog was the most effective, (IC$_{50}$ = 0.15 µg/ml) compared to CAST (10 µg/ml). These data and cytotoxicity studies indicated a therapeutic index of >2000 for the 6-O-butyryl CAST compared to 500 for CAST. These observations were further confirmed by investigation of the 6-O-butyrate against Friend leukemia virus infection in mice. CAST and the 6-O-butyryl analog, when administered at a dose range of 50-200 mg/kg/day i.p for 14 days, reduced the splenomegaly by 0-15% and 60-81%, respectively. These observations demonstrate the potential of the novel glycosidase inhibitors as chemotherapeutic agents in AIDS.

M.C.P.118 ANTI-HIV REVERSE TRANSCRIPTASE AND ANTI-HIV ACTIVITIES OF PC6

H. Takayama, Patrick K. Lai, Y.T. Wu and M. Nonoyama
Department of Virology, Showa University Research Institute, St. Petersburg, FL. 33716, USA.

Previously we have shown that PC6, a partially purified extract from cones of pinus parvifloria Sieb et Zucc, inhibited HIV-1 replication in CEM, H-9 and U937 cells. Here we show that PC6 has anti-HIV-1 reverse transcriptase (RT), anti-AMV-RT activities. Addition of PC6 to the reaction mixture of the RT assay inhibited HIV-1-RT and AMV-RT activities. Gel-retardation assay showed that PC6 did not bind to DNA or the template. Competition assay revealed that PC6 directly impact on HIV and AMV RTs. The anti-RT active component(s) in PC6 could be removed by an affinity column of CEM cells. Sequential Tris-glycine (0.1M, pH 3.0 and 0.1M, pH 8.0) elution did not recover the anti-RT component(s), but the eluate contained anti-HIV activity. The replication of HIV in CEM cells was inhibited after exposure of the infected cells to the eluate (3µg/ml). Thus, PC6 contains 2 active components: an anti-RT component and an anti-HIV component that had no impact on HIV-RT. Further purification of these active components in PC6 is in progress.

M.C.P.119 EFFECT OF CHLOROQUINE ON HIV1 INFECTION OF MONOCYTES

Desportes, Isabelle*, Fouchard, M.*; Pyne, Ch.K. **; Réveil, B.*

* Physiologie Cellulaire, ** Génétique du Développement
Université P. et M. Curie, Paris France

Objective : Ultrastructural analysis of HIV infection of monocytes.
Methods : Monocytes were isolated from normal donor blood samples by Hypaque-Ficoll sedimentation and sepracell, then incubated with virus in presence or in absence of chloroquine (120 micromoles for a period of 6 hours or 50 micromoles overnight). Cytological study was performed with electron microscopical techniques.
Results : The treatment of HIV infected monocytes by chloroquine resulted in the formation of intracellular vacuoles containing virions in various stages of degradation similar to those observed in SFV infected cells treated with lysosomotropic agents (1) and in HSV infected cells expressing a glycoprotein that interferes with the fusion reaction of virion envelope with the cell membrane (2). By contrast such intravacuolar accumulations of virions were not observed in HIV infected monocytes not treated by the drug.
Conclusion : These preliminary data suggest that chloroquine may affect the penetration of HIV into the cytoplasm of monocytes.

M.C.P.120 CELLULAR PHARMACOLOGY OF ANTI-HIV AGENTS AZIDOTHYMIDINE (AZT) AND 2',3'-DIDEHYDROTHYMIDINE (D4T) IN HUMAN T CELLS

Fridland, Arnold; Connelly, M. and Ashmun, R.
St. Jude Children's Research Hospital, Memphis, Tennessee 38101 U.S.A.

Objective. AZT is the first effective agent in the treatment of AIDS. However, bone marrow toxicity and anemia is a severe adverse effect of AZT therapy. This toxicity has been linked to depletion of deoxynucleoside triphosphate (dNTP) for DNA synthesis. This study compared the metabolism and inhibitory effects of AZT and that of its analog D4T in human T cells CCRF-CEM.
Results. The concentration of the drugs required to inhibit cell growth by 50% (EC$_{50}$) was significantly lower when the cells were exposed to AZT and D4T for 24 h (EC$_{50}$=40 and 25 µM, respectively) than 48 h (EC$_{50}$=125 and 55 µM). Inhibition of DNA synthesis induced by either drug did not correlate with dNTP depletion in cells. The 5'-phosphate of AZT (AZTMP) was the major metabolite (>99%) reaching 300-fold greater cellular concentration than that observed with D4T at equimolar concentration of the two drugs. Cells incubated with 25 µM AZT accumulated >1 mM AZTMP after 4 h while both AZTDP and AZTTP plateaud at about 5 µM. After this period there was a rapid decrease in AZTMP accumulation to one third its initial level by 24 h, while both AZTDP and AZTTP appeared stable. D4T is a poorer substrate than AZT for the cellular kinase but produced considerably higher level of the analog triphosphate in CEM cells at equimolar concentration of the two drugs.
Conclusion. These results do not support the notion that depletion of dNTPs is a primary cause for the toxicity of AZT or D4T and suggest that the analog triphosphate levels are the important determinants of cellular sensitivity to these drugs. (Supported by NIH grant CA43296, CA21765 and by the American Lebanese Syrian Associated Charities.)

M.C.P.121 ANTI-HIV ACTIVITIES OF A NOVEL NUCLEOSIDE OXETANOCIN AND ITS DERIVATIVES

Seki Jun-ichi*,**; Takeuchi, T.***; Shimada, N.**; Takahashi, K.**; Takita, T.** and Hoshino H.*.
*Gunma University, Maebashi, Japan, **Nippon Kayaku, Co., Ltd., Tokyo, Japan, ***Institute of Microbial Chemistry, Tokyo, Japan.

Objective. Oxetanocin (OXT-A) is a nucleoside containing a 4-membered sugar and adenine. We modified OXT-A at the sugar or base moiety and examined effects of OXT-A and its derivatives on life cycle of HIV. Methods. 1)Oxetanocins: OXT-A is produced by B. Megatherium. Its derivatives were produced chemically or enzymatically. 2)Infectivity assay by IFA: MT-4 cells were infected with HTLV-III$_B$. Four days later, the expression of HIV antigen in MT-4 cells was examined by IFA. 3)Syncytium assay: Molt-4 cells and Molt-4/HTLV-III$_B$ cells were cocultured for 22 hours and the number of syncytia formed was counted. 4)Southern blot assay: MT-4 cells were infected with HTLV-III$_B$ at m.o.i. 15-30. After incubation for several hours, DNA was extracted from the cells. 5)HIV RT assay: HIV RT was assayed using poly(dT)-oligo(dA) or poly(rA)-oligo(dT) as a template-primer. Results. Oxetanocins inhibited the expression of HIV antigen in MT-4 cells after de novo infection and the synthesis of viral DNA at non-cytotoxic concentration, but not syncytium formation. Triphosphate form of OXT-A inhibited HIV RT activity. Some of derivatives changed at the sugar moiety had much stronger anti-HIV activities than OXT-A. Conclusion. Oxetanocins exerted anti-HIV activities by inhibiting the synthesis of proviral DNA. This inhibition was suggested to be due to formation of oxetanocin triphosphates in the cells.

M.C.P.122 COMPUTER ASSISTED STRUCTURE-ACTIVITY CORRELATIONS OF POTENTIAL ANTI-HIV DRUGS

M. Nasr, Charles Litterst, P.Johnston, J.McGowan, AIDS Program, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, USA, 20892

Objective: to avoid duplication in synthesis of novel compounds, to indicate more productive research directions, and to disseminate that information in an international forum. Methods: data retrieval from our computerized data base which contains information on published active and inactive anti-HIV compounds was used to analyze structure-activity relationships among more than 300 pyrimidine and purine nucleosides and their carbocyclic and acyclic analogs. Results: the sugar moiety has been the subject of modifications including degree of saturation, configuration, and acyclic or carbocyclic replacement, while modifications have been made to substituents on the pyrimidine or purine ring systems. Active pyrimidine nucleosides have a preference for a 3'-azido or fluoro substituent in the exo configuration, in the presence of a 5-methyl substitution. A 2',3'-double bond, while enhancing the anti-HIV activity of certain nucleosides, did not enhance activity among other related nucleosides. A 3'-fluorine enhances activity, while a 3'-Cl, Br or I gave inactive compounds. The only active acyclic nucleosides reported so far have a phosphonate group in the aliphatic side chain. Only a few aza and deaza-2',3'-dideoxynucleosides have been reported and all have been inactive. A comparison of the in vitro activity of a series of nucleosides in different cell lines (MT-4, ATH8,PBM, MuLV) will be presented. Conclusion: structure activity correlations can be used to effectively avoid duplication of chemical syntheses, and to indicate more productive directions for AIDS drug development research.

M.C.P.123 DISCOVERY AND DEVELOPMENT OF THERAPIES FOR AIDS AND ITS SEQUELA

Margaret I. Johnston, C. Litterst, and J. McGowan
Developmental Therapeutics Branch, AIDS Program, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD 20892, USA

Objective. Through the AIDS Program, the NIH has established programs to assist international efforts to identify and develop novel therapies for HIV infection and associated opportunistic infections (OIs). Methods. The Developmental Therapeutics Branch, AIDS Program, NIAID was established in 1987. Major thrusts include the National Cooperative Drug Discovery Group (NCDDG) Program for the Treatment of AIDS (NCDDG-AIDS) and the new NCDDG Program for the Treatment of OIs (NCDDG-OI). These collaborative agreements foster interactions between academic, industrial and government scientists and pool diverse talents and resources to discover new potential therapies. Initiatives to complement these efforts include an animal models program for evaluating potential therapies and immunomodulators and the NIH AIDS Research and Reference Reagent Program. Results. The NCDDG program has been recognised by academia and industry as an innovative and comprehensive model by which the government may assist basic and applied research efforts to discover new potential therapies. This program has been highly successful, already having identified 3 new compounds that will enter clinical trial and that will by discussed. Conclusions. These broad-based efforts permit AIDS Program staff to assess current approaches and identify areas that require additional effort. A better understanding of these resources, programs and future initiatives on the part of investigators worldwide will facilitate expansion of this international effort and stimulate the discovery and development of better therapies for AIDS and the OIs associated with AIDS.

M.C.P.124 INHIBITORY EFFECTS OF UNSATURATED PHOSPHOLIPIDS ON HIV PRODUCTION IN VITRO

Lewis, Dorothy[1]; Baran, A.J.[2]; Knight, V.[1]; and Jett, M.[3]
[1]Dept. Microbiol. & Immunol., Baylor College of Medicine, Houston, TX 77030, [2]Houston Biotechnology Inc., The Woodlands, TX 77381, and [3]Div. Path., Walter Reed Army Institute of Research, Washington, DC 20307 USA.

Plant phosphatidylinositol (PPI) containing two or more sites of unsaturation in the sn-2 fatty acid is cytotoxic to many tumor cell lines in culture (e.g. multidrug resistant tumor cells, IC_{50}=1-2μM) which may be due to interference with certain signal transduction pathways.[3] Because the production of human immunodeficiency virus (HIV) requires activation of cells, we examined several phospholipid formulations for their ability to inhibit HIV production from HIV-infected T cell tumors in vitro. PPI, phosphatidylcholine, and phosphatidylethanolamine with the same unsaturation pattern exhibited similar anti-HIV activity as assessed by the production of p24 antigen (IC_{50}=16-20mM). Phospholipids containing fully saturated fatty acids did not have anti-HIV effects. After 4 days in culture, the active compounds also caused reduction in ^{3}H-thymidine incorporation at concentrations above 25μM due to a reduction in numbers but not viability of cells. The reduction in ^{3}H-thymidine incorporation in the infected cells was at least 2-fold greater than the effect on uninfected cells. The compounds failed to inhibit syncytia formation between infected and uninfected CD4^{+} cells suggesting that the mode of action was not to inhibit HIV binding to susceptible cells. The mechanisms responsible for the reduction in HIV production are not clear, but it may be that HIV severely alters certain metabolic activation pathways in infected cells and continued production of HIV is contingent upon the proper functioning of these signal transduction pathways.

M.C.P.125 FURTHER STUDIES ON THE POTENT ANTIVIRAL SYNERGISM OF CARBOVIR AND AZT AGAINST HUMAN IMMUNODEFICIENCY VIRUS (HIV) IN VITRO.

Shannon, William M.*; Lavelle, George C.*; Qualls, K. Jeanine*; White, E. Lucile*; Johnson, Joan M.*; and Vince, Robert**.
*Southern Research Institute, Birmingham, AL, U.S.A., **University of Minnesota, Minneapolis, MN, U.S.A.

The marked antiviral synergism of the carbocyclic analog of 2',3'-dideoxy-2',3'-didehydroguanosine (Carbovir) and 3'-azido-3'deoxythymidine (AZT; Retrovir) combination against human immunodeficiency virus (HIV) replication in MT-2 cells was reported earlier (Shannon et al., IV Intl. Conf. on AIDS, Stockholm, Sweden, 1988). We have further characterized and optimized the effects of these potent anti-HIV drugs when used in combination. Additional experiments have confirmed the potent synergistic activity of Carbovir + AZT combinations, have established the optimal ratio of the two drugs for maximum effectiveness, and have compared the synergistic efficacy of the two-drug combination in different cell lines. Using the Chou and Talalay equations for the analysis of multiple drug effects, it was established that the optimal combination ratio is 1:0.032 (Carbovir:AZT). The median-effect plots indicate that the two drugs are mutually nonexclusive. FA-CI plots and conservative isobolograms indicate synergism at all levels. The antiviral selectivity of the optimal Carbovir + AZT combination was examined quantitatively and it was found that the anti-HIV effect is achieved with less-than-additive cytotoxicity. Data will be presented on the synergistic inhibition of HIV production in H9 cells by Carbovir + AZT combinations using reverse transcriptase levels and p24 gag protein expression as the endpoints.

M.C.P.126 QUANTITATIVE ANALYSIS OF HIV-1 EXPRESSION USING MAGNETIC PARTICLE RNA-RNA HYBRIDIZATION: APPLICATION TO ANTI-HIV DRUG SCREENING.

Scott Decker[1], K.A. Logan[1], J.M. Lawrie[1], M.G. Pellegrino[2], G. Li[2] and D.J. Volsky[2]. [1]GENE-TRAK Systems, 31 NY Ave., Framingham, MA, USA 01701 and [2]St. Luke's Roosevelt Hospital, Columbia University College of Physicians & Surgeons, NY, NY, USA 10019.

Objective. To demonstrate the utility of an unique hybridization assay for the quantitative detection of RNA transcripts of the human immunodeficiency virus-1 (HIV-1) *pol* gene. Methods. HIV-1 infected cells *in vitro* were quickly prepared by solubilization in the chaotropic salt, guanidine thiocyanate (GuSCN). GuSCN lysates were mixed with specific HIV-1 probes: poly(dA) oligomer capture probes and a [^{125}I]CMP RNA detector probe. Viral nucleic acid target-probe complexes were bound to, or captured by oligo(dT) magnetic particles and repeatedly cycled by washing, eluting and recapturing, effectively reducing nonspecific background levels. Results. CR10, or H9 cells, infected with the HIV-1N1A, or HTLV-IIIb isolate, respectively, were treated with azidothymidine (AZT) or dideoxycytidine (DDC) and HIV RNA levels were measured, as well as HIV antigen by immunofluorescence (IF). The results for the IIIb isolate are shown:

days postinfection		μmolar AZT				μmolar DDC				no drug
		100	10	1.0	0.01	1000	100	10	0.01	
Day 2	RNA (pg/2x10^5 cells)	6	10	11	15	0	2	2	22	88
	% cells IF positive	0	0	0	0	0	0	0	0	4
Day 4	RNA (pg/2x10^5 cells)	4	7	12	31	0	0	1	37	440
	% cells IF positive	0	0	0	3	0	0	0	1	54

Conclusions. The data demonstrate the sensitivity of an unique nucleic acid hybridization assay for both the rapid and quantitative determination of intracellular levels of HIV-1 RNA, and its use in anti-viral drug screening.

M.C.P.127 PHARMACOKINETICS OF RECOMBINANT SOLUBLE CD4 (sT4) IN CYNOMOLGUS MONKEYS FOLLOWING INTRAVENOUS ADMINISTRATION

Fong, K.L.L.; Boyle, K.E.; and Crysler, Carl. Department of Drug Metabolism, Smith Kline & French Laboratories, King of Prussia, PA 19406 U.S.A.

Objective. To characterize the pharmacokinetics of recombinant soluble CD4 (sT4) protein in cynomolgus monkey to assist in the design of initial sT4 clinical trials.
Methods. SK&F sT4 and ^{125}I-labeled SK&F sT4 were administered as a single 300 ug/kg bolus intravenous dose in 4 conscious male cynomolgus monkeys. Blood samples were collected up to 6 hours post-dosing and analyzed for plasma TCA precipitable radiolabel, plasma sT4 concentration by a gp120 domain specific Leu3A ELISA (as a measure of sT4 functional activity), and total sT4 antigen by a non-specific polyclonal anti-sT4 ELISA in plasma.
Results. Following administration of SK&F sT4, the plasma concentration time profiles based on Leu3A and non-specific ELISA were similar, and displayed two elimination phases. Based on Leu3A ELISA, the mean $t_{1/2}\alpha$ was 17.24 min and mean $t_{1/2}\beta$ was 66.56 min. The mean ± SD plasma systemic clearance (Cls) and volume of distribution at steady state (VDss) were 1.80 ± 0.19 ml/min/kg and 53.8 ± 9.8 ml/kg, respectively. The mean AUC in the α-phase represented the majority (93.3%) of the total AUC from time zero to infinity. Consequently, most of the sT4 was eliminated in the α-phase. Based on polyclonal anti-sT4 ELISA, the mean $t_{1/2}\alpha$ was 16.75 min and mean $t_{1/2}\beta$ was 69.03 min. Elimination of plasma TCA precipitable radiolabel was also biphasic, with a $t_{1/2}\alpha$ of 13.3 min and a prolonged $t_{1/2}\beta$ of 169.2 min. The %AUC of TCA precipitable radiolabel in the β-phase was 76.5%. Plasma sT4 concentrations measured by either ELISA accounted for 80-100% of TCA precipitable radiolabel during the initial 30 min post dose, but represented less than 3% of TCA precipitable radiolabel by 180 min. The VDss was similar to the plasma volume of monkeys, suggesting that extravascular distribution is kinetically insignificant. Results also suggest that SK&F sT4 is metabolized rapidly to inactive molecules that have longer circulating half-lives than the parent molecule.
Conclusions. Although sT4 has a relatively small systemic clearance in cynomolgus monkey, it also displays an extremely small volume of distribution which together result in a short biological half-life. These studies suggest that the sT4 half-life in man may also be very short, and continuous infusion would be required to establish and maintain a desired blood concentration during sT4 treatment.

M.C.P.128 STRONG SYNERGISTIC ANTI-HIV ACTIVITY OF A PURINE AND A PYRIMIDINE NUCLEOSIDE ANALOG, ddI AND d4T

Brankovan, Vera*; Tarantini, K.*; Datema, R.**, and Chou, T.C.***
*Oncogen, Seattle, Washington, USA, **Bristol-Myers Company, Wallinford, Connecticut, USA, ***Memorial Sloan-Kettering Cancer Center, New York, NY, USA.

Objective. Assessment of potentially effective nucleoside combinations is essential for the development of successful anti-HIV therapies. Our objective was to evaluate the in vitro effects of combinations of dideoxydidehydeothymidine (d4T) and dideoxyinosine (ddI), both selective anti-HIV drugs, with respect to their anti-HIV effect and cytotoxicity.
Methods. CEM cells (lymphoblastoid T cell line) were infected with HIV, and exposed to varying concentrations of d4T, ddI and their combinations. After six days in culture, supernatants are analysed for p25gag viral protein. The toxicity is determined in uninfected CEM cells by ^{3}HTdR incorporation. The results are expressed as virus effective dose (ED_{50}), toxic dose (TD50), selectivity index ($SI=TD_{50}/ED_{50}$), and combination index (CI). The CI values of <1, $=1$, and >1 indicate synergy, additivism and antagonism respectively (Chou, J., and T.C. Chou, Elsevier Science Publishers, 1986).
Results. The ED_{50} for d4T, ddI and d4T+ddI were 5, 32 and 0.2 uM. The TD_{50} values for d4T and ddI were >100 uM, while d4T+ddI was 730 uM. The combination indices for d4T+ddI were CI_{ED50} was 0.024, and CI_{TD50} was 2.2. These results indicate that the d4T+ddI combinations act synergistically to inhibit the HIV replication. The same drug combination is not synergistic in case of toxicity against CEM cells ($CI>1$).
Concluison. Our data show that the combination of d4T and ddI synergistically inhibit the HIV, while the same combination shows no synergistic toxicity against CEM cells. Since both d4T and ddI are potential new anti-HIV agents for in vivo use, these resulcs have important clinical implicaitons.

M.C.P.129 THE CONSTRUCTION AND CHARACTERIZATION OF IMMUNOTOXINS SPECIFIC FOR HIV-INFECTED CELLS.

Ghetie, Victor*; Till, M.A.*; Capon, D.**; Patzer, E.**; Uhr, J.W.*; and Vitetta, E.S.*.
*University of Texas Southwestern Medical Center, Dallas, Texas
**Genentech, Inc., South San Francisco, California, U.S.A.

Objective. The purpose of this work was to prepare three conjugates (immunotoxins) between recombinant CD4 (rCD4) and deglycosylated ricin A chain (dgA) that vary in the linkage between the two components and then to compare their structure, biological activity and *in vivo* behavior.
Methods. The conjugates were constructed with N-succinimidyl-S-thioacetate (SATA), N-succinimidyl-oxycarbonyl-A-methyl-A-(2-pyridyldithio)toluene (SMPT), or N-succinimidyl-(4-carboxy-cyclohexyl-methyl)-maleimide) (SMCC).
Results. All three conjugates have a Mr of 80 Kd and contain a single rCD4 and a single dgA molecule. The affinity constant of the rCD4-dgA conjugates for recombinant gp120 (rgp120) was approximately half that of the initial rCD4 (2 x $10^{8}M^{-1}$). Both conjugates prepared with a disulfide bond between rCD4 and dgA (SATA and SMPT) were equally toxic to HIV-infected H9 cells *in vitro* and 1000-fold less toxic to uninfected cells. The rCD4-dgA constructed with a thioether bond between the rCD4 and dgA (SMCC) was not toxic to HIV-infected cells even though it could bind to rgp120. In mice, the rCD4-SATA-dgA conjugate showed reduced nonspecific uptake in the liver and spleen as compared to rCD4-SMPT-dgA, but more rapidly accumulated (and presumably cleared) in the kidney than the SMPT-derived conjugate.
Conclusion. The results suggest that the rCD4-SATA-dgA would be the conjugate of choice for further development as a potential therapeutic reagent to treat HIV infection.

M.C.P.130 PHASE I STUDY OF 2'3'DIDEOXYINOSINE(ddI) ADMINISTERED TWICE DAILY TO PATIENTS WITH AIDS/AIDS RELATED COMPLEX

John Lambert*, Dolin R*, Seidlin M**, Knupp C***, McLaren C***, Reichman RC*, *University of Rochester, Rochester,NY, **NYU Medical Center,NY, ***Bristol-Myers Co., Wallingford,CT, and sponsored by NIAID ACTG, Bethesda, MD, U.S.A.

Objective: To determine the maximum tolerated dose (MTD) and pharmacokinetics of ddI in patients with AIDS or AIDS related complex (ARC).
Methods: In a phase I trial, ddI is being administered IV for 2 weeks and po for 8-15 weeks to patients with AIDS or ARC at escalating dose levels. Initial doses were 0.4 mg/kg IV q12h followed by 0.8 mg/kg po q12h, and have currently been escalated to 3.0 mg/kg IV and 6 mg/kg po, with additional escalations being planned until the MTD is reached. Clinical, pharmacokinetic, and laboratory parameters are being followed, including serial HIV cultures, serum p24 antigen and lymphocyte markers.
Results: 12 patients have been studied for 2-15 weeks, including 3 at the 3 mg/kg IV dose. ddI has been well tolerated at all dose levels without adverse clinical effects. There have been no significant effects on Hb, WBC, liver function tests, BUN or platelets, except for 1 subject at the initial dose level who developed thrombocytopenia, possibly related to ddI. Of patients followed for at least 10 weeks, 2/6 had an increase in CD4 cells/ml, from 106 to 160 and from 237 to 513, and one had a serum p24 antigen decrease from 215 pg/ml to 134. At 1.0 mg/kg IV and 2.0 mg/kg po, the Cmax was 980 and 812 ng/ml. The Tmax was 0.82 hrs after oral dosing.
Conclusion: Up to doses currently administered, ddI appears to be well tolerated in terms of both clinical and laboratory parameters. Comparable plasma concentrations are achieved when twice the IV dose is given orally. Additional dose escalations to reach the MTD are underway.

M.C.P.131 DEVELOPMENT OF AN IN VITRO HUMAN MONOCYTE-DERIVED MACROPHAGE (MDM)-BASED SYSTEM FOR DRUG SCREENING AGAINST HIV-1

Polsky, Bruce*; Baron, P.A.*; Gendelman, H.E.**; Gold, J.W.M.*; Chou, T.-C.* and Armstrong, D.*.
*Memorial Sloan-Kettering Cancer Center, New York, New York, USA,
**The Henry M. Jackson Foundation, Uniformed Services University of the Health Sciences, Bethesda, Maryland, USA.

Objective. To develop a human MDM-based system for assessing in vitro anti-HIV-1 activity of candidate drugs for the treatment of HIV infection.
Methods. MDM-enriched populations of peripheral blood leukocytes from HIV-seronegative donors prepared by elutriation or adherence were seeded in 24- or 96-well plates, preincubated for 1 hour in the presence of 10-fold dilutions of experimental drugs, and infected with a monocytotropic HIV-1 isolate (HIV_{Ada}). Culture supernatants were serially assessed for p24 antigen by ELISA-capture.
Results. AZT, phosphonoformate (PFA), and 3'-fluorothymidine (3'-F-TdR) strongly inhibited HIV-1 infection in MDM.

Compound	ED_{50} range (uM)
AZT	0.015-0.139
PFA	5.27-11.63
3'-F-TdR	0.026-0.088

No cytotoxicity attributable to the drugs was observed.
Conclusions. In vitro anti-HIV-1 activity of experimental drugs may be rapidly assessed in this human MDM-based system. HIV-1 infection of MDM is inhibited by concentrations of these drugs reported effective in T-lymphocyte cultures.

M.C.P.132 POLYVINYL ALCOHOL MEMBRANE PERMEABILITY CHARACTERISTICS OF ZIDOVUDINE

P. Andrew Pearson, DL Blandford, ML Maliszewski, TJ Smith
Dept. of Ophthalmology, University of Kentucky, Lexington, Kentucky, USA.

Zidovudine (Retrovir) is an anti retroviral drug that is active against human immunodeficiency virus (HIV). It is a thymidine analogue that interferes with the HIV viral RNA dependent DNA polymerase and thus inhibits viral replication. In order to function in this way the drug must be constantly available for incorporation by the virus. Tissue culture studies have suggested that low levels (0.13ug/ml) of Retrovir are effective in blocking replication of HIV. These studies have also demonstrated toxic effects to bone marrow cell lines at levels of 1.25ug/ml. The drug is rapidly metabolized and excreted resulting in a serum half-life of about 1 hour. In order to sustain levels throughout the day relatively large oral or intravenous doses must be given. This method of drug delivery has the potential for toxic peak and subtherapeutic trough drug levels. There is no evidence that periodic pulsing of drugs that act as blockers of viral replication is necessary or helpful. An ideal type of delivery system would achieve a sustained therapeutic level which does not reach toxic or fall below effective levels. We have been investigating the permeability characteristics of Retrovir through polyvinyl alcohol (PVA) membranes. PVA membranes were prepared from 2% (w/v) PVA and then heat treated at 200 C for 2 hours to alter the permeability characteristics of the membrane. Diffusion cell studies demonstrate zero order release of Retrovir through heat treated PVA membranes. We believe that a PVA membrane based delivery system may be useful for obtaining therapeutic, non-toxic levels of Retrovir in AIDS patients.

M.C.P.133 EFFECT OF ORGANIC ARSENICALS ON PRODUCTIVE INFECTION OF HIV.

Gupta, Phalguni; O'Marro, S.; Rinaldo, C.R. and Ho, M.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To study the anti-HIV effect of oxophenarsine and other structurally related organic arsenical compounds.
Methods. Various concentrations of arsenical drugs were added to the culture medium after infection of H9 cells or PHA-stimulated lymphocytes with HIV. Production of HIV was monitored by the antigen capture test. The effect of drugs on the production of HIV from persistently infected H9 cells was monitored not only by the antigen capture test, but also by reverse transcriptase and infectivity assays.
Results. Oxophenarsine, a trivalent arsenical compound, in concentrations as low as 0.035 ug/ml, inhibited in vitro infection of blood lymphocytes and H9 cells by HIV. The drug also blocked the production of HIV from lymphocytes of seropositive men cocultivated with PHA-stimulated normal donor lymphocytes and depressed the production of HIV from the persistently infected H9 cell line. Zidovudine, the only FDA-approved anti-HIV drug, had no antiviral effect in cells persistently infected with HIV. Seven other pentavalent organic arsenicals whose structures are very similar to oxophenarsine were also tested for their in vitro anti-HIV properties. Of these seven compounds, one compound had identical organic structure as oxophenarsine except that it carried pentavalent, instead of trivalent, arsenic. However, none of these seven drugs had an anti-HIV effect in H9 cells.
Conclusion. Oxophenarsine is a potent anti-HIV drug. Oxophenarsine is a U.S. FDA approved drug for the treatment of syphilis. It was used extensively before the discovery of penicillin. Presence of trivalent arsenic in oxophenarsine may be crucial for its anti-HIV property.

M.C.P.135 CARBOCYCLIC OXETANOCIN ANALOGUES THAT INHIBIT DE NOVO REPLICATION OF HUMAN IMMUNODEFICIENCY VIRUS IN T-CELLS AND MONOCYTES/MACROPHAGES IN VITRO.

Hayashi, S*., Norbeck, DW**., Plattner, J*., Broder, S*., & Mitsuya, Hiroaki*. *National Cancer Institute, Bethesda, MD; **Abbott Laboratories, Abbott Park, IL, USA.

Objective. Two newly synthesized carbocyclic oxetanocin analogues, ±9-[2',3'-bis(hydroxymethyl)-1'-cyclobutyl]adenine (cA) and ±9-[2',3'-bis(hydroxymethyl)-1'-cyclobutyl]guanine (cG), were tested for activity against the infection of human immunodeficiency virus (HIV) in vitro.
Methods. In an HIV cytopathic effect inhibition assay, target $CD4^+$ T-cells were exposed to HIV-1 or HIV-2, cultured with/without drugs, and the viable cell number was determined. The expression of p24 gag protein and proviral DNA synthesis were also assessed.
Results. Both compounds, cA and cG, were found to be capable of protecting T-cell lines against the infectivity and cytopathic effect of HIV-1; inhibiting the expression of p24 gag protein; and suppressing the proviral DNA synthesis in vitro at concentrations 50-100μM. These compounds also inhibited the in vitro infectivity of HIV-2. Moreover, both cA and cG virtually completely suppressed the p24 gag protein expression in monocytes/macrophages exposed to monocytotropic HIV-1 at a concentration of 0.5μM. It was noted, however, that cA and cG exerted a substantial toxicity against target T-cells as well as normal periphearl blood mononuclear cells at around 100μM. The anti-HIV activity of cG was readily reversed by 2'-deoxyguanosine, but that of cA was hardly reversed by 2'-deoxyadenosine or 2'-deoxycytidine.
Conclusion. Our observations should provide new structure/activity relationships for carbocyclic nucleoside analogues which may be of value in developing a new class of experimental drugs for the therapy of HIV-related diseases.

M.C.P.137 PHASE I STUDY OF THE ADMINISTRATION OF RECOMBINANT SOLUBLE CD4 (rCD4) BY CONTINUOUS INFUSION TO PATIENTS WITH AIDS OR ARC

Yarchoan, Robert*; Thomas RV*; Pluda JM*; Perno CF*; Mitsuya H*; Marczyk KS*; Sherwin SA**; and Broder S*.
*National Cancer Institute, NIH, Bethesda, MD, USA, **Genentech, Inc., San Francisco, USA.

Objective. To investigate the toxicity, clinical effects, serum levels, immunologic effects, and virologic effects of rCD4 given by continuous infusion to patients (pts) with AIDS or ARC.
Methods. 12 patients with AIDS or ARC were administered rCD4 by continuous infusion for 15 days (after a 24 hr test infusion). 3 pts each received 1, 10, 30, or 100 μg/kg/day.
Results. No toxicity was observed other than phlebitis in 2 pts at their IV sites. Serum rCD4 levels were as follows: 1 μg/kg/day - 0.9 to 2.9 ng/ml; 10 μg/kg/day - 10 to 22 ng/ml; 30 μg/kg/day - 23 to 30 ng/ml; (other results pending). No antibodies to CD4 were detected in patients who received 1 to 30 μg/kg/day (other results pending). No changes were observed in the total WBC. No consistent changes were observed in the T4 cells, T4/T8 ratio, *in vitro* T cell proliferation to soluble antigen (Ag) , skin test reactivity, or serum HIV p24 Ag in patients receiving 1, 10, or 30 μg/kg/day rCD4. However, 2 of the 3 patients receiving 100 μg/kg/day had rises in their T4 cells (from 69 to 152 T4 cells and from 147 to 223 T4 cells/mm3 respectively). One of those 3 patients had detectable serum p24 Ag at entry: this fell from 401 to 245 pg/ml while on rCD4. Additional patients are now being studied at higher doses of rCD4 and for longer periods of time.
Conclusion. Because of the lack of observed toxicity and the suggestion of possible anti-HIV activity at the highest dose tested, additional testing of rCD4 by continuous infusion at 100 μg/kg/day and higher doses is warranted. From a theoretical point of view, continuous infusion may deserve special attention as a technology for administering rCD4.

M.C.P.134 NOVEL GLUCOSIDASE INHIBITORS AS ANTI-HIV AGENTS

Hiroyuki Shimizu*; Morikawa,S.*; Yamamoto,H.**; Ushijima,H.* and Kitamura,T.*
*National Institute of Health, Musashimurayama, Tokyo, Japan, **Pharmaceutical Research Laboratories Meiji Seika Kaisha, LTD., Yokohama, Kanagawa, Japan.

Objective. To evaluate the effect of novel glucosidase inhibitors, deoxynojirimycin(DNM) derivatives, on the replication of HIV-1.
Methods. DNM derivatives were newly synthesized,and were assessed the inhibitory effect on giant cell formation by Molt-4 cells and Molt-4/HIV-1 cells. The infectivities from Molt-4/HIV-1 or U937/HIV-1 cultured in the presence of drugs were also determined by using MT-4 cells. The envelope glycoproteins from Molt-4/HIV-1 treated with drugs were analysed .
Results. Some DNM derivatives showed the inhibition of HIV-induced giant cell formation at concentrations that were not cytotoxic. ND900 or ND1025 inhibited giant cell formation at about 10-fold lower concentration than DNM did. The infectivities of HIV-1 from Molt-4/HIV-1 or U937/HIV-1 were remarkably reduced in the presence of ND1025. In Molt-4/HIV-1 cells,ND1025 inhibited the processing of envelope glycoproteins. The electrophoretic mobility of virion-associated glycoproteins in the culture supernatant were also affected by ND900 or ND1025.
Conclusion. These synthetic DNM derivatives have potent anti-HIV activities in vitro. Effect of these sugar analogues is likely to depend on the inhibition of the envelope glycoprotein processing.

M.C.P.136 NEW ANALOGUES OF 2',5'-OLIGOADENYLATE WITH IMPROVED ANTI-HIV-1 ACTIVITY *IN VITRO*.

Montefiori, David C.*, Suhadolnik, R.J.**, Sobol, R.W., Jr.**, Reichenbach, N.L.**, Charubala, R.***, Pfleiderer, W.***, Robinson, W.E., Jr.*, Modliszewski, A.*, Altmeyer, B.*, Hubbard, B.* and Mitchell, W.M.*. *Vanderbilt University, Nashville, TN, 37232; **Temple University, Philadelphia, PA, 19140; and ***Fakultat fur Chemie, Universitat Konstanz, Konstanz D-7750, West Germany.

Objective. To screen structural, stereochemical and combination structural/stereochemical 2',5'-oligoadenylate (2-5A) and 3',5'-oligoadenylate (3-5A) analogues for anti-HIV activity.
Methods. Cell toxicity and *in vitro* anti-HIV-1 activity were determined in an MT-2 cell, microtiter cytopathic effect assay utilizing virus obtained from cultures of H9/HTLV-IIIa cells. Inhibition of reverse transcriptase (RT) activity was determined using a Triton X-100 activated viral lysate.
Results. A trimer of 2',5'-adenylate having the hydroxyl moiety replaced with a hydrogen atom at the 3' position of the middle residue (i.e., 3'-deoxyadenosine or cordycepin) demonstrated potent (compared to AZT) concentration-dependent antiviral activity at 4-32 uM without toxicity to the cells. This trimer also exhibited concentration-dependent inhibition of HIV RT. Other analogues exhibited various degrees of activity or were inactive in these assays.
Conclusions. The extent of 5'-phosphorylation, length of oligomer, type of internucleotide linkage, and the presence or absence of deoxyadenosine and stereoconfiguration are all critical factors for anti-HIV activity of this class of compounds.

M.C.P.138 METRONIDAZOLE (M) TRICHOMONIASIS (T) ERADICATION AS POSSIBLE POTENT IMMUNITY RESTORING PROCEDURE IN AIDS.

Krvavac Šukrija;Rustembegović A.
University and Medical Center,Women's Health Institute,Sarajevo,Yugoslavia

Duesberg's firm convinction about nonviral cause[1] of AIDS is in complete accordance with recently exposed[2] AIDS conception of subepithelial T as the most frequent,but since now neglected initiator and/or supporter of immunosuppression.
Regarding the existence of cross-immunity by all three known trichomonal species (Trichomonas vag.,Tr.intestinalis and Tr.oralis),it seemed to us logically to suppose that,if the host get freed from the pressure of trichomonal antigens on its immune apparatus,it will be easier to resist to other antigens.Because of that,we have determined T4/T8 by 7 patients with symptomatic genital T before and after M therapy.
As positive effect of M shouldn't be attributed to repression of anaerobic bacteries,patients without noticeable focuses with such bacteries had been chosen.
An positive effect have been realised,i.e.increasing of that indicator of immune status.Similar positive effects of M on immune status had been noticed by experimental animals[3] but without dete about eventual (intestinal) trichomoniasis of animals.
Regarding frequent T,supra- or infra-epithelial locations (taking together all human species), as well as their very large antigenic repertoire,we think that those strong immunogenic agenses can be at least partners to viruses in etiopathogenesis of AIDS.Accordingly,and undependently of possible dilemma what primary and what secondary immunosuppressive AIDS agent,authors think that careful use of M,with consequent T eradication,may have restorative efect on immune status of AIDS patients and risk groups.

M.C.P.139 A USEFUL IMMUNOTHERAPY IN AIDS.

MARICHAL Bernard J., M.D.,JENAER M.C., BRUSSELS BELGIUM

In a clinical study made in Africa upon 90 patients-AIDS or ARC, 26 had at least one year of immunotherapy at the end of 1988. This immunotherapy is using different products: nucleic Acids, cyclosporin and an anti heavy gamma chain. The particularity of this treatment (Tt) is the use of very small doses of each product. The results are compared with those of a group without any immunotherapy. In both groups, the O.I. are treated by the classical medication. No one patient in the study is or has been on AZT, or other specifical anti AIDS medication.

The results are:

		Africans(noTt)	Africans on Tt	Personal European cases (4)
diarrhea (1)		40	6	-1
Fever (1)		13	5	2
Infections (1)		55	13	14
Biology (2)	absolute T4	-4	191	51
	T4/T8	23	40	61
Weight (3)		-14	+3	+1

(1) Frequency of diarrhea, fever, infections in %.
(2) In % expressed macimal relative enhancement of T4 and T4/T8
(3) Middle evolution of the weight, in Kg/year.
(4) Group added in order to compare the biological data with those of the AZT studies. When compared with the clinical studies, on AZT, the biological results of the european group are reaching the same level of efficacy.

Key words: immunotherapy, small doses, cyclosporin, nucleic Acids, anti heavy gamma chain.

M.C.P.140 A MODEL OF AIDS-VIRUS DISINFECTION

Luben G. Angeloff

Angel's Biomedical Laboratories, Ltd., P.O. Box 122, Station "Place du Parc", Montreal, Quebec H2W 2M9, Canada

A virus disinfection was observed by the author in 1930-39 in water buffalo (Bubalus bubalus, Linn.) in Kosevci, Bulgaria, that all those animals who ate wild sour-apples did not get the infection caused by the ultr-virus aphthae (Aphthae epizooticae). Later, the author applied above observations as model on rats bearer ascites Novikoff (Hepatoma) tumor (3rd Asian Cancer Conference (Abs. 143), p. 126, 1977.

In these investigations as model disinfectors alkaline Bulgaros 26L-a (0.1M NaOH), acidic Bulgaros 26L-b (0.1MHCl), and acidic Bulgaros 26L-c (0.1M H_2SO_4) on normal white Wister female rats were used as follows: (a) three rats were injected Sc with a single dose of Bulgaros 26L-a (0.1M NaOH) 1ml/100g.b.wt.; (b) five rats were injected Sc with Bulgaros 26L-b (0.1M HCl) 1.5ml/100g.b.wt.; and (c) five rats were injected Sc with Bulgaros 26L-c (0.1M H_2SO_4)1.5ml/100b.wt. The concentrations of above disinfectors were well tolerated by the recipients and after 24h. all rats were sacrificed and their heart and liver were examined and they were like normal. The results showed that Bulgaros 26L-a-c might be applied as disinfectors against various viral and bacterial infections. Copyright 1989 by Luben G. Angeloff.

M.C.P.141 CONCENTRATION DEPENDENT DUAL EFFECTS OF THE MONOLAURYL ESTER OF SUCROSE (L.S.) ON THE ANTIFUNGAL ACTIVITY AND ABSORPTION SPECTRA OF AMPHOTERICIN B (AmB).

Brajtburg, Janine*; Gruda, I.** and Medoff, G.*
*Washington University School of Medicine, St. Louis, Missouri, USA,
**Universite du Quebec a Trois-Rivieres, Trois-Rivieres, Quebec, Canada.

Objective. To develop a system for AmB drug delivery.
Methods. Comparison of effects of a mild detergent, L.S. oq AmB-induced decrease in cellular K^+ retention and viability of Saccharomyces cerevisiae and Cryptococcus neoformans cells with L.S. effects on AmB physical state as reflected by absorbtion spectra.
Results. L.S. at concentrations 0.008% to 0.03% enhanced the toxic effects of AmB on the two fungi. In contrast, concentrations 0.06% to 2.5% inhibited AmB effects. We analyzed changes in AmB absorbtion spectrum induced by L.S. at these two concentration ranges by comparing ratios (R's) of AmB absorbance at 409nm, the wave length characteristic of non aggregated (monomeric) AmB, to absorbance at 328nm, the wavelength characteristic of aggregated AmB. Low concentrations of L.S. caused a decrease in R. and the higher L.S. concentrations increased in R.
Conclusion. L.S. had concentration dependent dual effects on antifungal action of AmB which correlated with shifts in the physical states of AmB between its monomeric and aggregated forms. Since the inhibitory concentrations of L.S. on the antifungal effects of AmB were about 1000 times greater than those reported previously for inhibition of AmB toxicity to mammalian cells, this suggests that L.S. may be useful as a vehicle for improvement of AmB delivery. Moreover, increase in AmB toxicity induced by low concentrations of L.S. suggests the possibility that synergistic interactions between fatty acid esters, and polyene antibiotics may have therapeutic value.

M.C.P.142 SEROLOGIC AND IMMUNOLOGIC PARAMETERS IN A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL OF AMPLIGEN ADMINISTERED TO SUBJECTS WITH HIV INFECTION

McKinley, G.F.; Reddy, M.M.; Inada, Y.; Ong, Kenneth; O'Connor, J.J.; Grieco, M.H.
St.Luke's-Roosevelt Hospital Center, Columbia University, New York City 10019 USA.

As part of a multicenter trial of intravenously administered AMPLIGEN (mismatched, double-stranded RNA) we enrolled 25 HIV-seropositive subjects (asymptomatic or early ARC) and followed them for up to 36 weeks. Blood was taken at the start of study and at weeks 4, 12, 24, and 36. At study end it was found that 12 patients had been given placebo and 13 had received AMPLIGEN 400 mg twice weekly. There were no statistically significant differences between groups with respect to soluble CD8, soluble IL-2 receptor, beta-2 microglobulin, and neopterin.

	AMPLIGEN (n=13)				PLACEBO (n=12)			
WK	sCD8 (U/ml)	sIL 2R (U/ml)	B2-M (ug/ml)	Neopt (ng/ml)	sCD8 (U/ml)	sIL-2R (U/ml)	B2-M (ug/ml)	Neopt (ng-/ml)
00	985±093	1385±069	4008±414	3.6±0.4	638±064	1292±116	2583±372	3.0±0.2
04	930±090	1396±062	3358±270	4.3±0.5	785±080	1246±099	3114±355	3.8±0.4
12	979±115	1369±072	3815±398	5.5±0.8	760±078	1230±110	3127±416	3.7±0.5
24	838±186	1159±134	4179±533	4.2±0.9	645±068	1178±117	3000±358	3.3±0.4

There were no statistically significant differences with respect to circulating immune complexes (measured by the inhibition of immune adherence), erythrocyte complement C3b receptor (E-CR1) activity, and direct Coombs' test.

M.C.P.143 TREATMENT OF THERAPY-RESISTENT ORO-PHARYNGEAL CANDIDIASIS WITH FLUCONAZOLE IN HIV-1-INFECTED PATIENTS

Tschechne, Barbara; Brunkhorst, U.; Schedel, I. and Deicher, H.
Hannover Medical School, Hannover, F.R. Germany.

Objective. To evaluate the effectivity of fluconazole, an experimental azole antifungal agent is effective in therapy of therapy-resistent oro-pharyngeal candidiasis in HIV-1-infected patients.
Methods. 20 patients with therapy-resistent oro-pharyngeal candidiasis were treated with fluconazole at daily doses of 50-100 mg for 21 days. Patients were weekly examined for clinical symptoms as well as side effects and haematological and organ toxicity of the drug. Mycological assessment included microscopical examination and culture (cfu/ml) of mouth washings.
Results. Resolution of symptoms and signs was obtained in the first week of treatment in 18/20 patients. Partial improvement was observed in another 2/20 patients. Mycological assessment showed a significant reduction of candida cultures of mouth washings. In 60% of the patients the culture tests became negative at end of therapy whereas in 40% of patients more than 10^2 cfu/ml were found. More than 60% of the patients had a clinical relaps four weeks after stopping the experimental therapy with fluconazole. No alteration of liver tests nor nephrotoxicity was observed.
Conclusion. Fluconazole was shown to be a highly effective drug in the treatment of therapy-resistent oro-pharyngeal candidiasis in HIV-1-infected patients. A continuous therapy seemed to be necessary to avoid clinical relaps. Optimal dosage remain to be defined in further studies.

M.C.P.144 INHIBITION OF HIV-REVERSE TRANSCRIPTASE BY A KAMPO MEDICINE, SHO-SAIKO-TO

Ono, Katsuhiko*; Nakane, H.*; Fukushima, M.**; Chermann, J.-C.*** and Barré-Sinoussi, F.****
*Research Institute and **Hospital, Aichi Cancer Center, Nagoya, Japan,
***Laboratoire de Recherches sur les Restrovirus et Maladies associées, INSERM, Marseille and ****Laboratoire de Biologie des Retrovirus, Institut Pasteur, Paris France

Objective. To describe the *in vitro* inhibitory effect of a well-known kampo medicine (Chinese drug), Sho-Saiko-To, on the activity of HIV-reverse transcriptase.
Methods. Reverse transcriptase activity was measured *in vitro* with $(rA)_n \cdot (dT)_{12-18}$ as the template·primer and [^{3}H]dTTP as the triphosphate substrate, and the effect of the drug was evaluated by adding various concentrations of Sho-Saiko-To.
Results. The activity of HIV-reverse transcriptase was inhibited by more than 70% in the presence of 200 μg/ml Sho-Saiko-To. The inhibition was dose-dependent, and the drug inhibited the enzyme activity by 90% at 500 μg/ml which is a clinically attainable concentration. Of the seven ingredients of Sho-Saiko-To, the extract from radix of a plant, Scutellariae, was found to have strong inhibitory effect on the reverse transcriptase activity at concentrations less than 50 μg/ml. In contrast to reverse transcriptase, cellular DNA polymerases α, β and γ were much less sensitive to inhibition by this drug, supporting the fact that Sho-Saiko-To is non-toxic to the host cells.
Conclusion. Sho-Saiko-To is promising as a candidate for antiretroviral agent.

M.C.P.145 VIRAL INHIBITION THERAPY AGAINST AIDS (VITA)

Joshi, S*; Van Brunschot, A.; Robson, I. and Bernstein, A.**
*Faculty of Medicine, University of Toronto, Ontario, Canada.
**Mount Sinai Research Institute, Toronto, Ontario, Canada.

Objective. *Gene "manipulation" of stem cells leading to the development* of an HIV-resistant immune system.
Methods. Various retroviral vectors expressing antisense or sense RNAs to HIV-1 were constructed. The vector particles were used to infect CD4$^+$ lymphocyte- and macrophage-derived cell lines. These transformants will soon be challenged by HIV-1 and the virus production will be monitored.
Results. The ability of various vectors expressing sense or antisense RNAs to interfere with the HIV-1 multiplication will be reported. The use of antisense RNA is only one way to interfere in the life cycle of HIV-1. Other vectors to express various proteins interfering with the HIV-1 life cycle are under way. The best of these vectors conferring resistance to HIV-1 will be used to transform human bone marrow stem cells.
Conclusion. If a stem cell could be made resistant to HIV-1, then upon maturation and development it will lead to the reconstitution of an HIV-1 resistant immune system. Both T-lymphocytes and macrophages, the primary targets of HIV-1 infection, derive from the bone marrow stem cells. The introduction into these stem cells of retroviral constructs expressing RNA or protein molecules conferring resistance against HIV-1 infection provides a potential therapeutic approach towards the development of an HIV-1 resistant immune system.

M.C.P.147 MENAQUINONE (BACTERIAL VITAMIN K) INHIBITS HIV-1 INDUCED SYNCYTIA FORMATION BUT NOT HIV-1 REPLICATION

Qualtiere, L.F.; Zbitnew, A.; Meise-Qualtiere, J.M. and Conly, J., Dept. of Microbiology, University of Saskatchewan, Saskatoon, Sask., Canada.

OBJECTIVE: To determine if napthoquinone (Vitamin K series) compounds can affect HIV-1 induced syncytial formation and/or replication.
METHODS: Physiological non-toxic concentrations of phylloquinone menadione and menaquinone-7 (MK-7) were added to cultures of MT-2 and Hut-78 cells infected with three different clinical isolates of HIV-1. AZT was utilized as a comparative compound. The effect of these chemicals were evaluated by inhibition of syncytial formation, and viral antigen production (Reverse Transcriptase assay and indirect immunofluorescence).
RESULTS: Remarkably, MK-7 a bacterially produced Vitamin K at concentrations between 5 and 1 ug per ml, inhibited syncytia formation in MT-2 infected cells similar to AZT at 5 to 1 ug/ml. Similar inhibition of syncytia formation was also observed in HIV-1 infected Hut-78 cells, however, while AZT effectively limited HIV replication, MK-7 had no effect whatsoever on virus production.
CONCLUSION: Further studies are warranted on the effects of menaquinone induced inhibition of syncytia formation especially in light of the findings that concurrent effects of HIV antigen and virus production are not affected in these cells. If syncytia formation is indeed an important factor in HIV pathogenesis then the understanding of the mechanism of inhibition of syncytia formation by MK-7 may prove a valuable way of limiting HIV-1 spreading in vivo.

M.C.P.149 AIDS : IS A SAFE VACCINE READILY AVAILABLE ?

Norman GODIN, M.D. Consultant Geneva University Hospital
14, Quai du Seujet, 1201 Genève, Suisse

Objective : Finding the best and safest method to obtain a marketable AIDS vaccine.
Method : Analysis of present vaccine strategies to obtain an AIDS vaccine. Development of a new concept in order to obtain a new kind of vaccine.
Result : Largely two main strategies for developing an AIDS vaccine are now being pursued. The first one starts with the antigen, usually synthetic fragments of HIV (gp 120, gp 160, etc...) obtained by genetic engineering.
The second one consists of developing an antiidiotypic vaccine using selected monoclonal antibodies (mAbs) to the CD4 receptor. Both strategies intend to obtain specific antibodies or cellular immunity to HIVs.
However, because of competition and crossreactivity between HIV and the physiological ligand for the CD4 receptor, namely MHC II, blocking HIVs with a classical vaccine will at the same time block MHC II binding to CD4 and interfere with normal macrophage to T cell interaction causing immunosuppression.
To overcome these difficulties, a new type of "vaccine" consisting of monoclonal antibodies, liposomes and adjuvant intending to safely mimic HIV infection and stimulate NK cells (non MHC restricted immune response) is being considered.

Conclusion : A new concept for an AIDS vaccine based on stimulation of NK cells is presented.

M.C.P.146 EFFECT OF PEPSIN TREATMENT ON THE HIV ENVELOPE AND CORE ANTIGEN

Ujhelyi, E.*, Füst, G.*, Illei, G.*, Allam, S.**, Szelényi, J.*, and Hollán, S.R.*
*Natl. Inst. Haematol. Blood Transfusion, Budapest, Hungary, and **Abbott GmbH Diagnostics, Delkenheim, FRG

Objectives. Previously (Ujhelyi et al., AIDS 1,161,1987) we worked out a method for measuring the amounts of anti-core and anti-env antibodies hidden in circulating immune complexes. The method is based on the pepsin digestion of isolated immune complexes. In order to clarify whether HIV antigens are destroyed during this treatment, the pepsin sensitivity of purified recombinant env and core antigens was investigated. Methods. Purified p24 and gp41 recombinant antigen preparations were dialysed against an acetate buffer, pH 3.9, digested with pepsin for 16 h at 37°C (enzyme/substrate ratio: 1 to 5) and neutralized. Antigenecity of the core preparations was measured by the Abbott antigen assay and Western blot whereas that of the env preparations was estimated using a new antibody-inhibition assay. Results. Core preparation was found to be extremely pepsin-sensitive. By contrast, the antigenecity of the purified env preparation was not destroyed but dose-dependently increased after pepsin treatment. Conclusion. The different sensitivity to pepsin digestion of HIV antigens may point to a difference in their sensitivity to other proteases influencing the in vivo processing of the antigens.

M.C.P.148 *THE EFFECTS OF TRADITIONAL MEDICINE(SHO-SAIKO-TO:SST) ON PERIPHERAL MONONUCLEAR CELL (PMC) FROM AIDS & ARC PATIENTS*

Watanabe,Kazuhito; Inada,Y.; Ikegami,H.; Lange,M.and Clark,W.S.
St.Luke's-Roosevelt Hospital Center, Columbia University, New York,NY,USA

Objective:We have studied effects of SST on blastformation assay in PMC from patients with AIDS(n=40) and ARC(n=44), and healthy heterosexuals(HH,n=20)
Methods:PMC were cultured with or without each mitogen(PHA,Con A,PWM) in the presence or absence of SST (20ug/ml). Proliferation was measured by ^{3}H-thymidine uptake after 96 hrs incubation.
Results:Table shows proliferation response(PR,Ave.in cpm) of 3 groups with or without SST. Each patient group was further subdivided into a responder and nonresponder group based on positive or absent response to the combination of SST and PWM. As previously reported, major decreases in PR were observed in response to PWM only for ARC and AIDS. SST enhanced proliferative activity itself in all 3 groups and enhanced PR to PWM in 34/44 ARC and 22/40 AIDS. It is of interest that the greatest enhancing response of SST on PWM-PR was observed in PMC's from ARC, and occurred maximally in those exhibiting the combination of (i)lowest PR to PWM and (ii)normal PR to Con A. The percentage increases observed for the same combination in AIDS, on the other hand, were only similar to that seen in HH controls.

	Total			Mitogen & SST(%)			Responder/Nonresponder	
	HH	ARC	AIDS	HH	ARC	AIDS	ARC	AIDS
No.	20	44	40				34/11	22/18
No Mitogen	966	358	237	+30	+18	+13	323/477	294/168
PHA	23675	16201	8512	-15	-16	-12	16045/16733	9470/7341
Con A	13153	11525	3664	-18	-17	-19	11652/11091	4514/2626
PWM	5644	850	675	+13	+47	+8	733/1248	721/617

Conclusion:Our results suggest that SST is able to stimulate monocyte-T4 cell -B cell network system and/or suppress T8 cell function.

M.C.P.150 AFRICAN TRADITIONAL MEDICINE AND AIDS

CHIEF AJISEFINNI S.O.
19, Aramoko Road, Box 95, Ijero-Ekiti, Ondo State, Nigeria,

African Traditional Medicine is the use of herbs and parts of animals and birds. Traditional Medicine is the oldest known method of healing the sick. Most people in Africa have no alternative than traditional medicine.

The Western trained Medical Doctors and Traditional Healers should be partners in progress to find a common solution for the health of mankind. There should be provision of the traditional healer with a place in the AIDS NETWORK. Traditional healer is to educate the rural dwellers to know who has AIDS and how to avoid AIDS. My group consists of traditional medicine experts has started research into the preventive and cure for the killer disease - AIDS by using herbs and other ingredients. By GOD's Will there would be a positive result. AIDS is one disease which all races of humanity should cooperate to fight.

No time in the history of mankind have creatures as small as the AIDS virus caused so much grief and sorrow to so many people.

T.C.P.1

MEASUREMENT OF AFFINITY MATURATION IN HIV-1 INFECTED CHIMPANZEES, *Richard T Coughlin*, P. Bulger*, V.G. Masison*, D.J. Marciani* and J. Eichberg**, *Cambridge BioScience Corporation, Worcester, MA, USA, **Southwest Foundation for Biomedical Research, San Antonio, TX, USA.*

Objective. To quantitate the kinetics of affinity maturation in HIV-1 infected animals.
Methods. Over 20 sera for each of the three HIV infected chimps were obtained over a two year period. A modification of the method (Pullen, 1986) was used to measure the avidity of chimp sera for a rec. env. peptide and compared with conventional EIA on the same antigen.
Results. All three chimps showed an abrupt increase in titer starting 2-3 weeks after challenge. The titer reached a maximum between 50 and 100 days and then either declined or remained constant. Avidity increased steadily in all three animals over the two years. A plot of EIA titer vs avidity over the entire observation period revealed no significant correlation (r=0.02). When compared with a panel of HIV positive human sera, the EIA titers of the chimps at one year were slightly elevated but the avidity was significantly higher than the mean of the human sera.
Conclusion. EIA titer is an inappropriate measure of the antibody avidity. Infected chimps showed a steady increase in affinity for the envelope over two years. Chimps eventually produced higher avidity sera for the envelope than did a random selection of HIV-1 infected humans.

T.C.P.2

TYPE SPECIFIC CTL RESPONSE TO THE HIV-1 ENVELOPE GENE PRODUCTS

Birch-Limberger, Karen A*; Paradis, TJ*; Flexner, C**; Moss, B**; Schooley, RT*, and Walker, BD*. *Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA; **Laboratory of Viral Diseases, NIAID, NIH, Bethesda, MD, USA.

Objective. To determine group vs. type specificity of CTL directed at the HIV-1 envelope protein.
Methods. Peripheral blood mononuclear cells from HIV-1 seropositive individuals were cloned via limiting dilution in the presence of a CD3-specific monoclonal antibody (mAb) and recombinant IL-2. Developing clones were tested for cytolytic activity against autologous or allogeneic EBV-transformed B cell lines infected with HIV-vaccinia recombinant vectors in a 4 hour ^{51}Cr release assay. Ab competition assays were conducted by incubating target cells with mAb prior to the addition of effector cells.
Results. An HIV-1 envelope-specific CTL clone, designated 63D45, lyses target cells expressing the HTLV-IIIB envelope or the HTLV-IIIMn envelope up to 70% above control at an effector: target ratio of 2.5:1, but does not lyse target cells expressing the HTLV-IIIRF envelope. Lysis is restricted by the HLA class I antigen B8, and is abrogated by monoclonal antibodies to CD3 or CD8, but not CD4.
Conclusions. HIV-1 envelope-specific, HLA Class I restricted CTL are part of the host immune response to HIV-1 infection. This demonstration of a type-specific response to the HIV-1 envelope is an important consideration in design of subunit vaccine strategies.

T.C.P.3

AZT INHIBITS LPS-INDUCED SECRETION OF IL-1 BY CULTURED NORMAL HUMAN MONOCYTES.

Weiss, Laurence; Haeffner-Cavaillon, N.; Laude, M. and Kazatchkine, M.D.
Unité d'Immunopathologie, Hôpital Broussais, Paris, France.

The failure of 3'-azido-3'-deoxythymidine (AZT) to inhibit HIV replication in human macrophages is not dependent on the inability of the drug to permeate the cell membrane. Little is known however on the consequences of intracellular accumulation of the drug on monocyte function. The effect of AZT on the ability of unstimulated and LPS-stimulated human mononuclear adherent cells (MNC) to produce Interleukin-1 (IL-1) was investigated in vitro. MNC from normal donors were cultured in serum-free conditions with increasing amounts of Neisseria meningitidis LPS (0.01-10 µg/5 x 10^5 cells) for 24 h. AZT alone did not induce IL-1 production in cultured MNC. AZT did not interfere with the ConA comitogenic thymocyte assay for IL-1 activity in LPS-stimulated cultures. AZT inhibited the extracellular release of IL-1 activity in a dose-dependent manner although it dit not affect significantly the induction of cell-associated IL-1 activity by LPS. The latter finding correlated with the lack of effect of AZT on the induction of cell-associated IL-1 alpha antigen by LPS, as assessed by radioimmunoassay. Thus, AZT specifically inhibits the release of functional IL-1 beta by LPS-stimulated monocytes which may endow the molecule with anti-inflammatory properties.

T.C.P.4

ENHANCEMENT OF LYMPHOCYTE-MEDIATED, HIV SPECIFIC ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY BY BIOLOGIC RESPONSE MODIFIERS

Murayama, Tsugiya and Rinaldo, C.R.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To examine antibody-dependent cellular cytotoxicity (ADCC) mediated by peripheral blood mononuclear cells (PBMC) obtained from HIV-infected subjects, and enhancing effect by biological response modifiers (BRM) Picibanil (OK432 streptococcal preparation, Chugai, Japan) and interleukin 2 (IL-2).
Method. PBMC from homosexual men with known duration of HIV infection and from HIV seronegative controls were examined for ADCC activity against HIV-infected CEM.NKR cells (cell line resistant to natural killer activity) in a 4 hr ^{51}Cr-release assay. PBMC were precultured with Picibanil or IL-2 for 16 hr and then tested for ADCC activity. Serum from an HIV-seropositive homosexual man with ADCC activity was used as the source of antibody.
Results. HIV-specific ADCC activity of PBMC from HIV-seropositive homosexual subjects was significantly decreased in relation to duration of infection. The ADCC response was found to be significantly associated with numbers of CD4$^+$ T cells, and CD16$^+$ and Leu 19$^+$ NK cells. Additionally, ADCC activity of PBMC from HIV-seropositive and seronegative subjects increased 2-fold after pretreatment with Picibanil or IL-2. We are currently studying mechanisms of the enhancing effect of Picibanil pretreatment on ADCC activity.
Conclusion. Although PBMC from HIV-seropositive subjects can mediate ADCC, the response is impaired in association with duration of HIV infection. BRM-pretreated PBMC exhibited significantly greater ADCC activity than did untreated PBMC.

T.C.P.5

CD4+ AND CD8+ CYTOTOXIC T LYMPHOCYTE-MEDIATED LYSIS OF MACROPHAGES EXPRESSING HIV ANTIGENS

Torpey, III, David J.; Murayama, T.; Gupta, P. and Rinaldo, C
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To characterize cytotoxic T lymphocyte (CTL) lysis of macrophages expressing HIV antigens.
Methods. Autologous macrophages cultured in vitro for 6 days were either infected with recombinant vaccinia viruses (rVV, courtesy of Dr. B. Moss) containing HIV genes or coated with HIV, and used as target cells in a ^{51}Cr-release assay. Freshly-isolated PBMC or PBMC cultured for 6 days with UV-inactivated HIV plus IL-2 from HIV seropositive, asymptomatic individuals were depleted of CD16+ NK cells and used as effector cells.
Results. Antigen-stimulated CTL mediated a 28.5% mean virus-specific lysis of rVV-infected macrophages expressing env or gag antigens, which was several fold greater than lysis mediated by freshly-isolated, CD8+ effectors. Antigen stimulation activated HIV-specific, CD4+ CTL, in addition to augmenting CD8+ CTL. When macrophages were coated with either HIV III_B or HIV_{RF}, freshly-isolated effectors mediated a 6.5% mean virus-specific lysis; PBMC stimulated with HIV antigen demonstrated 8.8% mean lysis. PBMC from HIV seronegative subjects did not exhibit these responses.
Conclusions. Macrophages infected with rVV-env, rVV-gag, or whole HIV were lysed by CD8+, in vivo circulating CTL. An enhanced cytotoxic response occurred when PBMC were stimulated with HIV antigen, which activated CD4+ CTL. These results agree with our previous work (J. Immunol., 142(4), 1989) using herpes simplex virus-infected macrophages, and suggest that both CD4+ and CD8+ CTL are important in host immune response to HIV.

T.C.P.6

DIFFERENTIAL KINETICS OF HIV INFECTION OF BLOOD MONOCYTES AND MACROPHAGES IN VITRO AND EFFECTS OF SUBSEQUENT FUNCTIONS

Kazazi F., Mathijs J.M., Foley P., T.C. Sorrell and Cunningham A.L. Virology and Infectious Diseases Units, Westmead Hospital, Sydney, Australia.

Monocytes and macrophages are important sites of HIV infection, especially in brain and bone marrow. The state of differentiation and surface to which these cells adhered in vitro had a major effect on kinetics of HIV infection and function of the infected cells. HIV infection of recently adherent CD4 positive blood monocytes and five day adherent CD4 negative macrophages with three fresh monocytotropic HIV isolates showed two different kinetic patterns. HIV antigen and RT levels in infected monocyte cultures remained high for 3-4 weeks before detachment and necrosis of the cells occurred. Infection of macrophages (without M_CSF stimulation) generated much lower HIV levels and in 2 of 4 cultures these declined to undetectable over two weeks leaving persisting viable macrophages. 72% of monocytes and 8% of macrophages were infected at one week (by in situ hybridization). Anti-Leu 3a (CD4) monoclonal antibody almost totally blocked HIV infection of monocytes but had an incomplete or no effect on macrophage infection, suggesting the presence of an alternate receptor. Incubation of selected human anti HIV antisera with CD4 negative macrophages before infection with HIV had variable effects. Some sera had high neutralizing titres (1/100 - 1/1000) whereas others produced significant enhancement only when the effect of neutralization was discounted by preincubation with monoclonal antibody to anti FcRI. HIV infection of the blood monocytes but not macrophages inhibited presentation of herpes simplex or tetanus toxoid antigen to immune autologous T lymphocytes. A humoral heat stable inhibitory factor released by HIV infected monocytes has been identified and is being characterised.

T.C.P.7

IMMUNOTOXINS PREPARED FROM HUMAN MONOCLONAL ANTIBODIES COUPLED TO DEGLYCOSYLATED RICIN A CHAIN KILL HIV-INFECTED LINES OF T CELLS AND MONOCYTES

Zolla-Pazner, S[1,2]; Till MA[3]; Gorny MK[2]; Patton JS[4]; Uhr JW[3] & Vitetta ES[3]. [1]New York VA Hospital, [2]NYU Med. Ctr., New York, NY, [3]Univ. of Texas Southwestern Med. Ctr., Dallas, TX & [4]Genentech, San Francisco, CA. USA

OBJECTIVE: To determine whether immunotoxins (ITs) composed of human monoclonal antibodies (mAb) and Ricin A are capable of killing lines of HIV-infected T cells (H9) and monocytes (U937).
METHODS: Two human IgGk mAb specific for gp 41 were derived from EBV-transformed B cells from the blood of HIV-infected patients. mAb were coupled to deglycosylated Ricin A chain (dgA) via a heterobifunctional cross-linker. Either IT or human IgG-dgA was cultured with HIV-infected or uninfected H9 or U937 cells for 36 hr. and toxicity was assessed by pulsing cells with ^{3}H-thymidine for 6 hr.
RESULTS: While IgG-dgA did not kill infected H9 or U937 cells at concentrations less than 10^{-7} M, both ITs killed 50% of infected H9 cells at 1.5×10^{-9} M. Similarly, both ITs killed 50% of infected U937 cells at 5×10^{-9} M. Addition of chloroquine to U937 cultures markedly potentiated specific killing of HIV-infected U937 cells resulting in an IC_{50} of $4\text{-}6 \times 10^{-11}$ M. The specificity of killing was established by showing that both ITs could be blocked by rgp160 but not by rgp120 or human IgG. Neither IT was cytotoxic for Class II$^+$ Daudi cells at concentrations below 10^{-7} M.
CONCLUSIONS: ITs composed of human mAb to gp41 and deglycosylated Ricin A specifically kill lines of HIV-infected human T cells and monocytes.

T.C.P.8

SELECTIVE INFECTION OF MACROPHAGE SUBSETS IN THE LUNG BY HIV

Johnson, Margaret; Poulter, L. W. Royal Free Hospital, London, UK.

It is recognised that alveolar macrophages are a heterogeneous population. Subsets of this population can be distinguished by phenotypes using monoclonal antibodies. In HIV+ individuals the proportions of virus infected alveolar macrophages identified by the expression of viral proteins is seen to be a small proportion (2-10%) of total macrophage like cells in bronchoalveolar lavage (BAL). This study sets out to determine whether infection of alveolar macrophages is restricted to one phenotypically distinct subset or is indiscriminate. Sequential immunocytological techniques detecting viral proteins and discriminate antigens of macrophage subsets can be performed on cell spreads obtained from BAL of AIDS patients presenting with pneumonitis. Probes to gp120, P24 and P17 proteins will be used in conjunction with McAbs. EBM11 (detects all macrophages), RFD1 (identifying dendritic cells), RFD7 (identifying mature phagocytes), and UCHM1 (identifying monocytes). The distribution of gp120, P24 and P17 antigen expression on each of the populations of cells will be described. The proportions of each phenotypically distinct subset of macrophages expressing viral proteins will be quantitated by performing cell counts. Results presented will reveal whether there is a selective infection of a particular subset of cells and/or whether HIV infection alters macrophage antigen expression. As previous studies have shown a relationship between cell phenotype and function, this study will also reveal whether HIV infection might alter the functional capacity of alveolar macro phage populations.

T.C.P.9

NORMAL CAPACITY OF MONOCYTES FROM AIDS PATIENTS FOR UPTAKE AND GROWTH INHIBITION OF *MYCOBACTERIUM AVIUM-INTRACELLULARE*.

Johnson, John L*, Shiratsuchi, H*, Toba, H**, and Ellner, JJ*. *Case Western Reserve University, University Hospitals, and Cleveland VA, Cleveland, Ohio, USA, and **Osaka Prefectural Habikino Hospital, Osaka, Japan.

Mycobacterium avium-intracellulare (MAI) is the most frequent cause of late disseminated infection in patients (pts) with AIDS. Interactions of monocytes (MN) from AIDS pts with MAI have not been reported. We examined phagocytosis and inhibition of MAI growth in an *in vitro* model. MN from 11 AIDS pts [3 with disseminated MAI (AIDS-DMA)], and 13 healthy volunteers were precultured for 2 days and infected with 2 AIDS and 2 non-AIDS associated MAI strains. Uptake of MAI as detected by counting intracellular acid-fast bacilli was similar between AIDS pts, AIDS-DMA, and healthy controls. Intracellular growth of MAI was examined by a colony forming unit assay after 0, 4, and 7 days of culture. MN from AIDS pts were more effective in inhibiting intracellular growth of MAI at day 7 as compared to healthy donors for one of the AIDS-associated strains ($p<.05$). Intracellular growth was comparable for the remaining strains. Pretreatment of MN with IFN-gamma for 2 days before infection decreased MAI uptake in both the AIDS and healthy groups ($p<.05$ for each strain). Culturing infected MN with IFN-gamma 300 U/ml augmented MAI killing at 4 and 7 days by 30-50% for both AIDS pts and healthy donors ($p<.05$ for 3/4 strains tested). Healthy controls, AIDS-DMA, and AIDS pts showed comparable effects of INF-gamma. Since MN from AIDS pts exhibit normal interactions with MAI, disseminated disease can be attributed to an absence of modulating effects of CD4 lymphocytes. The demonstrated *in vitro* activity of IFN-gamma in culture with MN from AIDS pts provides a rationale for its use in immunoadjuvant therapy.

T.C.P.10

DEFINITION OF A SUBSET OF CD4$^+$ LYMPHOCYTES SELECTIVELY INFECTED WITH SIV/Mne USING THREE COLOR IMMUNOFLUORESCENCE AND PCR.

Clark, E.A.*; Gibbon, J.*§; Williford, D.§, Gale, M.*, Hoffman, P.§, and Gallatin, W.M.*§. *Regional Primate Research Center, University of Washington, Seattle, WA 98195, §Fred Hutchinson Cancer Center, Seattle, WA, U.S.A.

In previous work, we found that macaques infected with a simian immunodeficiency virus (SIV) isolated from Macaca nemestrina (SIV/Mne) have a selective depletion of CD4$^+$ T cells expressing high levels of the CD44 class of adhesion molecule (CD44^{hi}); in addition, we determined that productive infection of SIV could be activated in CD44^{hi} CD4$^+$ cells taken from infected animals, but not in CD44^{low} cells, and that the CD44^{hi} subset was differentially susceptible to SIV infection in vitro (Gallatin et al., PNAS, in press, 1989). However, these subsets differ in their response to the mitogens necessary to activate and detect virus in vitro. Therefore, we adapted PCR technology for directly identifying SIV in lymphocytes without the need for cell culture. We amplifed a 950 bp sequence in the gag region and found SIV sequences per se were restricted to the CD4$^+$ CD44^{hi} subset. Next, the target of SIV infection was more precisely defined using three color flow cytometry with fluorochrome-tagged mAb to CD45R and DNA dyes. In addition to finding SIV in CD4$^+$ cycling cells, we have also consistently detected viral sequences in CD4$^+$ CD44^{hi} CD45R$^-$ cells which are not in S/G2. The possibility that this latter subset, which has a memory T cell phenotype, is an important reservoir for latent infection, is being explored. In parallel, using PCR technology to detect viral DNA and RNA sequences, we are exploring the kinetics and host cell requirement for early SIV expression in CD4$^+$ subsets.
(Supported by NIH grants RR00166 and CA40272 and by a grant from the American Foundation for AIDS Research.)

T.C.P.11

PILOT STUDY OF ANTI-LEU3A IN HIV-1 SEROPOSITIVES

David Wilks, Walker LC, Habeshaw JA, Dalgleish AG
Clinical Research Centre, Harrow, U.K.

Objective: The CD4 antigen is a receptor for all isolates of HIV. Murine anti-idiotypic antibodies to anti-CD4 monoclonal antibodies inhibit the formation of syncytia in HIV-infected lymphocyte cultures. Anti-Leu3a(L3A) is an anti-CD4 antibody that blocks the binding of gp120 to CD4. This study is aimed to assess the safety of immunising HIV seropositive individuals with L3A, and to measure anti-idiotypic antibody responses.
Method: Four HIV+ volunteers (Walter-Reed stages 3 or 4) received 6 i.m. injections of 1 mg of L3A over a period of 10 weeks. They were monitored for 6 months post-treatment for acute toxicity, alteration of clinical status and routine haematological and biochemical parameters. Antibody responses to L3A were measured. T-cell immunophenotyping was performed before each injection and at monthly intervals during follow-up, and at 1 and 24 hours after injection in the first 3 patients.
Results: All patients have completed treatment and two have completed follow-up. There were no adverse reactions to injection or significant changes in routine laboratory parameters or total CD4+ lymphocyte counts. All patients made anti-Fc and anti-idiotypic antibodies to L3A, detectable at titres between 1/100 and 1/10,000. This was not associated with an increase in HIV neutralization titre, assessed by the syncytium inhibition assay.

T.C.P.12

INTERACTION OF HIV AND THE COMPLEMENT SYSTEM

Sölder,Brigitte*,Schulz,T.*,Hengster,P.*,
Löwer,J.***,Wachter,H.**,Dierich,M.P.*
*Inst.f.Hygiene,**L.-Boltzmann Inst.f.AIDS-Research,Innsbruck,
Austria,***Paul Ehrlich Inst.,Frankfurt,FRG

Objective: As several animal retroviruses have been shown to directly activate the complement system and to be lysed by human serum, we investigated the interaction between HIV and the complement system.
Methods and results: Purified HIV I was incubated with human serum and cleavage of the alpha chain of C3 and thus activation of the complement system was revealed using an immunoblotting technique. Recombinant envelope gp 160 was able to activate complement, too.In both cases activation required Ca and Mg indicating the predominant role of the classical pathway. HIV-infected cells were incubated in human serum and deposition of C3 was detected in an immunofluorescence assay and immunoblotting technique using an anti-human C3d antibody. In this case complement activation still occurred in the absence of Ca and thus via the alternative pathway.
Conclusion: These results show that HIV as well as HIV-infected cells activate the complement system via the classical and alternative pathway, respectively.

T.C.P.13 ANTIBODY-BINDING EPITOPES OF HIV-1 ENVELOPE GLYCOPROTEINS

Krowka, John*, Stites, D.P.*, Singh, B.** et al.
*University of California, San Francisco, USA,** University of Alberta, Edmonton, Canada.

Computer analysis and reports from the literature were used to select epitopes of HIV-1 envelope glycoproteins (ENVgp) as potential targets for recognition by antibodies. Sera from study subjects were analyzed by ELISA for antibodies that bound synthetic peptides which constitute these epitopes. Our results show that many ENVgp peptides react with low levels of antibodies in the sera of some HIV-infected individuals but only a very limited number of these sites are immunodominant. Two predicted immunodominant epitopes of HIV ENVgp, $ENVP_{466}$ (amino acids 466-481) and $ENVP_{497}$ (amino acids 497-509), were recognized by antibodies in the sera of most (>60%) HIV-infected individuals. The frequency of individuals with detectable serum antibodies to $ENVP_{466}$ or $ENVP_{497}$ did not differ among HIV-infected asymptomatic individuals and patients with AIDS or ARC. Purified antibodies to $ENVP_{497}$ had only very weak neutralizing activity against infectious HIV isolates. These results suggest that one dominant type of antibody response to HIV's gp120 has minimal protective effects. Antibody levels to one synthetic peptide epitope ($ENVP_{297}$) of HIV ENVgp (amino acids 297-308) were significantly higher ($p<0.002$) in patients with AIDS than in HIV-antibody positive (HIV Ab+) asymptomatic individuals, suggesting that antibodies to this epitope may be important in the pathogenesis of HIV infections. The identification and stimulation of immune responses to selected epitopes of HIV antigens using synthetic peptides may be useful in the design of vaccines to prevent or treat HIV infections.

T.C.P.14 MECHANISMS OF LYMPHOCYTE DYSFUNCTION IN HIV INFECTED PATIENTS

Vyakarnam Anna*, Matear P.*, Stanley B.*, Weller I.*, Beverley P.C.L. * Academic Department of Genito Urinary Medicine, * ICRF Human Tumour Immunology Group, University College & Middlesex School of Medicine, London W1. UNITED KINGDOM

It is clear from the literature that some HIV infected seropositives fail to respond to soluble antigens such as tuberculin and tetanus toxoid. T cell unresponsiveness to soluble antigens could arise from failure to trigger T cell functions such as proliferation and lymphokine release through the T3-Ti antigen receptor complex. To explore this possibility, we followed the response of peripheral derived mononuclear cells in three groups of patients - healthy seropositives, healthy seronegatives and ARC patients - to respond to anti T3 by proliferation and to secrete lymphokines such as tumour necrosis factor (TNF) α, β and gamma interferon (y-Ifn). The data shows that all patients respond to anti T3 as well as PHA and PMA in proliferation and lymphokine assays, suggesting that their T cells can be triggered through the T cell receptor complex. Interestingly cells from healthy seropositives and ARC patients made 3-10 times higher levels of TNF α and y-Ifn than healthy seronegatives upon activation with PHA + PMA or anti T3 suggesting that their cells may be activated in vivo. This data will be presented along with studies on proliferation to soluble antigens such as tuberculin and to gag p24, and with data on the effects of TNF α, β and y-Ifn on normal T cell function.

T.C.P.15 INHIBITION OF CD3 SIGNALLING BY gp120 IS ASSOCIATED WITH CD4 MODULATION AND ALTERED G PROTEIN-REGULATED CALCIUM GATING

W.W. Cruikshank, S.W. Pyle*, D.M. Center, and H. Kornfeld. Boston University School of Medicine, Boston, MA. *National Cancer Institute-Frederick Cancer Research Center, Frederick, MD.U.S.A.

Objective. To study the effects of gp120 on CD4 and CD3 expression, and on the signal transducing function of CD3.

Methods. Lymphocytes and Jurkat cells were incubated with 10^{-8} M gp120 for up to 48 hr. Periodically aliquots were analyzed for CD4 and CD3 expression with FITC-labelled anti-T4 and anti-T3 antibodies. At the same time points intracellular calcium (Ca) was quantitated with the fluorescent probe indo-1 AM following stimulation with anti-T3 antibody (1 ug/ml).

Results. Stimulation by anti-T3, or direct G_{α} activation by mastoparan resulted in Ca increase up to 530 nM. Gating of extracellular Ca accounts for 40% and 95% of the anti-T3 and mastoparan response respectively, determined by EDTA. Exposure to gp120 for up to 24 hr resulted in a progressive decrease in Ca response, of 50% and 90% compared to controls, for anti-T3 and mastoparan respectively. The Ca response returned to control levels by 48 hr. Surface expression of CD4, but not CD3, was decreased by incubation with gp120. Loss of CD4 from the cell surface peaked at 24 hr, with re-expression occuring by 48 hr.

Conclusions. Gp120 induces anti-T3 unresponsiveness and loss of CD4 in a similar time course. Effects on CD3 signalling appear to occur as a result of alteration in G protein signal transduction involved in Ca gating. The relationship between loss of CD4 and CD3 unresponsiveness has not been determined. These results may in part explain the mechanism for the observed defects in T cell antigen receptor signalling in HIV-1-infected cells.

T.C.P.16 IDENTIFICATION OF A POTENT SYNTHETIC HIV-1 IMMUNOGEN COMPRISING GAG-P24 TANDEM T- AND B-CELL EPITOPES

Chong, Pele; Sia, D.; Haynes, J.; Sydor, M. and Klein, M. Connaught Centre for Biotechnology Research, Connaught Laboratories Limited, Willowdale, Ontario, Canada.

Recent studies indicate that gag gene products may play a crucial role in the immune response against HIV infection: 1) as clinical progression to AIDS is associated with a reduction in the level of circulating antibodies to gag p24; 2) antibodies raised against p17 peptide is capable of inhibiting HIV-1 infection in vitro.

Using conventional structure prediction algorithms for T-cell and B-cell epitopes, we have identified and chemically synthesized several gag peptides vaccine candidates. In particular, an unconjugated HIV-1 p24 peptide (25-mer) containing both B- and T-cell epitopes in tandem was injected into mice in incomplete Freund's adjuvant and found to be capable of inducing a strong antibody response against p24 and its precursor p55 as judged by immunoblotting. In addition, the peptide presented in the appropriate MHC context was shown to be highly stimulatory for p24 specific murine T-cell clones.

T.C.P.17 HIV INFECTION OF BONE MARROW STROMAL MACROPHAGES

Hofman, Florence.*; Zheng, J.*; Rarrick, M.*; Gill, P.*; Mazumder, A.*.
*University of Southern California School of Medicine, Los Angeles, California, USA

A common clinical manifestation of Acquired Immune-deficiency Syndrome (AIDS) is pancytopenia, associated with a distinctive histopathology of the bone marrow (BM). These profound abnormalities in AIDS BM suggest an alteration in cellular composition or function of BM stromal cells. We have examined BM from five AIDS patients and determined that this BM population contains 1.0 to 8.9% HIV positive cells with anti-p24 antibody using the immunoperoxidase staining technique. BM cells from HIV positive and negative individuals were cultured for 7 days, during which time the nonadherent cells were removed leaving only the BM stromal population. The adherent stromal cells were composed of 30 to 40% macrophages and 10-20% fibroblasts as determined by the appropriate antibodies. Thirty to 40% of the stromal population were pleomorphic cells with abundant cytoplasmic processes, most likely dendritic cells. In stromal cultures of HIV positive individuals, p24 staining was associated with macrophages, in contrast to BM from HIV negative individuals which exhibited no staining. Furthermore, 95% of the stromal cells from HIV positive patients expressed Class II antigens, while only 40 to 50% of the HIV negative control BM cultures expressed this antigen. These data indicate that in AIDS BM, a subpopulation of macrophage stromal cells are HIV positive, and there is an increased expression of Class II antigens in this population.

T.C.P.18 A RAPID METHOD FOR DETECTION OF AMPLIFIED HIV DNA USING A HIGHLY SENSITIVE CHEMILUMINESCENT DNA PROBE SYSTEM (HPA)

Harper, Mary E.; McDonough, S.H.; Ryder, T.B.; Cabanas, D.K.; Chandler, S. and Kacian, D.L.
Gen-Probe, Inc., San Diego, CA, USA

Objective. To apply the Hybridization Protection Assay (HPA) to the detection of amplified HIV DNA.

Methods. HPA utilizes DNA probes directly labeled with acridinium ester and a simple homogeneous assay format with no separation steps. Hybridized probe is differentiated by a highly specific chemical hydrolysis reaction which selectively degrades acridinium ester label associated with unhybridized probe. Target sequences in the 10^{-16} to 10^{-17} mole range can be detected in <30 minutes. HIV-1 DNA was amplified by 30 cycles of standard PCR using gag-region primers described by Ou et al. (Science 239:295, 1988).

Results. Amplifications containing as few as 10-20 copies of input HIV-I DNA gave signals significantly above background, even when only 10% of the reactions were analyzed.

Conclusion. Since target amplification has become an important technique in determining the presence of HIV, a rapid and sensitive detection method is needed. Other techniques, including visualization after gel electrophoresis and hybridization in solution or to immobilized targets, require many steps and hours to days to complete. HPA offers important advantages in wide spread screening for HIV in studies involving epidemiology, diagnosis and treatment.

T.C.P.19

THE ROLE OF HIV-INDUCED IL 6 PRODUCTION IN B CELL ACTIVATION IN AIDS.

Elizabeth Crabb Breen[+], J.F. Salazar-Gonzalez*, T. Hirano**, T. Kishimoto**, & O. Martinez-Maza[+][+]. Depts. of [+]Micro./Immunol., and [+]Ob./Gyn., UCLA Sch. Med., Los Angeles, CA, USA, *Dept. Inmunol., Fac. Med., Univ. Aut. San Luis Potosi, SLP, Mexico, and **Inst. Molec. & Cell. Biol., Osaka Univ, Osaka, Japan.

B cells in HIV-infected persons are hyperactive, showing increased immunoglobulin (Ig) production and an increased percentage of B cells bearing activation markers. B cells are not infected by HIV, and the source of their activation is under debate. It is our experience that there is no direct binding to or activation of B cells by HIV, suggesting an indirect effect. IL 6, also known as B cell stimulatory factor-2 (BSF-2), is a terminal differentiation factor for B cells, and is produced by normal peripheral blood mononuclear cells (PBMNC) in response to HIV. Our studies of PBMNC from HIV-infected patients show a significant increase in spontaneous IL 6 production over normal individuals.

PBMNC from HIV-infected patients or healthy uninfected controls were isolated and placed into culture without stimulation. Culture supernatants (SN) were harvested at 24 or 48 hours, and 10 days. [IL 6] was determined in the 24/48 hour SN and plasma samples in a proliferative assay for IL 6 using the MH60.BSF2 cell line and/or an ELISA. 10 day [Ig] were determined by ELISA.

There is little or no detectable IL 6 in plasma from either group. In 24 hour SN, the mean [IL6] for normal individuals was 0.018 units/ml, whereas, in a group of HIV-infected patients, the mean [IL6] in 24 hour SN was 2.6 units/ml. The mean [IgG] of 10 day SN for the same two groups was 276 ng/ml and 836 ng/ml, respectively.

Preliminary studies on the mechanism of IL 6 induction have shown that high concentrations of purified recombinant gp 120 from HIV can induce IL 6 production by normal PBMNC, as does binding of anti-CD 4 antibodies.

The significant increase in IL 6 production by freshly isolated PBMNC from HIV + patients (who are also producing increased levels of Ig) suggests that overproduction of IL 6 *in vivo* in response to HIV may be contributing to the B cell activation seen in HIV-infected individuals.

T.C.P.21

MONOCYTES AND NEUTROPHILS FROM HIV-INFECTED INDIVIDUALS CONTAIN VERY LOW OR UNDETECTABLE LEVELS OF PROVIRUS AS DETERMINED BY PCR ANALYSIS.

Gregory T. Spear*; Moore, J. L.**; Landay, A.*; Kessler, H. A.*; Schochetman, G.** and Ou, C-Y.**.
*Rush Presbyterian St. Lukes Medical Center, Chicago, Illionis, USA. **Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To evaluate the relative levels of HIV provirus in lymphocytes (L), monocytes (M) and neutrophils (N) from HIV-infected individuals.
Methods. Blood cells from ten AIDS patients and 17 asymptomatic Ab+ HIV-infected individuals were isolated on Ficoll-Hypaque. N were isolated by lysis of RBCs from gradient bottoms. M were isolated by plastic adherence. L were plastic nonadherent cells. N and M were further enriched by treatment with anti T-cell monoclonals and complement. N and M contained less than 1% T cells. L contained less than 1% M or N. DNA was isolated and HIV-specific sequences in DNA equivalent to150,000 cells were amplified by the polymerase chain reaction. DNA was amplified with the SK-38/39 primer pair and detected by P32-labeled SK-19 probe. In some samples, radioactive product was quantitated.
Results. Provirus was detected in L from 26/27 individuals. However, provirus was not detectable in 11/20 M samples and 18/27 N samples. Densitometric quantitation of amplified products indicated that the levels of provirus were in all cases significantly higher in L than in M and N. Provirus in M and N was in some cases highest in individuals whose L samples were high in provirus content suggesting that some of the M and N signal could be due to contamination by L.
Conclusion. HIV infection of tissue macrophages in vivo has been shown by others. Our results indicate that HIV infection of peripheral blood M and N is infrequent. Thus, infection of M may occur after leaving the circulation.

T.C.P.23

A CROSS-REACTIVE CYTOTOXIC T CELL EPITOPE BETWEEN HIV-1 AND HIV-2

Nixon, Douglas*; Rizza, C.**; Gallwey, J.***; Rothbard, J.****; Howland, K.****; and McMichael, A.J..
*Inst. Mol. Med., John Radcliffe Hosp., Oxford, U.K., **Oxford Haemophilia Centre, Oxford, U.K., ***Harrison Dept., Radcliffe Infirmary, Oxford, U.K., ****ICRF, Lincoln's Inn Fields, London, U.K.

Objective. To test peptide analogues from HIV-2 and SIV sequences of the HIV-1 gag peptide epitope 265-279 (recognised by HIV specific CTL in association with HLA-B27).
Methods. An HIV-1 265-279 specific CTL line was tested for the ability to lyse HLA-B27 matched B lymphoblastoid target cells preincubated with or without peptide in a 4 hr ^{51}Cr release assay. Peptides were synthesized according to standard t-boc chemistry and peptide sequences were taken from the Los Alamos data bank.
Results. Results from a lysis assay are shown at a peptide conc. of 30µM.
Effector:Target ratio 30:1

Peptide	Sequence	%lysis
HIV-1 SF2	KRWIILGLNKIVRMY	69
HIV-1 Eli	KRWIIVGLNKIVRMY	60
HIV-2 ROD	RRWIQIGLQKCVRMY	56
SIVMM142	RRWIQLGLQKCVRMY	59
SIVK6w78	RRWIQLRLQKCVRMY	39
No peptide		15

Conclusion. The HIV-2 peptide is recognised by HIV-1 specific CTL.

T.C.P.20

CD8$^+$ T CELLS CAN SUPPRESS HIV REPLICATION VIA A SOLUBLE FACTOR

Brinchmann, Jan E.; Gaudernack, G; Thorsby, E; Vartdal, F.
The National Hospital, Oslo, Norway.

Objective. To examine the role of the cellular immune system in the control of HIV replication in the latent asymptomatic phase of HIV infection.
Methods. All cell subsets were isolated using positive immunomagnetic selection procedures. The cells were stimulated with Dynabeads coated with a monoclonal antibody (MAb) specific for the T cell receptor (TCR) and cultured in medium containing recombinant IL 2. The amount of HIV in cell supernatants was measured using a HIV p24 antigen capture ELISA.
Results. HIV was reproducibly isolated from all 38 consecutive cultures of CD4$^+$ T cells from 33 HIV seropositive individuals. Addition of activated CD8$^+$ T cells inhibited the HIV replication in a dose dependant manner. This inhibitory activity could not be blocked by MAbs specific for HLA class I, CD8 or LFA 1, was exerted across semipermeable membranes and was found in the cell-free supernatants of CD8$^+$ T cells. Both allogeneic and autologous CD8$^+$ T cells showed inhibitory activity.
Conclusions. CD8$^+$ T cells can inhibit HIV replication in naturally infected CD4$^+$ T cells at low multiplicities of infection. This inhibitory activity seems to be mediated by a soluble factor.

T.C.P.22

PRESENCE OF ANTI-HIV ANTIBODIES IN GENITAL SECRETIONS

P.M.V.Martin, L.Bélec, G.Steenman, M.C.Georges-Courbot, A.J.Georges.
Pasteur Institute, Bangui, Central African Republic

Objective : To study the presence and the role of the local immune response to HIV in genital secretions from heterosexual individuals exposed to, or infected by, HIV.
Methods : Sera and genital secretions from 75 women and 15 men were tested by Western blot against HIV1 antigens, for the presence of IgG and IgA antibodies. The 75 women were healthy seropositive (15), healthy seronegative wives of HIV seropositive men (15), AIDS patients (15) and controls (30). Men were healthy seropositives (8), ARC (2) or AIDS (1) patients, and controls (4). Neutralisation power of genital secretion was studied by neutralisation of a competitive assay between HIV and anti-CD4 monoclonal antibodies to T4 lymphocytes.
Resluts : The semen of all seropositives had IgG antibodies to GP160 of HIV1, and 8/11 seropositives possessed IgA to GP160. Both IgG and IgA isotypes directed against all viral antigens, including GP, were present in vaginal secretions (VS) of all healthy seropositive and AIDS women. IgG and IgA were not detected in VS from women of other groups. The presence of IgA in VS established that HIV elicits a local immune response after heterosexual infection. The putative role of local antibodies in the attachement of the virus to the CD4 receptor has been studied.
Conclusion : Immune mediation by secretory IgA has proven to be efficient for certain viral diseases and could play a role in the heterosexual transmission of HIV.

T.C.P.24

ANTIBODIES WHICH RECOGNIZE BOTH CONSERVED AND VARIABLE REGIONS OF HIV-1 GP-120 ARE RESPONSIBLE FOR HIV-SPECIFIC ADCC.

Koup, Richard*, Pikora, C.*, McKenzie, S.**, Mazzara, G.**, Panicali, D.**, and Sullivan, J.*. *University of Massachusetts Medical School, Worcester, and **Applied bioTechnology, Inc., Cambridge, Massachusetts, USA.

Objective: To define epitopes within the envelope glycoprotein complex gp120/gp41 of HIV-1 which are recognized by antibodies which mediate ADCC.
Methods: Multiple sera from recent seroconverters, which demonstrated type-specific neutralization against HIV isolates IIIB and RF, were tested for their ability to mediate ADCC against a B-cell line infected with recombinant vaccinia vectors expressing the envelope genes of IIIB or RF. Vaccinia vectors which expressed specific deletions within gp-120 were also used in these assays. In addition, human and mouse monoclonal antibodies to defined epitopes of gp-120 were used to map specific ADCC epitopes within the gp-120 molecule.
Results: All human sera tested to date, even those displaying a type-specific neutralizing response, demonstrated a group-specific ADCC response to IIIB and RF envelope glycoproteins indicating that conserved regions of HIV-1 envelope glycoproteins are recognized by ADCC antibodies. HIV-1-positive sera were able to mediate ADCC against cells infected with a truncated deletion vector which did not express the first, second and third variable regions of gp-120. Using monoclonal antibodies we have mapped ADCC epitopes within the conserved and the variable regions of HIV-1 gp-120.
Conclusion: Epitopes within variable and conserved regions of HIV-1 gp-120 are recognized by ADCC antibodies.

T.C.P.25

CD8+HMK1+ CELLS SUPPRESS THE HIV-SPECIFIC T CELL ACTIVITIES.

JOLY P*, GUILLON J-M*, AUTRAN B*, PLATA F°, MAYAUD C+, DEBRE P* et al. *Lab. Immuno. Hôp. Pitié-Salpétrière, Paris; °Lab. Imm. Bio. Mol. Retrovirus, I. Pasteur, Paris: +Dpt. Pneumo., Hôp. Tenon, Paris.

OBJECTIVE : We have demonstrated HIV-specific cytotoxic T lymphocytes in lungs and their progressive disappearance during the course of HIV infection. The aim of this study was to detect factors or cells wich could down-regulate the anti-HIV T cell responses.

METHODS : Alveolar lymphocytes were recovered from 41 patients at various stages of the HIV disease. Their cell surface phenotype was determined and their cytolutic function was tested against 51Cr-labelled autologous alveolar macrophages and cell lines expressing HIV proteins; both standard chromium release assay and limiting dilution analysis (LDA) were performed. Various cell subsets were tested for their putative suppressor function onto HIV-specific cytolysis.

RESULTATS : In patients with advanced HIV disease, in whom no signifiant CTL acitivity could be demonstrated in bulk assayz, effector CTL specific for HIV could still be detectable by LDA. The biphasic LDA plots suggested the presence of suppressor cells IF analysis of alveolar lymphocytes revealed a progressive increase of CD8+HMK1+ cells that mirrored the regression of anti-HIV CTL activity. Selection experiments and IF cell sorting demonstrate that alveolar CD8+HMK1+ lymphocytes suppress the effector phase of anti-HIV CD8+HMK1+ lymphocytes suppressed the effector phase of anti-HIV as well as anti-HLA CTL lysis and were not HLA-restricted. The CD8+HMK1+ cells did not kill K562 cells not the HIV-specific effector CTL.

CONCLUSION : Suppressor T cells could thus explain the inefficiency of host cellular immune defenses against HIV.

T.C.P.26

AN HLA-DR+, LIGHT DENSITY, PERIPHERAL BLOOD MONONUCLEAR CELL PRODUCES ALPHA INTERFERON IN RESPONSE TO HIV

Rinaldo, Charles; Toso, J.; Rappocciolo, G.; Gupta, P. and Ferbas, J.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To characterize alpha interferon (aIFN) production induced by HIV in cultures of peripheral blood mononuclear cells (PBMC).

Methods. PBMC from healthy HIV seronegative donors were enriched for different subpopulations and incubated for 16 hr at 37C with HIV-infected U937 ($U937_{HIV}$) promonocytic cells. Supernatants were assayed for aIFN by antiviral activity in human WISH cells, by neutralization with antiserum to aIFN, and by stability after treatment at low pH.

Results. Percoll gradient density and flow cytometric analyses showed that light density, HLA-DR$^+$ PBMC were responsible for production of acid-stable aIFN in response to $U937_{HIV}$ cells. Enrichment of subpopulations by depletion with monoclonal antibodies and complement indicated that these aIFN-producing cells were non-T (CD3$^-$), non-natural killer (NK) (CD16$^-$) and non-B (CD20$^-$) lymphocytes. The aIFN-producing cells were also predominantly not plastic adherent (monocytic), and did not express Leu 19 (NK cell marker).

Conclusion. PBMC which produce acid-stable aIFN in response to HIV-infected promonocytic cells are light density and HLA-DR$^+$, and are not present within the predominant populations of T, NK, B and monocytic cells. Similar subpopulations of light density, HLA-DR$^+$ PBMC have been associated with augmented lysis of virus-infected targets by NK cells, and could be related to enhanced NK cell lysis of HIV-infected promonocytic cells (Rappocciolo, et al., J. Clin. Micro. 27:41, 1989).

T.C.P.27

ANTIGEN-REACTIVE T LYMPHOCYTES ARE PRESENT IN HIV-INFECTED INDIVIDUALS WHO ARE NON-REACTIVE IN CONVENTIONAL LYMPHOCYTE PROLIFERATIVE ASSAYS.

Sabbaj, Stefanie; Adams, P, Orosz, C., Para, M., Fass, R., and Whitacre, C.; The Ohio State University AIDS Clinical Trials Group, Columbus, Ohio USA

Objective. The lymphocyte proliferative response to soluble antigens such as tetanus toxoid has been reported to be absent after HIV infection. We examined the response to tetanus in HIV-infected individuals using conventional lymphocyte proliferative assays in comparison with limiting dilution analysis (LDA), where a frequency of tetanus toxoid specific T cells can be determined.

Methods. Bulk proliferative responses of peripheral blood mononuclear cells (PBMC) from ARC, asymptomatic and seronegative controls were assessed by the uptake of ^{3}-H thymidine after 120 hours of culture with tetanus toxoid. For the LDA, PBMC were serially diluted and cultured with tetanus toxoid and irradiated autologous monocytes for 20 hours. Antigen-reactive cells were detected by the production of IL-2 using the IL-2 dependent cell line, CTLL-20. LDA frequencies were calculated using chi square minimization.

Results. Lymphocyte proliferative responses to tetanus were detected in all control subjects, 5 of the 6 asymptomatic persons, but none of the ARC patients tested. By LDA, control individuals showed 1/9576 - 1/16,099 (62-104 per 10^6) tetanus-reactive lymphocytes, asymptomatic persons showed 1/2663 - 1/31,730 (32-442 per 10^6), and ARC patients showed 1/16,187 - 1/17,046 (59-62 per 10^6) lymphocytes. Therefore, discrepancies between proliferative and LDA responses were particularly obvious in the ARC subgroup of patients.

Conclusions. Tetanus-specific lymphokine secreting cells can be detected in HIV infected individuals by LDA even when conventional bulk proliferative responses to tetanus are absent. These results raise important questions about the interpretation of data from lymphocyte bulk proliferative assays regarding the presence or absence of immune responses. (Supported by NIH grant AIDSP, NIAID AI25924)

T.C.P.28

THE IMMUNOREGULATION OF HUMAN IMMUNODEFICIENCY VIRUS IN HUMAN SEMEN

Rhoads, Joanne*; Polonis, V.*; Husayni, H.*; Birx, D.*; Hendricks, R.*; Burke, D.*; Redfield, R.*. * Walter Reed Retrovirus Research Group, Washington, D.C. U.S.A.

Objective: To characterise the humoral immune response to HIV viral specific proteins and epitopes in the male genital tract.

Methods: Ten male HIV seropositive subjects were evaluated to characterize the immune response against HIV viral proteins and epitopes in the seminal plasma as compared with matched sera. In vivo viral antigen load in the two compartments was evaluated by isolation of HIV from semen and peripheral blood, and by measurement of free p24 in seminal plasma and sera.

Results: Antibody production against viral envelope proteins are comparable in seminal plasma and sera; however, there is a marked decrease in reactivity against specific HIV structural proteins in the seminal compartment. The presence of antibodies against unique envelope epitopes is currently being evaluated. Eight of ten HIV (+) subjects had positive peripheral blood cultures for HIV; of these eight subjects, only two had positive semen cultures for HIV.

Conclusion: These differences may reflect either poor antibody production or differential viral protein expression in the male reproductive tract. This data supports the concept that the male reproductive tract is a privileged immunologic site.

T.C.P.29

RELATIONSHIP BETWEEN ANTIBODY AGAINST THE C-TERMINAL REGION OF GP120 AND MARKERS OF HIV SPECIFIC IMMUNOREGULATION.

Polonis, Victoria*; Husayni, H.,* Lee, T.**; Essex, M.**; Burke, D.S.*; Redfield, R.R.*, *Walter Reed Retroviral Research Group and ** Harvard University, Boston, MA. U.S.A.

Objective. Characterization of the humoral immune response to the HIV-1 envelop antigens and correlation to stage of infection and ability to isolate HIV-1 from PBMC. Methods. Serum anti-envelop antibodies from 126 clinically staged patients were characterised with protein dot blot and Western blot techniques. Antibodies against gp160, gp120 and the specific epitope of gp120 (448C) were studied.

Results. A correlation was found between the presence of specific antibody (α-448C), clinical stage and inability to isolate virus. This correlation was not found with antibody titers to gp160 and gp120. Antibody to 448C was detectable in 70% (46/66) of Walter Reed Stage (WRS) 1-2, as compared to 33% (11/33) WRS 5-6. Antibody to 448C was detectable in 73% of viral isolation negative and 41% of viral isolation positive patient sera. Of sera from WRS 1-2 patients, 77% (36/47) virus isolation negative and 52% (10/19) virus isolation positive demonstrated α-448C. Of the sera from WRS 5-6 patients, 26% (7/27) virus isolation positive and 67% (4/6) virus isolation negative demonstrated α-448C.

Conclusion. These data demonstrate that 448C contains an epitope(s) which correlates with early disease and inability to isolate virus from PBMC, demonstrating a relationship between α-448C and parameters of effective viral immune regulation.

T.C.P.30

CYTOKINES ALTER SUSCEPTIBILITY OF HUMAN MONOCYTES TO INFECTION BY HIV-1

Skillman, Donald R., Gendelman, H.*, Meltzer, M.**, and the Walter Reed Retrovirus Research Group, Walter Reed Army Medical Center, *H.M. Jackson Foundation, **Walter Reed ARmy Institute of Research, Washington, D.C., United States of America

Objective. Evaluate effects of cytokine pretreatment on the interaction of HIV with blood-derived monocytes in vitro.

Method. Monocytes from HIV-seronegative donors were isolated by centrifugal elutriation and cultured in medium with recombinant human colony stimulating factor-1 (MCSF, Cetus Corp., Emeryville CA). After 7 days, any of several recombinant human cytokines (interleukins 1,2,3, and 4; tumor necrosis factor a: GM-CSF; interferons a,B, and y) were added at 5 to 500 units/ml for 24 hours to MCSF-treated monocytes. All cultures were washed. HIV ADA, a monocytotropic HIV-1 strain, was added to pretreated and control monocytes. Culture fluids were monitored for viral p24.

Results. Viral p24 antigen was detected 2 weeks after HIV infection in all MCSF-treated control monocytes cultured without additional cytokiine pretreatment. Most cytokines had little or no effect on p24 release over this time interval. In contrast, levels of p24 antigen in culture fluids were significantly reduced by 5 to 500 units/ml GMCSF.

Conclusions. Pretreatment of human monocytes with any of several different cytokines alters infectivity of HIV for monocytes. Such in vitro testing of immunomodulators may prove beneficial in the selection of therapeutic regimens for infected individuals.

T.C.P.31

FUNCTION OF CD8 CELL SUBSETS IN HIV INFECTION

Plaeger-Marshall,Susan; Haussner,M.A., Gudeman,V., Smith,D, and Giorgi,J.V.
UCLA School of Medicine, Los Angeles, CA, USA

Objective. We previously have identified specific subsets of CD8 cells that increase in individuals with HIV infection. The present study was designed to characterize the function of CD8 subsets to determine their role in the immune response to HIV.
Methods. Subjects were 20-30 HIV seropositive (HM$^+$) or seronegative (HM$^-$) male homosexuals participating in the Los Angeles Multicenter AIDS Cohort Study, or healthy heterosexuals (HT). Monoclonal antibodies were directed against Leu7(HNK-1), and OKT10(CD38). Complement lysis was used to deplete cell subsets. Cytotoxic function was assessed by lectin-dependent cellular cytotoxicity (LDCC) employing Concanavalin A and ^{51}Cr-labelled CEM target cells in a 4 hour assay.
Results. Initial experiments showed that HM$^+$ had elevated levels of LDCC (34±12% lysis) compared to HM$^-$ (24±11) or HT (20±9) controls. LDCC in HM$^-$ correlated with levels of CD8 cells bearing Leu7, whereas LDCC in HM$^+$ correlated with levels of CD8 OKT10$^+$ cells. Cell depletion experiments to more directly assess the role of CD8 subsets in LDCC confirmed that CD8 cells mediate LDCC in HM$^-$ and HM$^+$ (80-90% inhibition). Depletion of Leu7 removed > 50% of the lytic activity in HM$^-$ and an average of 35% in HM$^+$. Depletion of OKT10$^+$ CD8 cells had no effect on LDCC of HM$^-$; preliminary experiments in HM$^+$ have been variable.
Conclusion. Our data indicate that, as has been shown previously in healthy control subjects, LDCC in HM$^-$ appears to be mediated predominantly by CD8 Leu7$^+$ cells. However, despite the increased levels of CD8 Leu7$^+$ cells, this CD8 cell subset does not appear to be the major contributor to the elevated LDCC in HM$^+$.

T.C.P.32

ANTI-HIV ANTIBODY DIRECTED CYTOTOXICITY: CELLULAR AND HUMORAL DEFECTS

Tyler, Douglas; Stanley, D.; Nastala, C.; Stine, K.; Bolognesi, D. and Weinhold, K., Duke University Medical Center, Durham, NC, USA

Objective: To define specific defects altering the efficacy of anti-HIV-1 antibody directed cytotolysis.
Methods: The ability of freshly isolated antibody armed NK/K cells from HIV-1 infected individuals to lyse virally infected targets declines rapidly as disease progresses. To determine whether humoral factors contribute to this decline, patient(pt) sera was tested for its ability to confer cytolytic activity on normal NK/K cells, either by its direct addition to 6 hr ^{51}Cr release assays or by its pre-incubation with donor lymphocytes for two hours prior to testing. To determine the possible role of cellular defects, pt cells were tested for cytolytic activity both in the presence of and again after pre-incubation with a high titered anti-HIV-1 serum known to mediate high levels of antibody dependent cytolysis. Less than 5% lytic activity was considered indicative of a defect.
Results: Half of 80 asymptomatic patients tested showed specific humoral and/or cellular defects in anti-HIV-1 antibody directed cytotoxicity. The absence of antibodies capable of directing anti-HIV-1 specific cytolysis, occuring in 20% of pts, was the most common humoral defect identified. A second humoral defect was found in 10% of pts who had high levels of these antibodies, but were unable to arm normal NK/K cells to become cytotoxic for infected targets due to the presence of inhibitory factors in their serum. Cellular defects, identified by the inability of pt lymphocytes to mediate cytolysis even with the high titered serum, were found in 10% of the cohort. This defect was apparent in an additional 10% of pts, who showed signs of humoral defects as well. All 20 AIDS pts tested showed either a humoral or cellular defect, with 60% having a severe combined dysfunction.
Conclusion: Using multiple assays, HIV-1 infection was found to cause severe defects in antibody dependent cytolytic reactivity. The magnitude and frequency of these defects increases with disease progression and may significantly alter the effectiveness of antibody directed cytotoxicity in vivo. Through the recognition of these defects, specific restorative therapies can be better designed.

T.C.P.33

CHARACTERIZATION OF p17 PROTEIN ON PLASMA MEMBRANE OF HIV-INFECTED CELLS BY MONOCLONAL ANTIBODIES AND EPITOPE MAPPING

Ruscetti, Frank*; Mikovits, J.**; Baseler, M.** Sheu, M.*** and Papsidero, L.***. *Lab. Molec. Immunoreg., BRMP, NCI-FCRF and ** BCDP and CIS, PRI, NCI-FCRF, Frederick, MD, ***Cellular Products Inc., Buffalo, NY., U.S.A.

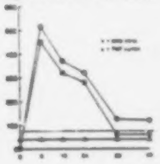
Objective. To identify and characterize HIV-1 p17 protein on cell surface of HIV-infected cells.
Methods. Standard viral, monoclonal antibody and FACS techniques were used. Epitope mapping was done using overlapping hexapeptides spanning p17.
Results. Previous data suggested that neutralizing antibodies to the p17 core protein could be found in AIDS patients and that anti-p17 antibodies could neutralize HIV-infectivity in vitro. To determine the sites within p17 reponsible for this, twelve monoclonal antibodies to p17 were made. HIV-1 infected THP-1 a human monocytoid leukemic cell line, and Hut-78, a neoplastic T-cell line, were analysed by FACS for p17 binding. Four of 12 anti-p17 antibodies reacted with the cell surface of HIV-infected cells. Two anti-p17 antibodies (p17A and p17B) which inhibited viral infectivity in vitro, also reacted with the cell surface of HIV-infected cells. Epitope mapping showed that p17B recognized a peptide of amino acids 17-22 and p17A recognized two peptides from 12-19 and 100-105 in the p17 sequence. A soluble synthetic peptide from amino acids 12-22 blocked virus neutralization and binding of p17 on the cell surface by p17A while peptides containing amino acids 100-105 did not block cell surface binding.
Conclusions. The myristilated N-terminal gag protein p17 was identified on the cell surface of HIV-infected cells. Using specific p17 monoclonal antibodies, epitopes on the p17 molecule necessary for virus neutralization and recognition of cell surface bound p17 were determined.

T.C.P.34

HIV-1 STIMULATES TUMOR NECROSIS FACTOR-ALPHA RELEASE FROM HUMAN MONOCYTE/MACROPHAGES (MØ).

Daar, Eric S.; Chia, J.K.S.; Yim, D.; Ho, D.D.
UCLA School of Medicine and Cedars-Sinai Medical Center
Los Angeles, California U.S.A.

Objective: To determine if HIV-1 will stimulate the release of tumor necrosis factor-alpha (TNF) from human MØ in vitro.
Methods: HIV-1 (□) and mock (△) preparations were made by ultracentrifugation. Endotoxin in these preparations was excluded by the limulus lysate assay and by a bioassay using a mouse macrophage cell line. TNF was measured using the L-929 bioassay, and specificity was confirmed by neutralization with TNF-alpha-specific monoclonal antibody.
Results: The inoculation of normal blood MØ in vitro with endotoxin-free HIV-1 results in a burst of TNF (Fig.) in a dose-dependent manner. TNF release precedes expression of HIV-1 replication in MØ and is also observed with heat-inactivated HIV-1. The TNF induction by HIV-1 is not neutralized by addition of polymyxin B (○) and not mediated by allogeneic stimulation. Preliminary results show that purified gp120 does not induce TNF and recombinant soluble CD4 does not block TNF induction by HIV-1.
Conclusion: A component of HIV-1 can induce transient TNF release from normal blood MØ in vitro.



T.C.P.35

Comparative study of NK and ADCC activity of CD3-, CD2+,CD16+ cell lines obtained from normal seronegative and HIV seropositive subjects.

- Daniel Scott, Françoise Vuillier and Guillaume Dighiero
- Unité d'Immunopathologie et Immunohématologie de l'Institut Pasteur 75724 PARIS Cédex 15 -FRANCE

Highly purified CD3-, CD16+ cell lines were obtained from 5 normal seronegative subjects, 5 asymptomatic HIV seropositive carriers and 5 AIDS patients.
Purification procedure consisted of negative immunoselection by panning technique with anti-CD3 and anti-CD4 monoclonal antibodies and positive selection on a cell sorter (EPICS 752) by labelling CD3, CD4 depleted populations (< 1% CD3+, CD4+) with anti-CD16 PE (Leu 11c phycoerythrin). From 99 to 100 purified CD3-, CD16+ were cultured in 96-well in MEM medium with r-IL2, in the presence of irradiated allogenic peripheral blood lymphocytes and irradiated EBV transformed B cell line (LAZ 388). After 60 days culture, cell lines were assessed for their NK activity against K 562. ADCC activity against P815 cell line previously incubated with anti-P815 antibodies and liberation of cytotoxic factors by preincubation with U-937 cell line. Preliminary results suggest that NK and ADCC activity as well as liberation of cytotoxic factors are depressed in NK cell lines obtained from HIV seropositive patients.

T.C.P.36

ROLE OF FC RECEPTORS IN THE BINDING OF HIV TO MONOCYTES

Melendez-Guerrero, Loyda*, Nicholson, J.K.A.**, McDougal, J.S.**, and Dawson, C.D.**.
*Emory University, Department of Pathology, Atlanta, Georgia, U.S.A.,
**Centers for Disease Control, Atlanta, Georgia, U.S.A.

Objective. Monocytes can be infected with HIV, however, the mechanism of the infection is unknown. Since CD4 is weakly expressed on monocytes, we explored the possibility that Fc receptors (FcR) may play a role in the binding of HIV-1 to monocytes.
Methods. Two-day adherent monocytes were removed from gelatin-coated flasks and incubated with concentrated HIV. Fluorescein (FITC)-anti-HIV and phycoerythrin (PE)-anti-CD14 were then added. For binding inhibition studies, monocytes were preincubated with anti-FcR monoclonal antibodies (Mabs) or anti-CD3 Mabs (which bind monocyte FcR). The samples were analyzed by flow cytometry, gating only on the CD14$^+$ cells.
Results. Neither anti-FcR Mab nor anti-CD3 Mabs inhibited virus binding. When the promonocyte cell line, U937, was tested, similar results were found.
Conclusion. These studies indicate that HIV does not bind to the monocyte FcR.

T.C.P.37

IDENTIFICATION OF COMMON EPITOPES OF HIV 1 AND HIV 2 BY MONOCLONAL ANTIBODIES

Zorr, Bernd and Habermehl, K.-O.
Institute for Clinical and Experimental Virology, Free University of Berlin, Hindenburgdamm 27, 1000 Berlin 45, FRG

26 monoclonal antibodies were prepared, directed against our HIV 2-isolate with intertypic characteristics (HIV-MDS) and tested against HIV-2 (NIHZ), HIV-2 (ROD), HIV-1 (HTLV 3B) and HIV-MDS. The tests were performed with ELISAs, RIPA, and Western Blots prepared by sucrosegradient-purified antigens as well as by recombinant envelope protein from HIV-1 (aa 350 - aa 750, DuPont). 8 of the monoclonal antibodies directed against the envelope reacted groupspecific with all virus antigens. A second group of 8 monoclonals directed against gag-pol reacted also with all virus antigens. A third group of 10 monoclonals directed against structural and non-structural virus proteins reacted typespecific just with the HIV-2 isolates. The significance of the identified epitopes for the neutralization of the virus strains has been determined.

T.C.P.38

EFFECT OF HIV ON ANTIGEN-INDUCED T CELL PROLIFERATION

Küpcü, Zaruhi*; Barrett, N.*; Dorner, F.*; Gallo, R.C.***; Eibl, M.M.**, Mannhalter, J.W.**
*IMMUNO AG, Orth/D., Austria; **Inst. of Immunology, Univ. of Vienna, Austria; ***N.C.I., N.I.H., Bethesda, USA.

Objective. Examination of antigen-induced T cell proliferation in response to a particulate bacterial antigen (E.coli) and tetanus toxoid following infection of the cells by HIV.
Methods. In one set of experiments, monocytes (Mo) were pulsed with antigens prior to co-cultivation with autologous T cells and HIV (1x10E5-1x10E1 IU/ml). In the second set of experiments, both HIV and antigens were added to the cultures upon initiation of the incubation period. Antigen-induced T cell proliferation was measured by ^{3}H-thymidine incorporation after 7 days of incubation.
Results. A difference was found using either pre-pulsed or non-pulsed Mo concerning the antigen-induced T cell proliferative response in the presence of infectious HIV. HIV caused a dose-dependent suppression of antigen-induced T cell proliferation in the presence of the pre-pulsed Mo, e.g. T cell proliferation in response to tetanus toxoid-pulsed Mo decreased from 24.1 ± 2.8 dpm ± s.d. x 10E-3(in the absence of HIV) to 0.8 ± 0.1 dpm ± s.d. x 10E-3 (in the presence of HIV, 1x10E5 IU/ml). The simultaneous addition of antigen and infectious HIV to the Mo in the second set of experiments led to an increase of T cell proliferation, e.g. in response to tetanus toxoid, T cell proliferation increased from 25.0 ± 1.2 dpm ± s.d. x 10E-3 (in the absence of HIV) to 68.6 ± 5.7 dpm ± s.d. x 10E-3 (in the presence of HIV, 1x10E5 IU/ml). Similar data were observed with E.coli.
Conclusion. Addition of infectious HIV to co-cultures of T cells and antigen-pulsed Mo results in a decrease of antigen-specific T cell proliferation. Conversely, the simultaneous presence of T cells, Mo, antigens and HIV in the cultures leads to an increase of the antigen-induced T cell response.

T.C.P.39

HIV INDUCED, HIV SPECIFIC IN VITRO ANTIBODY RESPONSE.

Jean-François Delfraissy, C. Wallon, F. Boué, J. Dormont, P. Galanaud, F. Barré-Sinoussi.
INSERM, U 131, Clamart. Institut Pasteur, Paris, France.

Objective : To induce specific B cell response to HIV protein or env gp160 protein.
Methods : Purified B were cultured in vitro in the presence of purified T cells or IL2, with different preparations of HIV unfractionnated protein preparation. The specific HIV response were measured by Elisa and Western Blot.
Results : No response was observed in negative donnor. In HIV positive, HIV induced a specific antibody response. Anti HIV ab were only obtained when T cell help was provided by interleukine 2 and interferon alpha but not in the physical presence of T cells. Anti HIV ab produced in cultures were predominantly directed against gp160 and or gp110. In vitro antibody production was inhibited by cycloheximide, anti env 3, mab, but inconstantly by anti CD4. The antibody response required the presence of autologous monocytes which can be replaced by interleukine 6. Allogenic monocytes are not functionnal. Identical results were observed with gp160 peptides.
Conclusion : HIV specific in vitro antibody response directed the env proteins can be induced in HIV+ patients, but not in HIV- controls.

T.C.P.40

TUMOR NECROSIS FACTOR INHIBITS ACTIVATION OF B CELLS BY HUMAN IMMUNODEFICIENCY VIRUS (HIV).

Jean-François Delfraissy, C. Wallon, F. Boué, P. Galanaud and F. Barré-Sinoussi. INSERM, U 131, Clamart. Institut Pasteur,Paris, France.

Objective : In vitro HIV induced B cell proliferation. However the precise interactions between HIV and first steps of B cell activation and with B lymphokines are poorly understood.
Methods : We have investigated the effects of recombinant human tumor necrosis factor alpha (TNF alpha) on human B cell proliferation. Human B cells were activated by anti-mu ab, B lymphokines (12 Kd BCGF, IL2), Pokeweed mitogen (PWM) or HIV unfractionated protein preparation.
Results : TNF-alpha acts as a B cell growth factor on anti-mu activated B cells. TNF-alpha does not modify the B cell proliferation induced by anti-mu ab and lymphokines or PWM.
HIV preparation supports a moderate B cell proliferation enhanced by the 12 Kd BCGF or IL2. TNF alpha inhibits in a dose dependant manner the HIV induced proliferation. This effect is not due to a cytotoxic activity and is observed in the absence of monocytes. Interferon alpha and gamma have no inhibitory effect in the same culture conditions.
Conclusion : We conclude that TNF alpha can selectively modulate the B cell activation induced by HIV in vitro.

T.C.P.41

FcR expression in HIV-1 infected T cell Lines

C. Carini,M. Chierchi,F. Aiuti,Dept. Allergology & Clinical Immunology,Univ.of Rome "La Sapienza",Rome,Italy.

It is well known that EBV transformed B lymphoblastoid cell lines,such as RP MI 8866,express a large number of FcεR on their surface. It has been recently reported that mRNA encoding the FcεR was not detected in normal human T cells or T cell lines except HTLV-I transformed T cell line. These findings suggested to us the possibility that infection of T cells with another retroviruses HIV-1 might induce the expression of FcεR on T cells or formation of IgEbFs. We then tryied to analyse the presence of FcεR on 3 HIV infected T cell lines by cytofluorometry by using double staining with anti-CD4 or anti-CD8 and an an anti-FcεR monoclonal antibody. To detect the presence of IgEbF in the culture supernatant of these HIV infected T cell lines a rosette inhibition assay was used. Preliminary results of the HIV infected T cell lines studied indicate that only one showed a clear expression of FcεR at 3 days of culture as analysed by cytofluorometry. In contrast the presence of IGEbF was seen in 2 of the 3 lines examined. These preliminary results indicate that infection of T cells with HIV-1 could induce the expression of FcεR on T cell lines and the formation of IgE BF in the culture supernatants of the cell lines studied.

T.C.P.42

PREVALENCE OF ANTI-nef POSITIVE SERA IN HIV-INFECTED PATIENTS : MAPPING OF THE MAJOR EPITOPES OF nef PROTEIN USING SYNTHETIC PEPTIDES.

BAHRAOUI Elmostafa * ; VAN RIETSCHOTEN, J.** ; GRANIER, C.** ; GLUCKMAN, J-C. *** ; MONTAGNIER, L.* SABATIER J-M. **

* INSTITUT PASTEUR PARIS
** CNRS UA 1179 MARSEILLE
*** CERVI PARIS, FRANCE

Objective : to study the prevalence of anti nef positive sera in HIV- infected patients and to map the immunodominant epitopes using synthetic peptides.

Methods : Human sera were tested for the presence of anti-nef antibodies by RIA with recombinant ^{125}I-nef expressed in E.coli and by ELISA using synthetic peptides.

Results : Among the HIV positive sera tested by RIA 70 ± 6,5 % were found anti-nef positive. Anti-nef antibodies bound to nef with high affinity (K 0.5. = 2.2 10^{-9} M). Anti-nef positive sera were assayed on a set of synthetic peptides (ranging from 11 to 66 a.a. and spanning the total sequence of nef from HIV-1), wich showed a significant diversity of the immunodominant antigenic sites. A strong immunoreactivity was observed with either N-terminal or C-terminal regions meaning a heterogeneity of the humoral responses against nef.

Conclusion : these results provide a means for an early diagnosis of HIV infection based on the detection of anti nef antibodies using synthetic peptides.

T.C.P.43

INCREASED SERUM LEVELS OF SOLUBLE IL-2 RECEPTORS (sIL-2R) IN HIV INFECTION. CORRELATION STUDIES AND CLINICAL SIGNIFICANCE

Lang, Jean-Marie; Coumaros, G.; Levy, S. ; Aleksijevic, A.; Lehr, L. and Koehl, C.
Université Louis Pasteur, Strasbourg, France.

Objective. To gain further insights into the cell origin(s) and clinical significance of elevated sIL-2R in HIV infection.
Methods. sIL-2R were measured using a sandwich enzyme immunoassay in 105 consecutive HIV-infected subjects. Data were further correlated with biological markers of disease activity. Follow up studies were performed every 4 months in untreated and AZT-treated individuals. To assess whether elevated sIL-2R may contribute to the immune defect sIL-2R were generated in vitro and supernatants were tested for inhibitory activity on NK cell activity and lymphocyte transformation.
Results. The increment of sIL-2R in HIV-infected patients was confirmed, but in our series subjects presenting with PGL showed significantly higher sIL-2R levels than asymptomatic individuals (p 0.001). Increased sIL-2R were strongly correlated with neopterin and beta-2m serum levels whereas no correlation was found with CD4+ cell counts, CD4+/CD8+ ratios, activated T cells (CD3+, HLA-DR) or serum IgA. Follow up studies showed an increase of sIL-2R with time and without clinical evidence for progression. Follow up studies in AZT-treated patients will also be presented. Analysis of the in vitro studies is still ongoing and will be reported at the meeting.
Conclusion. The data strongly suggest that elevated sIL-2R in HIV infection reflect rather monocyte and possibly B cell alterations than T cell activation and/or destruction. The significance of sIL-2R as a marker for progression will be discussed as well as their contribution to the immune defect.

T.C.P.44

LOW LEVELS OF LFA1+ CELLS IN HIV INFECTION

Amiel, Corinne; Gobert,B.; May,Th.; Bene,MC.; Faure,G.; Canton,Ph. Department of Infect.Diseases and Lab.Immunology. CHU Nancy France

Objective: LFA1 (Leukocyte Function Antigen 1) is a membrane molecule of the adhesin family, involved in cell-cell interactions, and physiologically expressed on more than 90% nucleated cells in the peripheral blood (PB). In a previous study, we established that significantly lower percentages and numbers of PB lymphocytes expressed this molecule in HIV-infected patients. These data suggested that a decrease in LFA1 expression could be involved in the immunodeficiency of HIV+ and AIDS patients. This observation was confirmed in a new series of patients, and a follow-up study was performed.
Methods: LFA1 expression on PB lymphocytes was studied using classical indirect immunofluorecence techniques with a monoclonal antibody from Immunotech (Luminy-France). Patients were divided in two groups, accor--ding to CDC classification (group 1= stage II and III; group 2=IVC1 and IVD).
Results: In spite of careful monitoring and therapeutic attempts with AZT, low levels of LFA1+ cells persisted in initially "low" patients. Patients with a progressive decrease of LFA1+ cell percentage under 30% were developing AIDS-disease at this time.
No correlation was found for the two groups between CD4+ cells count and LFA1+ cells, no more between CD8 and LFA1.
Conclusion: LFA1 expression in HIV infection is significantly decreased, adding to the immune deficiency of CD4+ cells, and could represent a new predictive factor of AIDS on a long-term follow-up.

T.C.P.45

EXPRESSION OF THE T-CELL RECEPTOR MOLECULE IN HIV INFECTION

Amiel,Corinne; Bene,MC; May,Th; Faure,G; Canton,Ph.
Department of Infectious Diseases and Lab. Immunology. CHU Nancy - FRANCE.

Objective: T lymphocytes recognize foreign molecules using the T-cell receptor (TCR), a disulfide-linked heterodimer, closely associated with the CD3 polypeptide on the cell surface. We studied in a series of 150 HIV+ patients, the expression of the TCR molecule in addition to those of CD3, CD4, CD8 and LFA1 (adhesin) molecules, on peripheral blood lympho--cytes (PBL).
Methods: Classical indirect immunofluorescence techniques were used, with monoclonal antibodies from Coulterclone (for CD3,CD4,CD8), Immunotech (for LFA1) and Becton-Dickinson (for TCR-alpha chain).
HIV+ patients were divided in two groups, according to CDC classification: group 1 = stage II and III (N=100); group 2 = stage IVC1 and IVD (N=50).
Results: As expected, a highly signicant correlation was found between CD3 and TCR + cells'percentages, in both group. But TCR percentages (respectively 48,7 and 31,2 for groups 1 and 2) were constantly lower than CD3 (61,4 and 57,7). The TCR/CD3 ratio was 0,8 (gr.1) and 0,5 (gr.2).,
Conclusion: These data show a defective expression of TCR, occuring even at an early stage of HIV infection. This may add to the immune deficiency.

T.C.P.46

MOST SERA FROM HIV INFECTED INDIVIDUALS CONTAINS HIV ANTIGEN AS IMMUME COMPLEXES

Mahanian, Parvnez*; Huskins, K.**; Stehn, S.*; Deaas, R.*** and Fahey J.L.*
*UCLA Schools of Medicine and **Public Health, Los Angeles, CA, USA, ***E.I.DuPont Co., Glasgow Site, Wilmington, DE, USA

Objective: To develop a method for improved detection and quantitation of HIV p24 antigen and to check whether the lack of detectable HIV antigen within the vast window of asymptomatic HIV seropositivity could be due to low or absent synthesis of viral antigen or to formation of immune complexes which make antigen undetectable by available methods.
Methods: Dissociation of immune complexes and denaturation of antibodies with little or no compromise of HIV antigen by low pH treatment of the samples before standard p24 ELISA.
Results: In control experiments with artificial mixtures of HIV antigen and HIV antibody negative or positive sera it was demonstrated that: 1) no false positive results were caused by the treatment, 2) both HIV antigen positivity (4% vs 98%) as well as the amount of measured antigen were significantly increased, 3) while only some HIV antibody positive sera contain free antigen, in many sera the antigen is in the form of immune complexes not directly detectable by ELISA.
Randomly selected HIV antibody positive sera (n=416) from asymptomatic persons were tested for p24 antigen in parallel without treatment and after acid pretreatment. Substantial increase of p24 antigen positivity (51.7% vs 11.8%) and level (factor 2.8) were observed after pretreatment. Similar increase (58.7% vs. 34.8%) was observed for the group of 46 tested AIDS sera. Thus an additional 40% of sera from both groups contain p24 antigen in the form of immune complexes which are detected by our method. Sera from four consecutive visits (18 month period, 6 month interval) of 29 retrospective seroconverters were tested for presence of p24 antigen after dissociation of immune complexes. Eleven individuals (37.9%) never express any kind of detectable antigen; two (6.9%) showed episodical p24 positivity and 16 (55.2%) persistently contain p24, once it appears in their serum. The antigen can be detected directly only at periods when antibody-antigen ratio is low. At higher ratio p24 antigen is present in serum as immunocomplexes and can be detected only after dissociation.
Conclusions: Many sera from HIV infected individuals contain HIV antigen. It is mainly in the form of immune complexes and can be detected by the proposed method. The results suggest two main patterns of p24 antigen expression in sera. One group of individuals never expresses HIV antigen, another relatively large group persistently shows p24 and only a small group shows episodical p24 positivity.

T.C.P.47

PRODUCTIVE IN VITRO HIV INFECTION OF NORMAL CD8$^+$ LYMPHOCYTES

Bailey, Richard W.[1] and Lewis, D.E.[1,2]
[1]Howard Hughes Medical Institute, [2]Department of Microbiology and Immunology, Baylor College of Medicine, Houston, TX, U.S.A.

An increase in the numbers of CD8$^+$ lymphocytes occurs early in HIV infection. The role of CD8$^+$ cells in HIV infection is not clear; however, several laboratories have shown that CD8$^+$ cellular function is abnormal. In order to develop an in vitro system to study the effects of HIV infection on normal CD8$^+$ T cells, peripheral blood lymphocytes (PBLs) from HIV-negative donors were cultured with phytohemagglutinin (PHA) for 3 days and then infected with HTLV-IIIB. After reculture for 3 days, infected cells were irradiated and cocultured with uninfected PHA-stimulated PBLs from the same donor. Previous results indicated that most CD4$^+$ cells are depleted in such cultures after 6 days (FASEB J. 2:251, 1988). Cocultures and control uninfected cultures were grown in recombinant interleukin 2 for more than 3 months. HIV was monitored by electron microscopy and by p24 antigen ELISA. Cocultures were strongly positive for HIV p24 whereas uninfected control cells were negative. On day 26 after the start of the cocultures, cells were sorted into CD8$^-$ and CD8$^+$ cellular fractions. The sorted infected CD8$^+$ fraction was strongly positive for HIV p24 (1.34ng/ml); however, the CD8$^-$ infected fraction was only weakly positive (0.124ng/ml) when compared to H9-infected control cells (1.657 ng/ml). Thus, CD8$^+$ cells can become productively but noncytopathically infected with HIV. This may result from the development of a CD4$^+$ CD8$^+$ intermediary cell or after direct cell-to-cell transmission. The relevance of this data to the CD8$^+$ cellular abnormalities in vivo is unclear but suggests that HIV interactions may be more complicated than previously appreciated.

T.C.P.48

CD4-DERIVED PEPTIDE PROTECTS CD4+ T CELLS FROM HIV-I INFECTION.

Orit Shaira-Nahor, Hana Golding, Luba K. Vujcic and Frank A. Robey, NIH, National Institute of Dental Research, NIH and FDA, Bethesda, Maryland, U.S.A.

Objective. To identify primary sequences within the CD4 molecule that may be involved in the binding of the HIV-1 envelope.
Methods. We synthesized various peptides corresponding to different domains of CD4 molecule. HIV-I gp120 (200 ng/ml) was pre-incubated with CD4-derived peptides before adding to CD4+ T cells. Binding was measured by staining cells with OKT4A or Leu3A using FACS analysis. HIV-I strains: IIIB, RF and ZAIRE were added to MOLT3 cells in the presence or absence of CD4-peptides. Blocking of syncytia formation was measured after 5 days.
Results. We identified a 20 amino acid peptide (aa 74-95) mapped to the V1-J1 junction of CD4 that could protect CD4+ T cells from infection by different, divergent strains of HIV-1 (at a concentration of 25-50 g/ml). A shorter fragment of the CD4-truncated peptide (aa 81-95) was needed at higher concentration (250 g/ml) in order to block 100% of syncytia formation following infection with HIV-I. Inhibition of giant cells formation was also seen when the peptide was added 24 h after the induction of viral infection. The CD4-peptide (74-95) and the shorter fragment (81-95) succeeded (in a similar efficiency) to block HIV-I gp120 binding to CEM T cells. All other CD4-derived peptides examined had no effect on gp120 binding and did not block giant cell formation induced by HIV-I. Antisera against this peptide provided partial (40%) protection against HIV-I gp120 binding to CD4+ T cells.
Conclusions. The CD4 region (74-95) participates in the CD4-mediating binding of the HIV-I virion, and may be of therapeutic value in blocking spread of the virus in infected individuals.

T.C.P.49 HIV-1 DISEASE STATUS AND SEROREACTIVITY TO GAG, POL, AND ENV GENE PRODUCTS

Shadduck, Phillip P.*; Grove, T.**; Chiang, C.S.**; McMillan, C.W.***; White, G.C.***; and Matthews, T.* *Duke University Medical Center, Durham, NC, USA, **SmithKline Bio-Science, Van Nuys, CA, USA, ***University of North Carolina, Chapel Hill, NC, USA

Objective. To determine possible relationships between HIV-1 disease status and seroreactivity to gag, pol, and env gene products.
Methods. Banked sera from 360 seropositive hemophiliacs were assayed for reactivity to synthetic envelope V3 loop peptides and 7 bacterial recombinant peptides (HIVAGEN). The latter represent hIV-1 (IIIB) gp120, gp41, p55, p24, and p66/RT. Disease status was determined by absolute T4 cell count and, when available, Walter-Reed stage.
Results. Correlations between seroreactivity to the various gene products and disease status were analyzed. Reactivity to the immunodominant envelope V3 loop peptides was compared to overall envelope reactivity. Since seroreactivity to the V3 loop suggests exposure to the corresponding virus isolates, the breadth of that reactivity in individual bleeds was examined over time. Broadening of that response in the hemophiliac population since 1985 is probably not due to exposure to newly infecting isolates but would rather suggest a mutation over time of the original genotypes present in the pre-1985 Factor VIII concentrates.
Conclusions. About 50% of the 360 sera were positive for the N-terminal gp120 recombinant fragment (avg. absorbance 380u), whereas 95% were positive for the C-terminal fragment (avg. absorbance 1273u). Reactivity to V3 loop peptides was only 5% for the IIIB peptide vs. 80% for MN.

T.C.P.50 PHENOTYPIC CHARACTERIZATION OF THE EXPANDED CD8Leu-7$^+$ CELL POPULATION IN PATIENTS WITH HIV INFECTION

Spina,Celsa A.; McCutchan, J.A. and Richman, D.D.
University of California, San Diego and the VA Medical Center, San Diego, Ca., USA.

Objective. To determine whether the abnormal subpopulation of CD8Leu-7$^+$ cells in HIV infection belongs to a specific subphenotype which can be characterized by co-expression of additional antigenic markers.
Methods. Highly enriched CD8 cells (90$^+$%) were isolated from peripheral blood specimens by negative selection through serial steps of "panning" and complement-mediated lysis. Dual-stain (FITC/PE) monoclonal antibody analysis was performed by automated flow cytometry on these CD8 cells, effectively giving a triple antigenic phenotype. Samples from 20 HIV seropositive subjects (6 asymptomatic, 12 ARC, 2 AIDS) were analysed and compared to 15 healthy, HIV seronegative controls (10 homosexual males, HM; 5 heterosexual males, HC).
Results. The T cell phenotype subpopulation of CD8Leu-7$^+$ is abnormally expanded in HIV seropositive subjects and comprises a major cell population in patients who are symptomatic: ARC/AIDS, mean of 40% (range, 18-60%); asymptomatic HIV$^+$, 30% (18-45%); HM controls, 23% (7-46%); HC, 9% (3-14%). Because HIV$^-$ homosexual men (HM) also show elevated levels of this cell subset, it has been questioned whether this population has any direct relationship to the disease process in HIV infection. Our study demonstrates that, in HIV$^+$ subjects, a major portion of the CD8Leu-7$^+$ subset expresses the cell activation marker Leu-17/OK-T10: 69% and 41% in ARC/AIDS and asymptomatic HIV$^+$, respectively. In the seronegative HM subjects, however, only a 20% of this subset shows activation. This expanded, activated CD8Leu-7$^+$ cell subset bears the α/β chain of TCR-1 (94%) and, therefore, is part of the mature T cell population and not of the NK population. Further characterization of the CD8Leu-7$^+$ cells shows that the portion which co-expresses the CD11b (Leu-15) marker is reduced in ARC/AIDS (28%) in comparison to asymptomatic HIV$^+$ (40%) and the HIV$^-$ controls (45-50%).
Conclusion. The expanded CD8Leu-7$^+$ cell subset found during HIV disease progression appears to be derived from a distinct cell subgroup which is phenotypically different from that found in uninfected subjects, and may prove to be functionally heterogeneous as well.

T.C.P.51 IMMUNODOMINANT EPITOPES OF GP120: A POTENTIAL OBSTACLE FOR VACCINE DEVELOPMENT

Syu , W.J., Du, B., Lee, W.R., Chang, R.D., Huang, M., Lee, Tun-Hou; et al.
Harvard School of Public Health, Boston, MA, U.S.A.

Objective. The mature gp120 has 18 cystaine residues that are conserved in nearly all HIV-1 isolates. The disulfide-bridge dependent epitopes of gp120 are immunologically more dominant than the disulfide-bridge independent epitopes. The predominant type of gp120 antibodies detected in seropositive people progressing to AIDS and in AIDS patients, are those directed to the disulfide-bridge dependent epitopes of gp120. Our working hypothesis is that disulfide-bridge dependent epitopes serve as immunodominant decoy and elicit largely non-protective antibodies. The objective of this study is to remove the immunodominant disulfide-bridge dependent epitopes from the HIV-1 gp120.

Methods. The approach of site-directed mutagenesis was carried out to replace cystain residues with other amino acids in gp120. The antigenicity of the genetically-modified gp120 was studied by radioimmunoprecipitation and Western Blot assays.

Conclusion. HIV-1 gp120 mutants that lost immunodominant epitopes yet remained infectious were identified. Such mutants may have a better potential to induce functionally important gp120 antibodies.

T.C.P.52 DIFFERENCES AMONG LYMPHOCYTE SUBPOPULATIONS IN HIV POSITIVE OR NEGATIVE HOMOSEXUAL AND HETEROSEXUAL MALES AS DETERMINED BY MULTIPARAMETER FLOW CYTOMETRY.

Schnizlein-Bick, Carol; Magier, M. R.; Jones, R.B.; Fife, K.H. and Walker, E.B. Dept. Medicine, Indiana Univ. Sch. of Med., Indianapolis, IN, U.S.A.

Four-color flow cytometry was used to determine surface antigens on peripheral blood lymphocytes. Volunteers included normal, heterosexual males (N=20), HIV(-) homosexual males (N=20), or HIV(+) homosexual males that were divided into two groups based on a total CD4/ml blood count of >500 (N=23), or <500 (N=23). Statistical significance was accepted at $p < 0.05$. The %CD8 lymphocytes was significantly greater in HIV(-) homosexuals (35%) compared to heterosexuals (29%) and even greater in the HIV(+) >500 group (45%) and <500 group (49%). The %CD8 cells that also expressed CD38, an activation antigen, but not CD45R (a marker which reflects inducer of suppression on the CD4 background), was significantly greater in the HIV(+) <500 group (7%) and >500 group (4%) compared to HIV(-) males (1%). The significant increase in CD8/CD38 expression between the <500 and >500 groups could be attributed to 7/23 individuals in the <500 group whose serum was positive for HIV p24 antigen. The %CD8 cells that expressed both CD38 and CD45R was significantly greater in the <500 group (6%) compared to the >500 group (3%), and could not be accounted for by p24(+) individuals. Therefore CD38 alone on CD8 cells may reflect active viral replication, whereas CD38 and CD45 on CD8 cells may represent a subset alteration that correlates with progression of the disease. This work was supported by PHS U10 AI 2589-01 AIDS.

T.C.P.53 ENVELOPE GLYCOPROTEINS OF HIV-1 INHIBIT EXPRESSION OF mRNA FOR IL-2 BUT NOT FOR IL-2R IN TETANUS-SPECIFIC T CELL CLONES

Oyaizu Naoki, Chirmule N, Hall W, Kalyanaraman V.S, Slade H and Pahwa S. Department of Pediatrics & Medicine, North Shore University Hospital, Cornell University Medical College, Manhasset NY, & Bionetics Research Inc., Rockville MD. U.S.A.

Objective: To determine whether IL-2 and IL-2 receptor (IL-2R) gene expression are suppressed by the envelope glycoproteins of HIV-1 (gp120).
Methods: Gp120 was purified from HTLV-3$_{451}$ infected Hut 78 cell culture supernatants by affinity chromatography. Tetanus antigen-specific T cell clones independent of exogenous IL-2 were developed from a normal individual. The mRNA for IL-2 and IL-2R were determined by specific cDNA probes by northern blot analysis.
Results: Cloned T cells proliferated and expressed mRNA for IL-2 or IL-2R only when cultured in presence of tetanus antigen. Preincubation of the cloned T cells for 6 hours with 0.1 to 0.001 ug/ml of gp120 resulted in dose dependent suppression of mRNA for IL-2 and of tetanus-specific proliferative responses. Although the cells that had been treated with gp120 showed a significant decrease in their ability to express IL-2R (tested by staining with anti-IL2R mAb and analysed by flow cytometry), the IL-2R gene expression was not suppressed. In T cell clones stimulated with mAb directed against surface molecules CD2 and CD28 (plus PMA), proliferative responses and mRNA for IL-2 and IL-2R were unaffected by gp120 treatment.
Conclusion: The results demonstrate that gp120 selectively inhibits antigen-specific T cell responses by inhibiting IL-2 mRNA. Suppression of IL-2R expression by gp120 appears to occur at a post-transcriptional level.

T.C.P.54 INTERFERON-BETA and INTERLEUKIN-2 BUT NOT INTERFERON-ALPHA AUGMENT NATURAL KILLING OF HIV-INFECTED TARGETS AMONG HIV(+) SUBJECTS.

Ramsey, Keith M., Stanton, GJ, Cloyd, MW. University of Texas Medical Branch, Galveston, Texas, USA.

Objective: To evaluate the effects of recombinant interferons (rIFN) and interleukin-2 (rIL-2) on natural killer cytotoxicity (NKC) of HIV (+) and (-) individuals against HIV-1 infected targets.
Methods: Ficoll-hypaque separated peripheral blood mononuclear cells from HIV(-) and both Group II asymptomatic (Gp II) and Group IV symptomatic (Gp IV) HIV (+) individuals were incubated for 18 hrs with medium, 1000 U rIFNα or rIFNβser, or 50 U/ml rIL-2 prior to a 4-hr ^{51}Cr-release assay against CEM infected with HIVpm-213. NKC is expressed in lytic units per 10^7 cells at 30% lysis (LU/10^7), and analysed by Student's t-test.
Results: Mean NKC of controls was 38 LU for controls (n=12), 17 LU for GpII HIV(+) (n=8), and 10 LU for GpIV (n=10) HIV(+) (both <.05). Significant ($p<.05$) augmentation of NKC by rIL-2 occurred among all groups (213 LU, 100 LU, and 64 LU), as did augmentation by rIFNβ ser (96 LU, 53 LU, and 41 LU). There was no signficant augmentation of NKC by rIFNα except among controls (84 LU).
Conclusion: NKC against HIV-infected cells is significantly decreased ($p <.05$) with each stage of HIV infection; in addition, augmentation of NKC by rIFNβ and rIL-2 but not rIFNα may suggest 1) an effect of HIV on IFNα-responsiveness of NKC, and 2) potential for immunoreconstitution with IFNβser or IL-2 among HIV (+) individuals.

T.C.P.55 CORRELATION OF ADCC AND NEUTRALISATION WITH A BETTER CLINICAL STAGE IN CHILDREN BORN TO HIV-1-INFECTED MOTHERS

Kristina Ljunggren, V. Moschese, PA Broliden, B. Wahren, P. Rossi, M. Jondal
Dept. of Immunology, Karolinska Institute, Dept. of Virology, National Bact. Laboratory, Stockholm, Sweden.

Factors determining an uninfected or infected outcome as well as disease progression in children born to HIV-1 infected mothers are unclear. Also, early diagnosis is hampered by maternally transferred antibodies. We have retrospectively divided children, 0-24 months of age, into two groups based on HIV seroreactivity at 15 months of age. No difference was seen in presence of ADCC and neutralising antibodies between the groups. The persistently seropositive group was divided into a non-AIDS and AIDS group according to clinical status at time of serum collection. Interestingly, the ADCC frequencies in these two groups differed, 70% and 30%, respectively. Even more striking, 63% of non-AIDS and none of the AIDS patients had neutralising antibodies. These differences were not merely a reflection of decreasing IgG-titres in later stages of disease. Presence of both ADCC and neutralisation was more common in mothers giving birth to children becoming seronegative than to persistently seropositive ones.

In conclusion, ADCC and neutralising antibodies do not seem to protect against virus transmission from mother to child but are significantly correlated with a better clinical stage of HIV-infection.

T.C.P.56 AN ANALYSIS OF THE EXPRESSION OF CD4 RECEPTORS BY BLOOD MONOCYTES AND T CELLS FROM NORMAL AND HIV-1+ INDIVIDUALS.

Filion, Lionel G., Izaguirre,C. G.E Barber, L. Huebsch.
University of Ottawa, Ottawa, Canada K1H 8M5.

Monocytes harbor HIV-1 and probably play an important role in maintaining the chronicity of the disease. Monocytes are susceptible to HIV infection because they have the CD4 receptor. Objective: to compare the expression of CD4 on T cells and monocytes. Methods: An immunofluorescence (Flow cytometry, microscopy) analysis employing anti-CD4 (Leu-3a) and anti-CD14 (Leu-M3) on fresh monocytes and T cells was done. Results: 1) By flow cytometry 85-95% of monocytes from a normal(n=8) or HIV-1+ (n=4) individuals show dual positivity for CD14 and CD4. Although the analysis subtracts non-specific staining, staining with anti-CD4 causes a shift of the whole monocyte population along the fluorescence intensity axis as opposed to the tailing effect of control antibodies that did not alter the position of the fluorescence negative monocytes. These observation suggest that all monocytes are CD4+ albeit some have low CD4 density and overlap with background control staining. The results are not affected by fixation of cells or blocking of Fc receptors before staining, 2) The results were confirmed by two color fluorescence microscopy (>76% of CD14+ monocytes were also CD4+), 3) By two-color immunofluorescence microscopy, CD14+ monocytes have intracellular CD4 receptors whereas CD4+ T cells expressed nil to low levels of CD4. Conclusion: These results confirm and extend the observation that all monocytes are CD4+, contain larger amounts of intracellular CD4. HIV-1 infection did not seem to affect CD4 expression by monocytes which may help to explain the cytopathic effects of HIV-1 in monocytes and T cells.

T.C.P.57 ~~AUGMENTATION OF MONCOTYE MEDIATED DIRECT CYTOTOXICITY AND~~ ADCC BY AIDS PERIPHERAL BLOOD DERIVED MONOCYTES

Bonavida Benjamin; Jewett A.; Nishanian P.; and Mitsuyasu R.
Department of Microbiology and Immunology and Department of Medicine, University of California, Los Angeles, USA.

Cytotoxic effector mechanisms may play an important role in both the control and pathogenesis of HIV infection. We examined the cytotoxic activity of peripheral blood derived monocytes (PBM) from AIDS patients. Both direct cytotoxicity and antibody dependent cellular cytotoxicity (ADCC) were examined using tumor cells as targets in an 18 h ^{51}Cr release assay. Whereas normal PBM were minimally cytotoxic, PBM from AIDS patients were cytotoxic in the absence of exogenous activation. The level of cytotoxicity was comparable to IFN-γ activated normal PBM. Cytotoxicity was mediated by TNF as a) it was blocked by anti-TNF antibody and b) supernatant derived from the monocytes cultures contained high levels of TNF as assessed by cytotoxicity and by RIA. We then examined the PBM dependent ADCC using a target cell resistant to direct cytotoxicity but sensitive in the presence of anti-target antibody. PBM from AIDS patients had augmented ADCC whereas normal PBM were minimally cytotoxic. These results demonstrate that AIDS PBM are activated in vivo and mediate both direct and antibody dependent cytotoxicity. To test cytotoxicity to HIV infected targets, CD4$^+$ T targets resistant to PBM were required. Thus, we selected a variant CD4$^+$ CEM target that was resistant to monocyte-mediated cytotoxicity. These targets retain their CD4$^+$ phenotypes and bind HIV like control. We have initiated studies to use these HIV coated or infected targets with AIDS PBM. The results of such experiments and their significance will be presented.

T.C.P.58 MONOCYTE/MACROPHAGES INFECTED WITH HIV-1 PRODUCE ACID-LABILE INTERFERON-α

Szebeni, Janos*; Friedman R.M.**; Wahl, S.M.***; Wahl, L.M.*** and Weinstein, J.N.*
*National Cancer Institute, National Institutes of Health (NIH), **Uniformed Services, University of the Health Sciences, ***National Institute of Dental Research, NIH, Bethesda, Maryland, USA.

Objective. To describe an interferon (IFN) produced by HIV-1-infected monocyte/macrophages (M/M) and to establish the kinetics of its production.
Methods. M/M cultures were infected with HIV/HTLV-III$_{BaL}$/1985, and p24 antigen production was measured by ELISA. The controls were HIV-1-infected cells treated with AZT and non-infected cells. IFN titers in the culture medium were determined at intervals using human foreskin fibroblasts and murine encephalomyocarditis virus as a test system. Anti-IFN antibodies were used to distinguish among IFN types.
Results. We found significant production of IFN (>10 I.U./ml) by M/M infected with HIV-1 and cultivated for ≥12 days, whereas IFN production was not detectable in non-infected cells or in infected cells in which viral replication was eliminated by AZT treatment. The antiviral effect of this IFN in the test system was neutralized by anti-IFN-α antibody and reduced 80 - 90% by treatment at pH 2, suggesting that this IFN belongs to the acid-labile subclass of IFN-α.
Conclusion. Our observations suggest the M/M as a source of the acid-labile IFN-α that has been detected in AIDS patients and reported to be a useful prognostic indicator for development of AIDS. This IFN might also play a role in the pathogenesis of AIDS and its symptomatology.

T.C.P.59 CHARACTERIZATION OF HUMAN MONOCLONAL ANTIBODIES AGAINST HIV-1 WITH GROUP SPECIFIC NEUTRALIZING ACTIVITIES

Veronique, Boyer*; Madaule, P.**; Souche, S.*; Zagury, D.***and Desgranges , C.*
* INSERM U 271, Lyon, France; ** CNRS, Gif-sur-Yvette, France; ***Universite P et M Curie, Paris, France.

Objective. To obtain human monoclonal antibodies (HMAbs) against the proteins of HIV with neutralizing activity from vaccinated or infected individuals.
Methods. B lymphocytes from individuals vaccinated with a recombinant gp160-vaccinia virus or from infected donors were transformed with Epstein-Barr virus. Clones were then selected and analyzed for their reactivity with HIV proteins by several methods such as immunofluorescence, ELISA and immunoblot. A few HMAbs were mapped using a library of the HTLV III B strain cDNA, expressed in the yeast model. Divergent strains of HIV (HTLV IIIB and RF) were then used in neutralization assays based on virion infectivity and HIV mediated cell fusion.
Results. Clones secreting IgG anti-gp41 and gp120 were obtained. Epitope recognized by the anti-gp41 was localized within the C terminal region of gp41, between 824 and 848 amino acids. Virion infectivity can be blocked by the anti-gp41 and the anti-gp120, whereas no neutralization has been observed in the HIV mediated cell fusion assay.
Conclusion. The neutralizing potential of the HMAbs described here is therefore group-specific. Human monoclonal antibodies directed against conserved regions of HIV proteins allow to define immunodominant epitopes for vaccination and production of anti-idiotypes. Since they recognize divergent strains, use of HMAbs in passive therapy should be considered.

T.C.P.60 AUTOANTIBODIES AGAINST COLLAGEN IN AIDS; CORRELATION WITH RISK FACTORS AND DISEASE PROGRESSION

Grant, Michael D.*; Weaver, M.S.** and Hoffmann, G.W.* *University of British Columbia, Vancouver, B.C., Canada ** St. Pauls Hospital, Vancouver, B.C., Canada.

Autoimmunity often precedes the onset of ARC or AIDS, and a number of autoantibodies have been described in AIDS patients and in persons at risk for AIDS. Such antibodies raise the question of autoimmunity as a component of AIDS pathogenesis. We here report evidence of an autoantibody (anti-collagen) that occurs in all AIDS patients studied. Sera from various groups were assayed by ELISA for reactivity with gelatin. The specificity of this ELISA for anti-collagen activity was shown by inhibition with purified human collagens. High titre serum reactivity against collagen was found in all AIDS patients, HIV$^+$ homosexuals (66%), HIV$^-$ homosexuals (32%), and HIV$^+$ hemophiliacs (17%), but not in HIV$^-$ hemophiliacs, rheumatoid arthritis (RA) patients, or controls. Serum IgG levels showed little correlation with anti-collagen activity so this is not a reflection of polyclonal B-cell activation. Titration of anti-collagen activity in positive sera revealed levels 100 times higher than the levels in normal sera. Affinity purification followed by electrophoretic and immunoblot analysis confirmed the antibody nature of the anti-collagen reactivity. The anti-collagen antibodies react preferentially with primary determinants revealed after heat denaturation. In this respect, the antibodies are different from those described in RA, but similar to those observed in graft versus host disease and leprosy. To our knowledge, this is the first demonstration of autoantibodies of a single specificity present in all AIDS patients studied. These results suggest that all persons progressing to AIDS express anti-collagen antibodies which may be useful markers of disease progression.

T.C.P.61 POTENTIAL EXTRACORPOREAL TREATMENTS USING A CD8 T-ACTIVATOR FOR PATIENTS WITH AIDS.

Dewey J. Moody*, A. Mizerek-Erhart*, L.A. Feeney*, S. Finch-Manzagol*, H. Hollander**, T.B. Okarma*. Applied ImmuneSciences*, Menlo Park and University of California at San Francisco AIDS Clinic**, San Francisco, CA. U.S.A.

Objective. We designed a system to collect and grow autologous CD8+ T cells for use in the extracorporeal treatment of HIV-infected people. We hypothesized that the CD8+ T cell population from HIV-infected people contains useful effector cells.

Methods. A solid phase system with covalently attached anti-CD8 antibody was used to capture the cells from peripheral blood samples. Purified CD8+ T cells were grown ex vivo under the influence of interleukins for a period of two weeks. Functional assays were performed at that time.

Results. The captured cells were activated and grown ex vivo in the presence of IL2. Cultured cells were greater than 95% CD8+ and demonstrated viability greater than 95%. The CD8+ T cells exerted a strong lytic (30-60% lysis) response to various targets at an effector to target ratio of 5:1. The lytic activity of cells obtained from HIV-infected people was equivalent to that obtained from healthy control cells. The cells maintained a relatively stable phenotype and expanded quickly over the two week culture period. No evidence of the generation of transformed cells was observed indicating that the CD8+ cells did not lose their dependence on exogenously supplied growth factors. The CD8+ cells from infected donors were capable of repressing the outgrowth of HIV from autologous CD4+ cells, as measured by the presence of HIV p24 antigen in supernatant fluids.

Conclusions. The data presented support the application of this technology in the treatment of the clinical symptoms resulting from infection with HIV. Evidence supports the hypothesis that HIV-infected people have functional circulating CD8+ T cells that can be expanded in vitro.

T.C.P.62 ANTI LYMPHOCYTE ANTIBODIES ASSOCIATED WITH HIV INFECTION.

Cronin, William; Dorsett B.D. and Ioachim H.L. Department of Pathology, Lenox Hill Hospital, New York, N.Y. USA.

To determine the incidence of antilymphocyte antibodies (ALA) in patients with AIDS we examined the sera of 300 patients, and found 88% had significant levels of ALA as compared to only 8% of patients with non AIDS-related diseases. In a prospective study to evaluate the usefulness of ALA in assessing the risk of HIV positive individuals developing AIDS, 61 patients with ARC and 87 apparently healthy homosexual males (34 were HIV positive) were tested for ALA and followed for 18-36 months. During this interval 31 ARC patients with elevated ALA developed AIDS, while none of 15 ARC patients without ALA progressed to AIDS. Of the 34 HIV positive healthy homosexuals, 16 had elevated ALA and of these, 7 progressed to ARC or AIDS. None of the individuals with low levels of ALA have yet progressed to ARC or AIDS.

To determine whether AIDS sera containing elevated ALA might influence lymphocyte function we examined the effect of these sera on PHA response of normal blood lymphocytes. Short term cultures were pretreated with ALA positive AIDS sera, and flow cytometric measurements of proliferating cells demonstrated substantial reduction (40-95%) of PHA stimulation. Absorption of AIDS sera with normal donor lymphocytes abolished ALA activity without affecting anti-HIV antibody levels, or abrogation of PHA response.

The determination of ALA levels may be a useful prognostic indication for the monitoring of HIV infected individuals.

T.C.P.63 PREFERENTIAL LOSS OF LEU 8^{-}, CD45R^{-}, HLA-DR^{+} CD8 CELLS DURING CULTURE OF MONONUCLEAR CELLS FROM FORMER BLOOD DONORS SEROPOSITIVE FOR HIV-1.

Prince, Harry. American Red Cross Blood Services, Los Angeles, California USA

Objective. To quantitate changes in CD4 and CD8 cell subsets during in vitro culture of mononuclear cells (MC) from persons seropositive for HIV-1.

Methods. MC from Controls (N=26) or former blood donors seropositive for HIV (N=28) were suspended in culture medium at 2 million lymphocytes/ml. Some cell aliquots (0.1 ml/aliquot) were placed in microtiter wells and cultured for 3 days without a stimulus. Identical aliquots were used to measure day 0 levels of CD4 and CD8 cell subsets. Quantitation was achieved using a Spectrum III flow cytometer, which counts the number of cells (sip count) in a constant volume of cell suspension. The sip count for cells of a given phenotype thus reflects the actual concentration in the suspension. Similarly, sip counts were again measured after culture (day 3).

Results. Relative recoveries (RR) of lymphocytes, CD4 cells, and CD8 cells were significantly lower in the HIV group than the Control group; for the HIV group, CD8 RR was significantly lower than CD4 RR. Dual-color cytofluorometry showed that CD8 cell loss in the HIV group occurred preferentially within subsets defined as Leu 8^{-}, CD45R^{-}, and HLA-DR^{+}; in contrast, CD8 cell loss was nonpreferential for subsets defined by Leu 7 expression. CD8 cell loss also occurred when purified CD8 cells were cultured for 3 days.

Conclusion. Some CD8 cells from HIV-infected persons do not survive during short-term culture. The predominant phenotype of the CD8 cells lost (Leu 8^{-} CD45R^{-} HLA-DR^{+}) is characteristic of activated CD8 cells.

(Supported by funds from ARCBS Biomedical Research and Development.)

T.C.P.64 INVERSE ABERRANCIES OF THE MUCOSAL AND SYSTEMIC IGA SYSTEMS IN AIDS PATIENTS.

Jackson, Susan*; Kotler, D.**
* UAB, Birmingham, AL USA, **St. Luke's Roosevelt Hosp, New York, NY, USA

Objective. To describe anomalies of IgA in serum and external secretions of patients with AIDS.

Methods. It is well-documented that levels of total serum IgA in AIDS patients are often markedly and selectively increased; we have further shown that elevated levels of immune complexes in this disease can primarily be attributed to subclass-restricted IgA. Others have demonstrated the presence of IgA antibodies to HIV in saliva and cervical secretions. All of these findings indicate a profound involvement of both the systemic and mucosal IgA systems in this disease. We have initiated experiments to characterize secretory IgA in AIDS in order to determine if alterations of this component of the IgA system, similar to those often observed in its systemic counterpart, can be identified. In order to determine if the secretory IgA system was quantitatively affected in a manner similar to that of its serum analogue, 15 samples of whole saliva obtained from normal volunteers along with 28 such samples from patients with AIDS were assayed by quantitative ELISA for levels of IgA subclasses.

Results. Levels of salivary IgA1 ranged from 8.9-82.2 µg/ml (geometric mean=22.9) and from 6.0-96.0 µg/ml (g.m.=21.1) in the control and AIDS populations, respectively. (P=N.S.) On the other hand, **salivary IgA2 levels ranged from 8.3-72.5 µg/ml (g.m.=28.3) and from 1.2-72.7 µg/ml (g.m.=6.2) in the same two populations ($P < 0.0001$).**

Conclusion. IgA is composed of 2 subclasses (IgA1 and IgA2), which are present in serum and external secretions in different proportions. **IgA2 constitutes at least 40% of total secretory IgA; in contrast, it is a relatively minor component of serum IgA. Since a major mucosal (but not serum) IgA subclass is selectively diminished in AIDS (as opposed to elevations in total serum IgA), we conclude that the systemic and mucosal IgA systems appear to be inversely affected in this disease.**

T.C.P.65 EPITOPE MAPPING OF MONOCLONAL ANTIBODIES AGAINST HIV-1 STRUCTURAL PROTEINS USING PEPTIDES

Niedrig, M.*; Hinkula, J.**; Weigelt, W.*; Thiele, B.*; L'age-Stehr, J.***; Pauli, G.* ; Rosen, J.**** & Wahren, B.**.
* AIDS-Zentrum am Bundesgesundheitsamt, Berlin, F.R.G. ** National Bacteriological Laboratory, Stockholm, Sweden. *** Robert Koch-Institut des Bundesgesundheitsamtes, Berlin, F.R.G.; **** Johnson & Johnson, Biotechnology Center, La Jolla, CA, USA

Murine monoclonal antibodies (Mab) directed against the structural proteins p17 and p24 of HIV-1 were investigated in an epitope mapping system. Overlapping peptides consisting of 15 amino acids of the p17 and p24 protein, were synthesized in solid phase. These peptides were investigated in inhibition assays. Three different immunogenic regions (region A, B and C) could be defined, one on p17 and two on p24. As expected, the monoclonal antibody 3-H-7 reacting with p17 in immunoblotting was inhibited by peptides originating in the p17 amino acid sequence KKAQQAAADT, position aa 113-122 (region A). On p24 two different regions of reactivity were observed. Region B comprised reactivity for 20 recloned Mabs, but with slightly different rectivity in the centrally located aa EAAEW epitopic site. The antibody 12-B-4 crossreacting with HIV-2 and SIVmac, recognized region C on p24 aa position 293-302. Recognized epitopes were characterized using computer analysis according to Hopp & Woods and Chou & Fasman.

T.C.P.66 EVALUATION OF MONONUCLEAR CELL ASSOCIATED HIV ANTIGEN IN INFANTS AND CHILDREN

Robb, Merlin L.*; Baker, J.*; Toro, L.*; Vincent, J.*; Pettett, G.**; Fischer, G.**; and the Walter Reed Retrovirus Research Group
*Walter Reed Army Medical Center, Washington, D.C., United States of America
**Uniformed Services University of Health Sciences, Bethesda, Maryland, United States of America

Objective. To determine the presence and distribution of mononuclear cell associated HIV antigen in infants and children.

Methods. Mononuclear cells were harvested from 1 to 3cc of heparinized whole blood using standard methods. The mononuclear fraction was diluted to 10^7 cells and paired aliquots were incubated with anti-leu 3a-PE anti-leu 4-PE and in selected cases, anti-leu M3-PE. These paired samples were then incubated with murine monoclonal anti-GP120 or anti-P24 and goat anti-murine IgG-FITC. The samples and control specimens were then analysed using FACS analysis.

Results. The children analysed for HIV infection ranged in age from birth to 11 years. P24 was identified on the cell membrane of both macrophages (leu M3 pos.) and T4 lymphocytes (leu 3a pos.) PG120 was seldom detected on either monocytes or lymphocytes. A striking pattern of monocyte associated antigen was identified in a young infant (4 mos.) with perinatal exposure. The density of P24 antigen and the percentage of cells expressing this antigen was much greater in the monocyte/macrophage population than the helper T-cell population.

Conclusion. These data suggest that HIV antigen is detectable on the mononuclear cells in infants and children and in infants is especially prominent in monocyte/macrophage cells.

T.C.P.67 SEQUENTIAL ANALYSIS OF HIV-SPECIFIC CTL FUNCTION IN HIV-INFECTED PATIENTS DURING AZT THERAPY

Hoffenbach, Agnès, Dadaglio, G., Michel, F., Chenciner, N., Sansonetti, P. and Plata, F.
*Institut Pasteur Paris - France

Objective : To measure the HIV-specific cytotoxic T lymphocyte (CTL) response in patients at different stages of HIV infection during the first six months of 3-azido-3-deoxythymidine (AZT) treatment.
Methods : PBL from 10 asymptomatic, ARC or AIDS patients, were collected sequentially during the first six months of AZT treatment. HIV-specific CTL in blood were detected directly or following in vitro stimulation with autologous HIV-infected lymphoblasts. Target cells were P815 tumor cells doubly transfected with the HIV-1 env, gag or nef gene and the HLA-A2 gene. In some patients effector CTL and CTL precursor cell frequencies were estimated by limiting dilution analysis.
Results : In most patients (7/10) CTL activity increased rapidly with AZT treatment. However, after 3 months, all patients showed a dramatic decrease in CTL activities. After 6 months CTL responses remained weak without reaching levels observed before AZT treatment.
Conclusions : 1) AZT treatment seems to exert an early but transient immunostimulating effect on CTL activities. 2) The constant drop in CTL function after three months treatment might reflect the decrease in viral antigen load and/or AZT toxicity. 3) CTL functions decline before biological and clinical deteriorations become apparent.

T.C.P.68 COMPLEMENT DEPOSITION ON THE SURFACE OF HIV-INFECTED CELLS MEDIATES BINDING TO CELLS CARRYING COMPLEMENT RECEPTORS

Sölder,Brigitte*,Schulz,T.*,Hengster,P.*,Bitterlich,G.*, Larcher,C.*,Wachter,H.**,Dierich,M.P.*
*Inst.f.Hygiene, **L.-Boltzmann Inst.f.AIDS-Research,Innsbruck, Austria

Objective: To investigate the biological significance of complement deposition on the surface of HIV-infected H9 cells.
Methods: HIV-infected cells, which had deposited C3 on their surfaces by incubation in normal human serum were added to complement receptor (CR) bearing target cells: human erythrocytes, U937, human macrophages and investigated for immune adherence.
Results: HIV-infected cells, when they had been incubated in human serum, specifically bound to all CR+ cells mentioned above, whereas uninfected cells did not. Heat-inactivation abolished this binding capacity indicating the role of the complement system. In the case of U937 immune adherence occurred only after stimulation with TPA, which enhances CR expression.
Conclusions: Complement deposition on the surface of HIV-infected H9 cells is able to mediate immune adherence to CR+ cells. We are presently investigating, whether this could lead to infection of CR+ cells characterizing complement receptors in addition to T4 and Fc receptors as another way to initiate infection of cells.
Supported by L.B.I., State of Tyrol, BMFT

T.C.P.69 FUNCTIONAL AND ENVELOPE BINDING ANTIBODIES TO HIV-1 IN SEROPOSITIVE SUBJECTS FROM AFRICA AND THE AMERICAS

Carrow, Emily*; Katzenstein, D.*; Sawyer, L.A.*; Hendry, R.M.*; Boone, E.J.*; Quinnan, G.V.*; et al**. *LRR, DV, Center for Biologics Evaluation and Research, FDA, Bethesda, MD, **Johns Hopkins School of Public Health, Baltimore, MD, Univ. of Zimbabwe, Harare, Zimbabwe, Fiocruz, Brazil, Project SIDA, Zaire.

Objective. To determine the quantitative relationship between HIV-1 envelope binding antibodies (BA) and neutralizing antibody (NA) and those directing antibody-dependent cell-mediated cytoxicity (ADCC) in individuals from different geographic regions.
Methods. Sera were obtained from HIV-infected individuals from the U.S., Haiti, Zaire, Zimbabwe, and Brazil. NA titers were determined by 50% reduction of syncytia in a microneutralization assay in MOLT-3 cells using HIV_{IIIB}. BA titers were determined using 4 commercial ELISAs and Western blot (WB). ADCC was measured in a 4-hour ^{51}Cr release assay using HeLa cells infected with vaccinia containing an HIV envelope insert.
Results. BA and WB titers using whole viral lysate and recombinant envelope protein ELISAs correlated significantly with NA titers in sera from the U.S., Haiti, and Brazil. In contrast, sera from Zaire had lower BA and WB titers that did not correlate with NA titers. There was no correlation between ADCC and either NA or BA titers in sera tested.
Conclusions. High BA titers to both whole viral lysate and recombinant envelope proteins predict NA in North and South Americans infected with HIV-1, but may be of less predictive value in Africans, possibly due to variation in envelope-specific epitopes. The discordance between NA and ADCC suggests that different antibodies mediate these responses.

T.C.P.70 THE TRANSMEMBRANE PROTEIN OF HIV-1, gp41, EXISTS IN VIRIONS IN THE FORM OF TETRAMERIC STRUCTURES WHICH POSSESS ENHANCED IMMUNOREACTIVITIES.

Abraham Pinter[1,3], William J. Honnen[1], Shermaine A. Tilley[1,3] Constantin Bona[2], Habib Zaghouani[2], Miroslaw K. Gorny[3], and Susan Zolla-Pazner[3,4]. [1]The Public Health Research Institute, [2]Mt. Sinai School of Medicine, [3]New York University Medical Center, [4]New York Veterans Administration Medical Center, New York, New York, U.S.A.

Objectives. To characterize the native structure of the HIV-1 transmembrane protein.
Methods. HIV proteins present in viral lysates were separated by SDS-PAGE, and analyzed by Western blotting, using monoclonal antibodies and anti-peptide sera specific for gp41. These antibodies were also used to characterize viral proteins resolved on various commercial HIV Western blotting kits.
Results. Western blot assays of HIV lysates performed with antibodies specific for gp41 invariably recognize a major component of 160 kDa and a less intense component of 120 kDa in viral lysates. We demonstrate that these species are noncovalently associated tetramers and trimers of gp41, which represent the native form of this protein in virions. These complexes are stable to boiling in the presence of low concentrations of SDS, but are dissociated to gp41 monomers at high SDS concentrations. Moreover, two human monoclonal antibodies preferentially recognize the oligomeric complexes over monomeric gp41 in Western blots, indicating the presence of epitopes recognized by the human immune system on the gp41 multimers which are not efficiently expressed by the dissociated monomers.
Conclusions. These studies demonstrate the existence of multimeric *env* complexes for HIV, and the enhanced and altered antigenicity of such multimers. Such oligomeric structures may be important in the design of subunit and recombinant HIV *env* vaccines.

T.C.P.71 IN VITRO ACTIVATION OF NATURAL KILLER(NK) CELLS BY INTERLEUKIN-2 (IL-2) OR INTERFERON-β (IFN-β) INDUCES THE LOSS OF CYTOTOXIC CAPACITY.

Dittel, Bonnie N.; Spear, G.T.; Landay, A.L. and Bray, R.A.
Dept. of Immunology/Microbiology, Rush Medical Center, Chicago, Illinois, USA.

Objective. To investigate the basis for the altered natural killer cell phenotype associated with loss of NK function observed in HIV Antibody positive (Ab^+) individuals.
Methods. Peripheral blood lymphocytes (PBL) were obtained from HIV Ab^- donors by density gradient seperation and depleted of monocytes by adherence. The PBL were incubated with HIV (RF or HTLV-IIIb strains, 1000 $TCID_{50}/10^6$ cells) and cultured for 6 days with or without IL-2 (recombinant or natural) or recombinant IFN-β (100 U/ml). $CD16^+/Leu\text{-}19^+$ cells were quantitated by flow cytometry before and after culture. NK and ADCC activity was assessed by a chromium release assay on days 3 and 6.
Results. When cells were cultured with HIV in the absence of IL-2 or rIFN-β, NK and ADCC activity against conventional tumor targets (K562 and I84) was not significantly altered. In contrast, PBL cultured with HIV and either IL-2 or rIFN-β exhibited a marked decrease in NK and ADCC (>50%). Phenotypic analysis of cells cultured with HIV but without lymphokines showed a small decrease in the percentage of $CD16^+/Leu\text{-}19^+$ cells while cells cultured with HIV and lymphokines showed a significant decrease in $CD16^+/Leu\text{-}19^+$ cells (>90%)
Conclusion. In vitro culture with HIV in the presence of an activation signal such as IL-2 or rIFN-β substantially reduces NK and ADCC function. This diminished activity is associated with and may be primarily due to the loss of $CD16^+/Leu\text{-}19^+$ cells. Thus, the decrease in NK activity observed in HIV Ab^+ individuals may be due to the loss of an NK cell subset.

T.C.P.72 UNIQUE AND CROSS-REACTIVE ANTIGENIC REGIONS WITHIN THE TRANSMEMBRANE PROTEINS OF HIV-1/HIV-2, AND THEIR UTILITY IN DIAGNOSIS OF VIRAL INFECTIONS.

Hunt J., Beardway K., Gutierrez R., Dawson G., Sarin V., and Devare, Sushil , Abbott Laboratories, North Chicago, Illinois, USA.

Objective. To identify antigenic regions within viral transmembrane proteins in order to differentiate HIV-1 infection from HIV-2.
Methods. Serum samples positive for antibodies to HIV-1 and HIV-2 were identified using HIV-1 and/or HIV-2 recombinant proteins on solid support. A selective population (25 sera) were further analyzed using 1) a competitive immunoassay employing synthetic polypeptides comprising immunodominant region (IDR) sequence from HIV-1 or HIV-2 transmembrane proteins and 2) site directed monoclonal antibodies as competitive probes against serum antibodies.
Results. Serum samples reacting with either recombinant transmembrane proteins of HIV-1 or HIV-2 were placed into one of four groups: 1) 8 samples containing only antibodies against HIV-1 gp41, 2) 6 samples containing only antibodies against HIV-2 gp41, 3) 4 samples which contained two distinct HIV-1 and HIV-2 antibody populations apparently indicating dual infection, and 4) 7 samples which appeared to contain antibodies exhibiting cross reactivity against HIV-transmembrane proteins. The results were confirmed using 1) specific monoclonal antibodies to either HIV-1 or HIV-2 and 2) radioimmunoprecipitation analysis of HIV-1 or HIV-2 infected labeled cell lysates.
Conclusions. These data support existance of unique and cross reactive epitopes within the transmembrane protein immunodominant regions of HIV-1 and HIV-2. In addition, a cross reactive epitope also is present and maps outside of the immunodominant regions.

T.C.P.73 HUMAN ANTIBODY RESPONSE TO HIV-1 PROTEASE ACCORDING TO DISEASE STAGE

Boucher, Charles*, De Jager M.*, Debouck Ch.**, De Wolf F.*, Wolfs T.*, Goudsmit J.*.
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, ** Department of Molecular Genetics, Smith Kline & French Laboratories, King of Prussia, PA, USA

Objective. To study the relationship between presence of antibodies to HIV-1 protease and presence of several disease predictive markers for disease progression in different infected risk groups (homosexuals, hemophiliacs).
Methods. Antibodies to HIV-1 were measured in serum using an enzyme linked immunosorbent assay using a bacterially expressed, recombinant form of HIV-1 protease. HIV-1 antibodies, HIV-1 antigen, HIV-1 core antibodies were measured using a commercially available EIA (Abbott Lab).
Results. From a prospectively followed cohort of homosexuals 56% (34/61) had antibodies to protease one year after HIV-1 Ab seroconversion, 63% (24/38) had antibodies two years after HIV-1 Ab seroconversion. A similar pattern was observed in 20 hemophiliacs. 63% (160/255) of HIV-1 Ab positive homosexuals in CDC stage II/III were anti-protease positive, versus 60% (9/15) of homosexuals with AIDS related complex (CDC IV A) and 36% of the homosexuals with AIDS (CDC IV B-E). In 255 homosexuals (CDC II/III) antibodies to protease were significantly more frequently found in samples lacking HIV-1 antigen ($p<0.001$) and possessing antibodies to HIV-1 core proteins ($p<0.001$).
Conclusion. HIV-1 protease is expressed and antigenic in most HIV-1 infected individuals and absence of antibodies to HIV-1 protease is more often found in persons with progressive disease.

T.C.P.74 QUANTITATIVE, NOT QUALITATIVE, DEFECTS CHARACTERIZE RESPONSES OF CELLS FROM HIV+ SUBJECTS TO B CELL MITOGENS.

Edelman, AS and Zolla-Pazner, S. NYU Med. Ctr. and V.A. Hospital NY, NY, U.S.A.

OBJECTIVE: To elucidate the immunoregulatory mechanisms involved in B lymphocyte responses of cells from HIV-seropositive (HIV+) subjects.
METHODS: Proliferative responses of mononuclear cells (MNC) to B cell mitogens, (anti-u and Staphylococcus aureus Cowan I [SAC]) were determined by 3H-thymidine incorporation in 3 or 4 day cultures. Mixed lymphocyte culture supernatant (MLC-sup) and indomethacin were added to certain cultures.
RESULTS: Average proliferative responses of MNC from HIV+ patients to each mitogen are significantly defective (25-35% of control [HIV-] responses). Addition of MLC-sup increases responses of both HIV+ and HIV- MNC to anti-u (45% and 90% respectively) and SAC (60% in both groups). Addition of indomethacin increases responses to SAC, (60-70% increase for both groups). Effects of MLC-sup and indomethacin are additive. To determine if deficient responses were influenced by the altered frequency of lymphocyte subsets in the HIV+ cultures, correlations were sought between proliferation and percent of lymphocyte subsets. Proliferative responses to anti-u and SAC in the presence of both MLC-sup and indomethacin are correlated positively with the percent of B and CD4+ T cells, and negatively with the percent of CD8+ T cells in culture. Mathematical correction of the data for the abnormal percentages of B, CD4+ T and CD8+ T cells results in responses that are comparable to those of control cells.
CONCLUSION: Deficient responses may be due to quantitative differences in the responding B cells and regulatory pathways mediated by CD4+ and CD8+ T cells and not to qualitative differences in the ability of the patients' B cells to respond to these mitogens.

T.C.P.75 HUMAN MONOCLONAL ANTIBODIES (HuMAb) TO HIV-1.

Lake, D.*; Kawamura, T.**; Morice, A.**; Masuho, Y.**; Petersen, E.*; and Hersh, E.*.
*Dept. of Hematology/Oncology, University of Arizona, Tucson, Arizona, 85724, USA, **Teijin Institute for Biomedical Research, Tokyo, Japan.

Objective. To develop a panel of human IgG monoclonal antibodies to HIV-1 that have therapeutic potential either alone or in combination with each other or with other anti-viral agents.
Methods. Hybridomas were produced by fusion of splenic or lymph node lymphocytes from HIV sero-positive patients with the P3x63AgU1 murine myeloma cell line. Hybridomas were screened for the production of anti-HIV IgG by ELISA and indirect immunofluorescence. ELISA screening was performed using plates coated with 2 different HIV-1 isolates and 1 plate coated with a gp120 synthetic peptide fragment. Cloning was done by limiting dilution.
Results. Eight HuMab have been developed that react with HIV.

HuMAb#	86	1	13	P5-3	S1-1	U7-2	V7-8	V10-9
Isotype	IgG1/κ	IgG1/λ	IgG1/λ	IgG1/λ	IgG1/λ	IgG1/κ	IgG1/κ	IgG1/κ
Recognized Antigen	gp160, 120,41	gp160, 120	gp160, 120	no rxn	no rxn	gp160, p55,24	p55,24	gp160, 120,41
I.F.	++	++	++	++	++	+/-	+/-	++
Activity	-	-	-	-	neutralizing	-	-	enhancing

Conclusion. We have established 8 anti HIV HuMAb, one of which has neutralizing activity. Such HuMAb should have major scientific, diagnostic and therapeutic applications. (Abbreviations IF: immunofluorescence, rxn: reaction)

T.C.P.76 FINE SPECIFICITY OF HIV-SPECIFIC CYTOTOXIC T LYMPHOCYTES IN HUMANS

Dadaglio, G.*, Langlade-Demoyen, Pierre*, Bahraoui, H.*, Fisher, R.° and Plata, F.*.
* Institut Pasteur Paris, France, °Biogen Research Corporation, MA, USA.

Objective : To identify CTL epitopes on glycoproteins coded by the HIV env gene.
Methods : HIV-specific HLA-A2 restricted CTL lines were generated from human peripheral blood lymphocytes by stimulation with autologous HIV infected lymphoblasts in the presence of interleukin 2. Peptides used were selected with the criterion of conservation among different HIV isolates in view of an eventual application in vaccines or immunotherapy. These peptides were tested for CTL recognition by incubating each peptide with 51Cr-labeled tumor target cells stably transformed with the human HLA-A2 gene.
Results, conclusions : Among the 30 peptides tested, 6 peptides were particularly well recognized. Results obtained with env synthetic peptides indicate that some epitopes recognized by HIV-specific CTL are highly conserved. This is encouraging in view of the large variability of HIV isolates.

T.C.P.77 HIV RECOMBINANT p18 CORE PROTEIN INHIBITS PROLIFERATIVE RESPONSES BY NORMAL LYMPHOCYTES IN HUMANS AND MICE.

Michel, Frédérique*, Cheynier, R.*, Lacaud, G.°, Rautmann, G.°, Guy, B.°, Kieny, M.P.°, Girard, M.** and Plata, F.*
*Institut Pasteur, Paris, °Transgène S.A., Strasbourg, **Pasteur Vaccins, Marnes-la-Coquette - France

Objective : To determine the in vitro effect of HIV-1 core p18 protein on mitogen-induced lymphoproliferative response and mixed lymphocyte reaction (MLR). To compare results with the effect of p18 in a mouse model.
Methods : Recombinant p18 gag, p25 gag or p27 nef protein was preincubated with peripheral blood lymphocytes (PBL) from normal donors. Polyclonal mitogenic responses to plant lectins and MLR were then studied in proliferation assays. The effect of p18 was also examined in normal BALB/c mice, and in mice immunized with a recombinant vaccinia virus containing the HIV-1 gag gene.
Results : P18 gag protein suppressed the proliferative responses of PBL from five different healthy donors when lymphocyte proliferation was induced by ConA or by HLA alloantigens in MLR. In contrast, p25 gag and p27 nef proteins had no suppressive effects. These results were reproducible with mouse lymphocytes : p18 gag protein suppressed mitogenic responses to ConA and PHA, as well as specific proliferative responses to p25 gag protein in mice vaccinated with a vaccinia virus-HIV gag recombinant.
Conclusions : 1) Immunosuppressive and immunogenic epitopes of HIV-1 proteins have to be defined in view of vaccination in humans. 2) The murine model is useful to evaluate the immunogenic power of different HIV proteins.

T.C.P.78 LOCALIZATION WITHIN THE HIV-1 LTR OF NUCLEOTIDES RESPONSIVE TO CMV-MEDIATED TRANSACTIVATION

Paul Luciw*, P. Barry*, E. Pratt-Lowe*, M. Marthas*, N. Duchange†, and K. Jones†. *Dept. of Medical Pathology, University of California, Davis, CA 95616 and † Molecular Biology and Virology Laboratory, The Salk Institute, La Jolla, CA,U.S.A.

Objective: To investigate the molecular basis by which human cytomegalovirus (CMV) activates expression from the HIV-1 long terminal repeat (LTR).
Methods: We are analyzing the molecular basis by which human CMV stimulates expression from the HIV-1 LTR by constructing recombinant plasmids with a reporter gene (CAT) under the transcriptional control of the LTR. Clustered-site mutations and small deletions have been introduced into the HIV-1 LTR. These mutants have been tested in transient expression assays in a variety of cell types, including transformed and non-transformed cells, for responsiveness to CMV IE and HIV-1 transactivator (tat).
Results: Mutations in the LTR around either the start site of transcription (-6 to +20), the three SP1 protein binding sites, or the TATA box dramatically reduce responsiveness to CMV IE. A mutation at -6 to -1 abolishes CMV IE-mediated transactivation but leaves tat-mediated transactivation intact. Mutations which abolish responsiveness to tat (+20 to +33) have little or no effect on CMV IE transactivation. Insertion of the -6 to +20 region of the HIV-1 LTR into a CMV IE non-responsive promoter confers responsiveness to CMV IE, but only in one orientation. The magnitude of transactivation by CMV IE and tat appears to be related to the transformation phenotype of the cell.
Conclusions: The mutation analysis shows that responsiveness of the HIV-1 LTR to CMV transactivation includes sequences recognized by the cellular factor designated leader binding protein-1 (LBP-1). Also, additional host factors which are involved in control of cell growth appear to play a role in transactivation of HIV by CMV.

T.C.P.79

Lymphokine-Activated Killer Cell Activity in Patients with AIDS. Chryssa Gryllis, Bluma Brenner, Richard Margolese, Mervyn Gornitsky, and Mark Wainberg. Lady Davis Institute for Medical Research of the Sir Mortimer B. Davis-Jewish General Hospital, Montreal, Quebec, Canada

Natural killer (NK) cell activity and NK cell cytotoxic subsets have been shown to be reduced in patients with AIDS-related disorders relative to healthy controls. The ability to generate lymphokine-activated killer (LAK) cells in AIDS has not yet been reported. Peripheral blood lymphocytes PBLs, (10^6 cells/ml) were incubated for 4-5 days with 15 U/ml recombinant IL-2 to generate such LAK cells. The ability of these activated killers to lyse a panel of targets was deduced using 18h ^{51}Cr release assays. Although there was a 45% decrease ($p<.001$, unpaired t-tests) of PBLs in the patients with AIDS compared to healthy males, the relative recovery of IL-2 activated lymphocytes was not significantly different for both populations. LAK activity against U-937, K562, and RAJ1 targets was reduced in patients with AIDS relative to control populations. However, the ability of patients with AIDS to lyse HIV-infected U-937 targets was not significantly different from healthy controls. LAK activity of healthy males was significantly greater against uninfected U-937 targets vs. their HIV-infected counterparts (151 ± 29.5 vs 87.2 ± 13.9 LU20/10^8 lymphocytes, $p<.05$, paired t-tests). In contrast, LAK activity in patients with AIDS showed enhanced kill of HIV-infected U-937 targets when compared to uninfected U937 cells (57.7 ± 10.6 vs 37.9 ± 6.3 LU20/10^8 lymphocytes, $p<.05$ paired t-tests). These preliminary results indicate that whereas LAK activity in patients with AIDS is impaired relative to controls, these populations vary in their spectra of target cell reactivity.

ANALYSIS OF THE MECHANISM UNDERLYING *REV* REGULATIO OF HIV STRUCTURAL PROTEIN GENE EXPRESSION

Hammarskjöld, Marie-Louise; Heimer, J. ; Smith, A.; Lewis, N.; Andrews, W.; and Rekosh, D. Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214 USA

Expression of HIV-1 env, gag and pol proteins is strictly dependent on co-expression of the rev protein even when SV40 based vector systems are used. These vectors produce large quantities of viral proteins and RNA and thus serve as convenient models to study the mechanism behind rev regulation. Using this system we have mapped an element normally present in the env and gag mRNAs that is required in cis for rev to act. The element is active only in one orientation. In the absence of rev or the rev-responsive element, levels of cytoplasmic mRNA for the structural proteins are dramatically decreased in transfected cells. In contrast, levels of total RNA (cytoplasmic plus nuclear) remain roughly the same whether or not rev is present. A direct analysis of nuclear RNA shows an accumulation of the RNAs for the structural proteins in the absence of rev. The results suggest that rev functions to regulate nuclear export of these mRNAs.

We are also examining rev regulation of the HIV-2 *env* gene using SV40 vectors. These experiments are aimed at defining the rev-responsive element in HIV-2 and determining the ability of HIV-1 and HIV-2 rev proteins to cross-complement.

T.C.P.81

ASSAY SYSTEMS FOR HIV REV FUNCTION USING CHIMERIC GENE CONSTRUCTIONS

Lu, Xiaobin*; Prasad, S.; Sangwan,I.; Polisoto,D.; Rekosh, D. and Hammarskjöld, M.-L.; Departments of *Biological Sciences, Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

We have made chimeric constructs containing different regions of the envelope gene linked to either the gene for ß-galactosidase or the EBV EBNA1 protein. For ß-gal, a series of plasmids were created in which ß-gal was fused in frame to the envelope protein leader. 5' to 3' these plasmids contain: the first coding exon of rev, the env leader, ß-gal and different portions of the env gene. Some constructs contain the second coding exon of rev and produce both ß-gal and rev. Mutations in rev cause a decrease in ß-gal activity. Activity is restored when rev is provided in trans.Thus rev-dependence can be conveyed to ß-gal expression and only portions of the env gene are required to see the effect. For EBNA1, the entire open reading frame including the stop codon was fused to a portion of the env gene including the second coding exon for rev. This chimera was inserted into a SV40 vector.The construct produces both an authentic EBNA1 and an EBNA1-rev fusion protein. Both are detectable with EBNA1 specific antiserum.The fusion protein also reacts with a rev-specific antiserum but has no detectable rev activity. It is made because a splice donor near the 3' end of the EBNA1 ORF is used in conjunction with a splice acceptor at the start of the rev coding exon. When active rev is supplied in trans, expression of the authentic EBNA1 protein is favored.Thus rev activity can be measured by quantitation of the two proteins.

T.C.P.82

DIRECT ANALYSIS OF GENETIC DIVERSITY AND EVOLUTION OF HIV IN INFECTED PERSONS USING POLYMERASE CHAIN REACTION (PCR)

Ou, Chin-Yih.; Robbins, K.; Jason, J.; Horsburgh, Jr C.R.; Evatt, B.; Schochetman, G.; et al. Centers for Disease Control. Atlanta, GA. U.S.A.

Objective. To directly determine the genetic diversity and evolution of HIV in the lymphocytes of infected persons using a PCR, cloning and sequencing protocol.
Methods. A primer pair was used to directly amplify HIV sequences from lymphocyte DNA. Amplified DNA (about 320 bp) included a constant domain, C3, and two variable domains, V4 and V5 of the *env* gene. Restriction endonuclease sites were incorporated in the primers to facilitate cloning of the amplified HIV DNA into M13. Sequence determination of individual clones was performed using an automated DNA sequencer.
Results. Using an HIV DNA of known sequence, we estimated an overall error rate attributable to PCR, cloning and sequencing to be 0.24 substitution per 100 bases. Of 24 cloned HIV sequences determined from a hemophilic man, only 2 were identical. In the other 22 clones, multiple base substitutions, deletions (15 bp) and insertions (6 and 24 bp) were observed in V4 and V5. All the deletions and insertions and a majority of the base substitutions occurred in more than two clones. Most base substitutions were clustered and lead to amino acid changes. Insertions arose from duplications in tandem, which appeared to be an important source for HIV diversification. Five of 11 clones from a pre-seroconversion specimen of a homosexual man had identical sequences. The same sequence was present in 6 of 12 clones derived from a post-seroconversion specimen collected 5 mo. later. The other clones differed from the predominant one by 1 to 3 base substitutions.
Conclusion. We have demonstrated that PCR amplification followed by cloning and sequencing is a powerful approach to directly assess the genetic variation and evolution of HIV in infected persons.

T.C.P.83

HUMAN CHROMOSOME 12 IS REQUIRED TO SUPPORT AN ELEVATED LEVEL OF HIV GENE EXPRESSION IN HUMAN-HAMSTER HYBRID CELLS.

Hart, Clyde*; Galphin, J.*; Ou, C.Y.*; Bacheler, L.T.**; Wasmuth, J.***; Petteway, S.R.****; Schochetman G.*. *Centers for Disease Control, Atlanta, GA., USA. **E.I. DuPont Nemours, Wilmington, DE., USA. ***University of California School of Medicine, Irvine, CA., USA. ****SmithKline and French Laboratories, King of Prussia, PA., USA.

Objective. To identify a human chromosome(s) that is required to support an elevated level of HIV *tat*-directed gene expression and virus production.
Methods. A series of human lymphocyte-Chinese hamster ovary cell hybrids with a defined human chromosome content were tested for *tat*-directed *trans*-activation of the HIV-LTR and extracellular virus production. DNA transfection of the cells with a plasmid containing a complete HIV proviral clone was used to assay virus production. *Tat trans*-activation of the LTR was tested by DNA cotransfection of the cells with a plasmid containing an HIV-LTR linked to a chloramphenicol acetyltransferase gene and a plasmid with the HIV *tat* gene under control of a SV40 promoter.
Results. Four of 18 hybrids produced elevated levels of extracellular virus when compared to the CHO parental cell line. These four hybrid clones also had significant increases in LTR-CAT expression in the presence of the *tat* gene. Karyotype analysis of the hybrids revealed a concordance of 94% (17/18) between human chromosome 12 and virus production. In contrast, all other chromosomes had an 11% to 72% concordance with virus production.
Conclusion. Our results indicate that a gene(s) encoded on human chromosome 12 is required for an increase in *tat*-directed *trans*-activation of the HIV-LTR leading to an increase in virus production.

T.C.P.84

EPITOPE MAPPING OF THE HIV-1 GAG REGION BY ANALYSIS OF GAG GENE DELETION FRAGMENTS EXPRESSED IN *E. COLI* DEFINES EIGHT ANTIGENIC DETERMINANTS

Marcus-Sekura, Carol; Woerner, A.; Zhang, P.-F.; Klutch, M.
LDV, DV, Center for Biologics Evaluation and Research, Bethesda, MD, USA.

Objective. To map epitopes on HIV-1 gag proteins to specific protein sequences.
Methods. Portions of the HIV gag gene were cloned into *E. coli* expression vectors and mapped on the genome by sequencing. Clones consisted of two 5' coterminal sets: the first consisting of a clone expressing the carboxyl-terminal 13 aa of p17, all of p24 and p15, and five 3' deletion mutants; and a second set consisting of a clone expressing the carboxyl-terminal portion of p24 and the amino-terminal portion of p15 and a 3' deletion mutant. Partially purified antigens expressed by the 8 clones were used in ELISA with 15 anti-gag monoclonal antibodies (MoAb).
Results. MoAb reacted differentially with the deleted clones depending on the antigen portion expressed. Of twelve potential identifiably different genomic regions predicted from the structure of the clones, 8 different antigenic epitopes were defined: 2 on p17, 4 on p24, and 2 on p15. Four regions did not appear to react with any of the MoAb.
Conclusion. Immune responses to HIV infection include apparent loss of p24 antibodies accompanied by increases in p24 antigen levels with disease progression. Precise definition of the immunodominant epitopes contained in the cloned antigens has potential clinical significance. These cloned antigens are currently being used to evaluate sera from patients at different clinical stages of progression to AIDS.

T.C.P.85 ACTIVE HIV PROTEASE PURIFIED IN A SINGLE STEP FROM *ESCHERICHIA COLI* INCLUSION BODIES

Alfredo G. Tomasselli, J.O. Hui, D.J. Staples, T.K. Sawyer, C-S.C. Tomich*, and R.L. Heinrikson. Biopolymer Chemistry and *Molecular Biology, The Upjohn Company, Kalamazoo, MI, U.S.A.

Recombinant HIV protease, produced as inclusion bodies in *Escherichia coli*, was solubilized with 6M Gu-HCl and purified in a single step by reverse phase HPLC. This procedure yielded a pure, but inactive protein migrating as a single band of M_r = 10,000 in SDS-gel electrophoresis and exhibiting the N-terminal amino acid sequence and amino acid composition expected for the mature protease. The pure inactive protein was lyophilized, dissolved in 8.0 M urea, and refolded to an enzymatically active molecule by diluting the denaturant to 0.8M with 50 mM sodium acetate, pH 5.5, containing 10% glycerol, 5% ethylene glycol, 0.2% Nodinet P40 and 2.5 mM DTT. The final enzyme concentration was 0.5-1.0 mg/ml. About 0.2 mg of active protease per liter *E. coli* cell culture is obtained quickly by the above technique. Freeze-thawing of the enzyme solution did not lead to a significant loss of activity. The enzyme was active as a dimer and cleaved the bond between the Tyr and Pro of the octapeptide V–S–Q–N–Y–P–I–V with a pH optimum of 6.1. Lineweaver-Burk plots showed inhibition by the octapeptide substrate at concentrations higher than 3.6 mM. V_{max} was 1.5 µmol x min^{-1} x mg^{-1} and K_M was 1.7 mM. In keeping with other aspartyl proteases, the HIV enzyme is inhibited by pepstatin with a K_i = 0.4 µM.

T.C.P.86 ANALYSIS OF THE EXPRESSION OF HIV-1 ANTIGENS IN THE BACULOVIRUS SYSTEM.

Parker, D.; Weller, R.; Ahern, S. and Rodgers, B.
Diagnostics R&D, Wellcome Research Labs., Beckenham, Kent, U.K.

Objectives. To investigate the effect of the signal peptide and membrane anchorage domain on the expression and stability of HIV-1 envelope in insect cells and to express the antigenically important domains of the HIV-1 gag and env genes as a fusion protein.
Methods. A transfer vector containing the appropriately engineered HIV-1 sequences was used to produce recombinant baculoviruses which expressed the particular antigens under the control of the viral polyhedrin promoter. The expressed proteins were analysed by PAGE, ELISA and immunoblotting.
Results. The HIV-1 env gene can be expressed in insect cells as a glycoprotein of 150kD (gp150) but is not cleaved to gp120 and gp41. The protein is expressed to reasonable levels (>1mg/l) and remains intracellular. The signal sequence does not appear to lead to secretion of the protein from the insect cells. When the anchor sequence is removed and replaced by sequence from the transfer vector the resulting protein is less stable. A fusion of p24gag and the immunodominant region of gp41env could be expressed in this system as a stable protein which is apparently glycosylated. All the recombinant proteins were reactive with anti-HIV-1 positive sera in both ELISA and Western blots.
Conclusions. The baculovirus system is useful for expressing HIV-1 proteins because it can carry out post-translational modifications such as glycosylation. However not all processing signals will work in this system. The expressed antigens are useful diagnostic reagents and potential vaccine components.

T.C.P.87 TRANSLATIONAL EFFECTS OF THE 5' UNTRANSLATED REGION OF HIV-1 IN VIVO: REGULATION BY TAT.

Parkin, Neil*, Rosen, C.**, and Sonenberg, N.*
*McGill University, Dept. of Biochemistry, Montreal, Quebec, Canada, and **Dept. of Molecular Oncology, Roche Institute of Molecular Biology, Nutley, NJ, USA.

Objective. To investigate the possibility of translational repression of mRNAs containing the 5' untranslated region (UTR) of HIV-1, and the effect of tat expression in vivo.
Methods. CHO and HeLa cell lines expressing the CAT reporter gene containing portions of the 5' UTR of HIV-1 (TARCAT and derivatives) were established by cotransfection with pSV2neo and selection in G418. Translational efficiencies of CAT mRNAs were assessed by comparing the CAT activity with the steady state level of cytoplasmic CAT RNA, measured using a sensitive RNAase protection assay. The tat protein was delivered by co-transfecting the TARCAT cell lines with tat expression vectors and pSV2hygrB, and selection in hygromycin B.
Results. TARCAT mRNA containing the first 110 nucleotides from the HIV-1 5' UTR was found to have 10-fold reduced translational efficiency in CHO cells compared to CAT mRNA from pSV2CAT. Results will be presented to show the importance of stable stem-loop structures in the 5' UTR for this effect. Expression of tat led to large increases in CAT protein levels, but relatively small increases in CAT cytoplasmic RNA. The trans-activation response is therefore partially at the translational level in these cells. The effect of tat on the observed 10-fold translational inhibition by the 5' UTR will also be analyzed.
Conclusions. The 5' UTR of HIV-1 can inhibit the translation of its mRNAs in vivo. The expression of tat leads to an increase in translational efficiency of these mRNAs in this system, where both the tat gene and the CAT reporter gene are stably integrated in the cellular DNA, similar to the situation in cells infected with HIV.

T.C.P.88 FAILURE OF INTERFERON α MESSENGER RNA SYNTHESIS IN PBMC OF HIV-1 INFECTED PATIENTS AT LATE STAGES

Voth R., Rossol S., Klein K., Brunner S., Jochum C., Müller W.E.G.*, Meyer zum Büschenfelde K.H. and Hess G.
I. Med. Klinik und Poliklinik und *Institut für Physiolog. Chemie, Johannes Gutenberg Universität Mainz, FRG.

OBJECTIVE: To determine the mechanisms responsible for absent interferon α production in appropriately stimulated PBMC of HIV-1 infected patients at late stages.
METHODS: PBMC of 68 HIV infected patients at various stages were isolated by Ficoll-Paques Sedimentation. After overnight stimulation with 5×10^4 PFU of Vesicular Stomatitis Virus, RNA was isolated and tested for interferon α messenger RNA content by using Northern Blot Analysis with a specific cDNA probe for the interferon α gene. Simultaneously interferon α secretion into the supernatants of stimulated cells was measured by a highly specific Enzyme Immuno Assay.
RESULTS: Release of high doses of interferon α by PBMC of patients at stage II paralled with the production of mRNA coding for the α interferon gene. However patients who failed to secrete any interferon α into the supernatant showed abundance of α interferon messenger RNA as determined by Northern Blot Analysis. GAPDH cDNA which was used as a positive control revealed in unchanged signals irrespective of patients were able to produce high amounts or no IFN α gene transcripts, indicating that cells were intact.
CONCLUSIONS: Our data provide evidence that HIV-1 infection can modulate the production of interferon α in peripheral blood cells on the transcriptional level.

T.C.P.89 ACIDIC RESIDUES WITHIN THE AMINO TERMINAL REGION OF HIV-1 TAT IS CRITICAL FOR TRANSACTIVATION

Rappaport, Jay F., Lee, S.-J., Khalili, K., and Wong-Staal, F. Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Maryland 20892 USA.

Objectives: Eukaryotic transacting factors often contain, in addition to a nucleic acid binding domain, a separate transacting domain (Ptashne, Nature 335: 683, 1988). These regions are acidic and often amphipathic. The amino terminus of HIV-1 is acidic and secondary structural analysis of this region predicts an amphipathic helix. We propose that this region is important for tat function.
Methods: A tat encoding cDNA was subcloned into m13 phage and site directed mutagenesis was performed. Mutant cDNAs were subcloned into the expression vector pSV, and analyzed for the capability to transactivate the HIV-1 LTR in transient transfection assay.
Results: Conservative changes (acidic to acidic) were well tolerated, while acid to neutral and acidic to basic changes dramatically reduced tat activity. The relative importance of each of the three acid residues correlates with proximity to the amino terminus. Substitution of the entire domain with heterologous sequences partially restores activity.
Conclusion: The data suggest that the acidity, as well as the structure of the amino terminal region, are critical for transactivation.

T.C.P.90 CD4(81-92) PEPTIDE ANALOGS BLOCK HIV INFECTION, HIV-INDUCED CYTOPATHICITY, AND POST-INFECTION VIRAL TRANSMISSION IN VITRO, AT MICROMOLAR CONCENTRATIONS.

Eiden, Lee*; Hwang, K.**; Nara, P.***; Padgett, M.*; Rausch, D.* and Lifson, J.**.
*LCB, NIMH, Bethesda, MD, USA, **Divs. Immunology & Medicinal Biochemistry, Genelabs Incorporated, Redwood City, CA, USA; ***LTCB, NCI-FCRF, Frederick, MD, USA.

Objective. To determine structural requirements for CD4(81-92)-based antireceptor peptide blockade of HIV-1 infection, HIV-1-induced cytopathicity, and cell-mediated HIV-1 transmission in vitro.
Methods. Peptides synthesized by FMOC chemistry, with benzyl (b) or alkyl (alk) derivatization at specific amino acid residues. Doses given for 100% inhibition of HIV-induced cell *fusion* (Lifson et al., Science 232, 1123, 1986), >50% inhibition of HIV-1 (HTLV-IIIB) *infection* of CEM-SS cells quantitated by a syncytial-forming microassay (Nara et al., AIDS Res. Hum. Retrovir. 3, 283, 1987), and >50% inhibition of cell-mediated viral *transmission* measured by formation of syncytia between HIV-1(HTLV-IIIB)-infected cells incubated 120 hours post-inoculation (peptide present during the final 72 hours of incubation), and fresh uninfected CEM-SS cells (Nara and Fischinger, Nature 332, 469, 1988).

Results.	Peptide	Fusion	Infection	Transmission
	TbYICbEbVEDQKEE	63 µM	63 µM	125 µM
	TbYICbEbVEDQKEEalk	16 µM	10 µM	not detn'd
	TbYICbEVEbDQKEE	>500 µM	>250 µM	>250 µM
	KEEICbEbVEDQTbY	>500 µM	>250 µM	>250 µM

Conclusions. Derivatives of CD4(81-92) potently inhibited HIV-1 infection and HIV-1-induced cytopathicity (fusion). Antireceptor peptide potency is apparently dependent on both conformation, since only benzylation on specific residues afforded active peptide, and sequence, since a sequence-altered peptide of identical composition was without antiviral activity. In addition, CD4(81-92)-based antireceptor peptides appear to possess a 'virostatic' activity inasmuch as cell-mediated viral transmission, measured by formation of infectious cell centers following treatment of HIV-infected CEM-SS cells with peptide for 72 hours, beginning 48 hours post-infection, is inhibited by such treatment. This unique property of small, CD4-based peptides may recommend them for therapeutic consideration.

T.C.P.91 PROMOTOR ACTIVITY OF 5' LTR REGION OF A HIGHLY CYTOPATHIC STRAIN OF HIV-1

I. HIRSCH, J. SIRE, V. ZACHAR, B. SPIRE and J.C. CHERMANN.

Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cedex 9, FRANCE

In order to correlate the high cytopathic properties of HIV-NDK strain with genetic variation, the virus was cloned and sequenced. The cloned DNA was biological active as revealed by transfection into CD4 cells. One of the major differences in the alignement of nucleotides sequences of HIV-NDK and HIV-BRU prototype virus was localised in the 5' part of the LTR U3 -region. In a set of cotransfection experiments the effect of transactivating (TAT) gene product on promotor activity localised in the 5' LTR region of both, HIV-BRU and NDK viruses was compared in CAT assay. It was found that promotor activity of 5' LTR of HIV-NDK was several times higher than that of HIV-BRU prototype even without a stimulatory effect of the TAT gene product. To approach the effect of LTR region on cytopathogenecity of HIV more directly, the recombinant DNA molecule bearing HIV-NDK-LTR regions and rest of the genome derived from BRU prototype was constructed. The DNA was transfected into the cells and the virus obtained ; its properties are under investigation.

T.C.P.92 DETECTION AND SEQUENCING OF INDIVIDUAL MOLECULES OF HIV DNA AMPLIFIED BY A MODIFIED PCR

Simmonds, Peter; Balfe, P.B.; Leigh-Brown, A.J. and BISHOP, J.O.
Department of Genetics, University of Edinburgh, Scotland, United Kingdom

The sensitivity of polymerase chain reaction (PCR) has been enhanced by the use of nested primers, which allowed the detection of individual molecules of HIV DNA from patient samples. Amplification of DNA involves a first reaction with a pair of HIV-specific primers, transfer of a small proportion of the product to a second tube containing primers that lie within the first pair, and a further round of amplification. Dilution studies of plasmid derived HIV sequences showed that amplification of single molecules of target sequence with different sets of primers was reliable even with primer spacings as wide as 500 base pairs. The specificity of the test was assured by the uniformly negative results obtained from a panel of seronegative blood donors with two sets of nested primers. Limit dilutions of DNA prepared from buffy coat coat cells of HIV-infected haemophiliacs allowed the isolation, amplification and sequencing of individual molecules. This method has many advantages over previously described methods of sequencing HIV by the PCR method: 1) Amplification of the target sequence takes place in the absence of competition from others that replicate faster, or match the primers better. 2) It is less prone to sequencing errors. 3) It allows the amplification of several regions from the same HIV genome.

T.C.P.93 BINDING OF THE HIV-1 TAT PROTEIN TO TAR SEQUENCES IN VITRO.

Dingwall, C.; Ernberg, I.; Heaphy, S.; Skinner, M. A.; Gait, M. J. & Karn, J.
MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 2QH, U.K.

Objective. To investigate the binding *in vitro* of HIV tat protein and cellular factors to TAR sequences.

Methods. A synthetic *tat* gene has been expressed both in an *E. coli* expression system and in a number of eukaryotic cell lines. The binding of expressed tat protein to nucleic acid representing the TAR sequence has been investigated *in vitro* using gel retardation assays.

Results. The tat protein produced from both the *E. coli* and from the eukaryotic expression systems has been shown to be biologically acive. The binding of tat, synthesised in *E. coli*, to TAR nucleic acid has been examined both in the presence and absence of host cellular proteins. Binding of tat expressed in eukaryotic cells gives a different pattern, suggesting that host proteins interact with the tat/TAR complex. The specificity of binding has been examined using a number of different nucleic acids, including mutant TAR sequences.

Conclusion. Direct interactions between tat protein and TAR sequences are involved in *trans*-activation.

T.C.P.94 CHARACTERIZATION OF THE INFECTIVITY OF HIV PROVIRUSES CONTAINING MUTATIONS IN LTR REGULATORY SEQUENCES

Leonard, J.M.*; Parrott, C.M.*; Buckler-White, A.**; Martin, M.A.* and Rabson, A.B.*
*NIAID, NIH, Bethesda,Md. USA; **Georgetown University, Washington, D.C. USA.

Objective. To characterize the biological effects of mutations in the cis-acting regulatory sequences of the HIV LTR.
Methods. Oligonucleotide-directed, site-specific mutagenesis was employed to generate mutations in the regulatory sequences in the HIV-1 LTR. Mutated LTRs were introduced into an infectious molecular clone of HIV. Mutant proviruses were assayed for infectivity and growth in human T cells. Mutant LTRs were also tested for transcriptional activity by transfection of LTR-CAT plasmids.
Results. An HIV provirus containing a deletion of both NF-κB binding sites yielded infectious virus that replicated efficiently in MT 4 cells. Mutants defective in Sp1 binding at the 5' Sp1 site (site III) were also capable of efficient growth; proviruses with additional mutations in the Sp1 binding sites varied in their ability to produce infectious virus. In CAT assays, the mutant LTR deleted in the NF-κB sites exhibited decreased basal activity compared to the wild-type LTR, but was strongly responsive to *tat* transactivation. The effects on viral infectivity of changes in other parts of the LTR will also be discussed.
Conclusions. The NF-κB binding sites were not essential for HIV replication in MT 4 cells. Other mutations affecting the Sp1 binding sites also did not interfere with the ability to produce infectious virus. Thus HIV can replicate even when alterations are introduced into the wild-type enhancer and promoter elements.

T.C.P.95 ANALYSIS OF VPX FUNCTION IN HIV-2 INFECTED CELLS

Lee Ratner, W Hu, and M Vander Heyden. Departments of Medicine and Microbiology & Immunology. Washington University, St. Louis, Mo., USA

Objective: A novel gene, designated vpx, is present in the genomes of HIV-2, and SIVs, but not HIV-1. Our goal was to define the role of VPX in HIV-2 replication and cytopathicity.
Methods: A functional proviral clone of HIV-2, SE, was made and used to construct site directed mutants which only eliminate the AUG initiator codon of vpx (MX1), which convert codon 22 to a termination codon (MX22), or which simultaneously eliminate the first and second AUG codons and frameshift the gene introducing a termination codon at position 70 (MX1+62).
Results: Transfection of SE, MX1, MX22, and MX1+62 into COS-1 cells gave rise to equivalent amounts of virus, which could be passaged in H9 or CEM cells, or in peripheral blood lymphocytes or monocytes with equivalent efficiency. Furthermore, the vpx mutants demonstrate similar cytopathic effects as did SE. Hybridization data with DNA from the infected cells demonstrated the presence of the mutations in each of the MX infected cell lines, and equivalent levels of viral DNA and RNA sequences in SE and MX infected cell lines. Immunoprecipitation analysis demonstrated a 16 kd protein in cells infected with SE virus as well as the virus particles, but not in cells infected with the MX viruses or the particles themselves. Equivalent levels of GAG and ENV proteins were demonstrated in all infected cells and virion preparations.
Conclusions: These data suggest that VPX is dispensable for virus replication and cytopathicity. Further analysis of the vpx mutants is underway to define VPX activity in animal model systems.

T.C.P.96 HIGHLY EFFICIENT NEUTRALIZATION OF HIV WITH RECOMBINANT CD4-IMMUNOGLOBULIN MOLECULES

André Traunecker, Josef Schneider*, Hansruedi Kiefer and Klaus Karjalainen. Basel Institute for Immunology, Basel, Switzerland, * Central Research Units, F. Hoffmann-La Roche & Co. Ltd, Basel, Switzerland.

It is well established that the human immunodeficiency virus type I (HIV-1) exploits the cell surface CD4 molecule to initiate the infection which can eventually lead to acquired immune deficiency syndrome (AIDS). We and others have taken advantage of this specific interaction between the HIV-1 envelope protein gp120 and CD4 and have shown that soluble CD4 molecules can inhibit HIV infectivity in vitro. However, application of these observations in vivo might require more potent reagents. Here we describe the generation of highly effective molecules which combine the specificity of CD4 and the effector functions of different immunoglobulin (Ig) subclasses. We show that pentameric forms of chimeric CD4-immunoglobulin molecules are about 1000 fold more active than their dimeric counterparts in syncytium inhibition assays.

T.C.P.97

PACKAGING AND TRANSFER OF A MARKER GENE BY HIV VECTOR PARTICLES

Clavel,Francois*, Danos,O**, and Alizon,M**. *Laboratory of Molecular Microbiology, NIAID, NIH, Bethesda, MD, USA. **Whitehead Institute, Cambridge, MA, USA

Objective. To package foreign sequences in HIV particles and transfer them to HIV-sensitive target cells.
Methods and Results. Several HIV vectors were generated by introducing a selectable resistance gene (HIS) into the HIV genome. Cell lines were then established that could express these genomes, and package them into HIV particles following the transfection of HIV helper sequences. After infection of CD4+ cells with such particles and selection, we were able to demonstrate the successful transfer and integration of HIV genomes carrying the marker resistance gene. Different constructs were compared for their efficiency to transfer the marker gene, in order to delineate the cis-acting sequences required for the complete packaging, reverse transcription, and integration of the HIV genetic material.
Conclusion. We demonstrated the packaging and successful transfer of a genetic marker through HIV particles. HIV vectors will be valuable tools to study the HIV replicative cycle, and to specifically target sequences to HIV-sensitive cells.

T.C.P.98

INTERACTION OF HIV WITH INTERFERON REGULATED, ANTIVIRAL ENZYMES.

Silverman R.H[1]; Sengupta D.N[1]; Dion M[2]; and Williams B.R.G[2].
[1]Department of Pathology, Uniformed Services University of the Health Sciences, Bethesda MD USA and [2]Division of Infectious Diseases, Research Institute Hospital for Sick Children, Toronto, Canada.

The interferon (IFN) system is activated in AIDS and high levels of circulating acid labile IFN-alpha often accompany disease development. Although HIV replication in cell culture can be inhibited by IFN, the virus appears to have evolved a mechanism of escaping the anitviral activity of the IFN usually present in AIDS. We have investigated the activation of IFN-induced enzymes by HIV. The 5' leader of HIV-1 mRNA contains two double-stranded stems of about 17 and 23 base pairs in length. HIV-leader RNA of 232 nucleotides was produced from a plasmid containing HIV-1 LTR sequences located 3' to an SP6 promoter. The RNA product was purified and analysed to ensure the absence of aberent transcripts. This HIV-1 leader RNA was shown to activate both dsRNA-dependent protein kinase and 2-5A synthetase in an extract of IFN-treated HeLa cells. Furthermore, these enzymes were immobilized and activated on an affinity resin consisting of HIV-1 leader RNA covalently attached to finely divided cellulose. In HIV-infected cell cultures however, although IFN was able to induce 2-5A synthetase levels, no evidence for endogenous activation of the 2-5A pathway was obtained. It remains possible therefore, that viral or cellular factors in HIV-infected cells interfere with the activation of IFN-induced enzymes and contribute to viral latency.

T.C.P.99

HIV-1 REPLICATES IN HUMAN SPERM MITOCHONDRIA OF HIV-SEROPOSITIVE INDIVIDUALS

Bagasra, Omar ; Freund, M. ; Candolucci, D.*** ; Heine B.; Weidmann, J. U. of Medicine and Dentistry NJ, School of Osteopathic Med. Depts. of Microbiology , Ob/Gyn and Medicine , Camden, New Jersey, USA.

Objective. To determine the replication site(s) of HIV-1 in the sperm of HIV-seropositive individuals.
Methods. Sperm specimens from three AIDS/ARC individuals were scrutinized for the localization of HIV-1 by electron microscopy (EM), HIV-specific mAbs-immunogold EM, and in situ hybridization using HIV-specific DNA probes.
Results. (1)Analysis of sperm by the DNA hybridization procedure revealed that over 90% of sperm which were positive for HIV by in situ hybridization, had their midpieces enlarged (4-10 times greater than normal controls). (2) HIV-DNA probes were more concentrated at the midpiece than in the sperm heads, in terms of relative intensity of staining. (3)Immunogold staining showed aggregation of gold particles in association with mitochondria. (4) Presence of HIV-like particles in many mitochondrial organelles was noted. (5) Some mitochondria resembled pods with HIV-like particles "bursting out" of them like spores.
Conclusion. These observations suggest that HIV in sperm may be replicating in the mitochondria, using mitochondrial DNA as a replicating device. It is possible that in human sperm where there is condensation and tight packaging of haploid DNA in the nucleus, relative to that in somatic cells, the random integration of the HIV proviral DNA into the nuclear-DNA might be difficult and mitochondrial-DNA may be an easier target. On the other hand, if cellular mitochondria is a global target for HIV, then different therapeutic approaches might be adopted.

T.C.P.100

TRANSMISSION OF SIV_{MND} IN A SEMI-FREE RANGE BREEDING COLONY OF MANDRILLS IN GABON.

Peeters, Martine*; Delaporte, E.*,**; Honoré, C.* Cooper, R.W.*; Bussi, P.*; Dixson, A.L.*
* Centre International de Recherches Médicales, BP 769, Franceville, Gabon;

Objective. To study the transmission (vertical and horizontal) of a simian immunodeficiency virus from mandrills in a colony of mandrills.
Methods. A total of 33 mandrills were tested. 16 of them were wild caught animals. Antibodies were detected by a radio-immunoprecipitation assay using ^{35}S-methionine labeled SIV_{MND} virus. Virus was isolated from peripheral blood lymphocytes cocultivated with MOLT-4 cells.
Results. Two of the 16 wild-caught animals (1 1) were positive since their arrival at the primate centre (1979 and 1983 respectively). A virus was isolated (Tsujimoto) and showed antibodies to the SIV_{MND} glycoproteins only. In 1988, two new animals showed antibodies to the SIV_{MND} envelope proteins and also to the core proteins. One of these animals was a wild-caught male that was seronegative at his arrival to our centre. The other one is the second offspring of the already known positive female. Since her arrival in 1983 at CIRMF, she was pregant twice, one animal was born in 1985 (seronegative 1, 2 and 3 years respectively after birth) and one in 1987. This animal showed antibodies one year after delivery and a virus was isolated from his peripheral blood lymphocytes.
Conclusion. SIV_{MND} appears to be transmitted from mother to child in a semi-free-range breeding mandrill colony. A seroconversion with appearance of antibodies to p27was observed, and a virus was isolated.

T.C.P.101

A COLOROMETRIC ASSAY FOR TRANSACTIVATION OF THE HIV-1 LTR

Edward D. Blair*, M.G. Davis** and C.R. Roberts*.
Wellcome Research Labs, *Beckenham, UK, and **RTP, N. Carolina, USA.

Objective: To develop a simple, rapid and sensitive assay for the activation of the HIV-1 LTR by TAT and by heterologous factors.
Methods: Stable cell lines containing multiple integrated copies of the HIV-1 LTR (-122/+80) linked to the lacZ gene of E.coli were prepared by co-selection for pSV2neo-mediated G418 resistance.
Results: HIV-1 LTR lacZ was transactivated equally well or better in rabbit skin (epithlial-like) cells than in other cell types (HeLa, CV-1, Flow 4000, etc.), by cotransfection with genomic TAT (gTAT) expressing plasmids (pCMVTAT, pRSVTAT, pRSVTAT/REV), and so stable RS/LTR lacZ cell lines were prepared to mimic the structure of the integrated provirus in latently infected cells. Three of ten independent clones responded to gTAT, and one clone was used to show that D-penicillamine was not an effective inhibitor of TAT transactivation at concentrations up to 100ug/ml. The efficacy of anti-sense phoshorothioate oligonucleotides against TAT are currently under examination in these lines. The same lines also express high levels of B-galactosidase in response to HSV-1 infection, and transactivation by IE gene products from herpes group viruses is under examination.
Conclusions: Selection of the appropriate substrate for B-galactosidase will permit detection and measurement of LTR transactivation (MUG;ONPG) and also detection of infectious centres (X-gal) in these cell lines. Therefore, molecular aspects of HIV reactivation and autologous gene regulation can be readily analysed.

T.C.P.102

HIV-I REV INDUCED MODULATION OF NEF PROTEIN UNDERLIES REGULATION OF VIRAL REPLICATION

Ahmad, Nafees, Maitra, R. K. and Venkatesan, S.
Laboratory of Molecular Microbiology, NIAID, National Institutes of Health, Bethesda, MD 20892, U.S.A.

Objective: To study the potential functional roles of HIV-1 Rev and Nef proteins that might underlie the regulation of viral replication.
Methods: A rev defective proviral DNA was constructed from infectious HIV-I proviral clone pNL432. The Rev and Nef were supplied in trans by cotransfection of cDNA plasmids under the control of various promoters.
Results: The phenotype of rev mutant provirus was distinguished by accumulation of Nef and reduced Tat function. During transcomplementation of the rev mutant by rev cDNA, there was a decrease of both the steady state levels and rates of synthesis of Nef accompanied by enhanced viral structural proteins. Nef protein, a transcriptional repressor (Ahmad and Venkatesan, Science, 241, 1481-1485, 1988), moderated the Rev induced transactivation in a dose dependent manner. Neither the replication of standard provirus nor the repression induced by nef cDNA was modulated by cotransfection of rev cDNA.
Conclusion: The ability of Rev to modulate Nef expression from the provirus and hence relieve the inhibition of LTR transcription reveals a delicate balance of functions of these two proteins that might underlie the switch between latency and reactivation.

T.C.P.103 HIV-1 TAT FUNCTIONS IN XENOPUS OOCYTES IN THE PRESENCE OF TRANSCRIPTION INHIBITORS

Braddock, Martin*; Chambers, A.*; Wilson W.*; Adams, S.E.**; et al; Kingsman, A.J.*,** and Kingsman, S.M.*
*Department of Biochemistry, South Parks Road, Oxford, OX1 3QU, U K
**British Biotechnology Ltd., Watlington Road, Cowley, Oxford

Objective. To determine the level of gene expression at which the HIV-1 TAT protein exerts it's effect.
Methods. We have developed a novel method for purifying biologically active TAT protein. TAT activity was determined by monitoring the expression of an HIV-LTR CAT reporter plasmid in the presence and absence of transcription inhibitors micro-injected into Xenopus oocytes.
Results. We show the TAT stimulates LTR- directed expression and that this stimulation in Xenopus oocytes, as in the virus, is dependent on the presence of the TAR sequence. Furthermore TAT activation of LTR-CAT functions independently of alpha-amanitin, 3'-deoxyadenosine and actinomycin D. The former inhibits transcription initiation and the latter two transcription elongation.
Conclusion. These data strongly suggest a post-transcriptional mode of action of TAT on the HIV-1 LTR in Xenopus oocytes.

T.C.P.104 GENES IN THE 3' END OF HIV CONTROL HIV REPLICATION AND CYTOPATHOLOGY

Cheng-Mayer, Cecilia, Quiroga, M.*, Dina, D.*, Levy, J.A.
Cancer Research Institute, University of California, San Francisco, CA, *Chiron Corporation, Emeryville, CA, USA.

Objective: To map the HIV gene(s) that control different biologic properties.
Method: HIV isolates with different biologic properties were molecularly cloned. Biologically active recombinant viruses were generated by DNA manipulations and transfections. Properties of recombinant viruses were examined by host range studies to correlate structure/function relationship of HIV.
Results: A macrophage tropic HIV-1-SF162 has been molecularly cloned and determined to be biologically active. Unlike HIV-1-SF2, HIV-1-SF162 does not replicate in T cell lines, is not cytopathic, does not down-modulate the CD4 receptor molecule on CD4 lymphocytes, but replicates efficiently in primary macrophages. Genomic recombinants have been generated between HIV-1-SF2 and HIV-1-SF162. Studies with recombinant viruses have shown that the 3' end of the HIV genome controls most of the biologic differences (Table 1). Fine structure mapping may identify the specific genes (env, nef or regulatory elements) that control the various biologic properties of HIV.

Physical Mapping of HIV Functions

HIV 1	HIV 2	Source	Replication in T cell lines	Replication in macro...	Cytopathology	CD4 down modulation
Parentals						
SF2	SF2	PMC	+	-	++	+
SF162	SF162	CSF	-	+	-	-
Recombinants						
SF2	SF162		-	+	-	-
SF162	SF2		+	-	++	+

Conclusion: Studies with recombinant viruses will allow the identification of genes that determine the pathogenic properties of HIV.

T.C.P.105 MOLECULAR CLONING AND SEQUENCING OF A NEW HIV2 ISOLATE ($\text{HIV2}_{\text{CAM2}}$)

Tristem, Michael*; Karpas, A.* and Hill, F.*
*Department of Haematology, University of Cambridge Clinical School, Hills Road, Cambridge CB2 2QL, England.

Objective. Cloning and sequencing of a new HIV2 isolate. Comparison of the genetic variability of HIV2 isolates.
Methods. Peripheral blood mononuclear cells from a Guinea-Bissau patient infected with HIV2 was cocultivated with the Karpas 45 T-cell line. A genomic library was constructed from the infected cell line. Restriction maps of clones hybridizing to a pROD probe were constructed. Nucleotide sequence determination of one clone which appeared to be full length is in progress.
Results. Restriction mapping of the full length clone shows difference in 7 out of 22 sites when compared to the prototype clone ROD. To date sequencing of the proviral LTR, gag and pol regions shows approximately 10% divergence from ROD.
Conclusion. These results indicate that $\text{HIV2}_{\text{CAM2}}$ is distinct from other HIV2 isolates. The full sequence and biological properties will be presented.

T.C.P.106 STABLE EXPRESSION AND SECRETION OF RECOMBINANT HIV 1 ENVELOPE PROTEIN IN DROSOPHILA SCHNEIDER CELLS.

H.JOHANSEN, J.CULP, S.MAI, B.VICKROY, B.HELLMIG, M.CHAIKEN, D.MOORE, S.COMER, B.WILSON, P.WARD, M.OKA AND M.ROSENBERG.
Biopharmaceutical Research and Development,Smith Kline & French Laboratories,P.O.Box 1539,King of Prussia,Pa 19406-0939 USA.

An HIV 1 gp120 envelope protein encoding all but the amino terminal 32 residues was expressed and secreted using a Drosophila cell continous culture system. The gp120 gene was incorporated into an expression vector behind the inducible Drosophila metallothionein promoter and was stably introduced into Drosophila cells by co-transfection with a vector encoding the hygromycin B phosphotransferase gene. Stable cell lines containing high copy number of the gp120 transcription unit were obtained in a single transfection-selection event using hygromycin B selection. The resistant cells expressed up to 5 mg/L of gp120 in response to metal induction. The protein was secreted into the medium and was of the expected size for a fully glycosylated protein (110 Kd). Isolation of the protein from the medium was by affinity chromatography after which concentration and identity were confirmed by amino acid composition and N terminal analysis. We have shown that the Drosophila produced gp120 is able to inhibit syncytium formation in HIV-infected H9 cells and that the affinity of the Drosophila produced gp120 for the T4 receptor is identical to that of viral derived gp120 using scatchard analysis assay.

T.C.P.107 POSSIBLE MODE OF INSERTION INTO A LIPID BILAYER OF N-TERMINAL FUSOGENIC SEGMENT OF VIRAL ENVELOPE PROTEINS.

Brasseur R.;Burny A.;Martin I.;Vandenbranden M.; Ruysschaert JM. Lab. Chim.-Phys. des macromol. aux interfaces;Univers. de Bruxelles ;Belgique.

Objective:Analysis of the envelope fusion protein of 45 viruses.
Methods:The complete amino-acid sequence of the fusion protein of 45 viruses has been analyzed in terms of hydrophobicity and hydrophobicity moment by the Eisenberg procedure.We have focused our analysis on the conformational properties of the N-terminal peptide segment of these fusion proteins and their orientation into the lipid bilayer.
Results:For all proteins analysed, the N-terminus segment is characterized by a high hydrophobicity and a low hydrophobic moment.Next to this transmembrane peptide,we identified a "receptor-like" domain,characterized by a sequence of amino acids with a high hydrophobic moment.According to Garnier prediction,the 45 N-terminus peptides adopt an α-helical structure.These helical segments are obliquely oriented in the lipid bilayer with respect to the lipid-water interface:the angle varying from 45° to 65°.We assumed that the distribution of the hydrophobic and hydrophilic amino acids along the helix axis is responsible for the oblique orientation of the peptide into the lipid bilayer and the fusogenic properties of the protein.
Conclusion:The unusual peptides orientation is expected to induce the disorganization of the surrounding lipids and the formation of inverted micellar structures which has been suggested as one of the initial events in the virus/cell fusion.

T.C.P.108 CHARACTERIZATION OF RECOMBINANT HIV REVERSE TRANSCRIPTASE: PURIFICATION OF HOMOGENEOUS, STABLE P66 BY NATIVE/DENATURATION PROTOCOLS.

Thomas J. McQuade, David P. Brunner, Martin Deibel, and W. Gary Tarpley. Divisions of Cancer and Infectious Diseases Research, Bioprocess Research and Development, and Biopolymer Chemistry, The Upjohn Company, Kalamazoo, Michigan, U.S.A.

We engineered a prokaryotic expression vector (pTM-4) encoding the HIV reverse transcriptase under the control of the strong, regulated E. coli tac promoter. Under induction conditions, E. coli JM109 carrying pTM-4 synthesized RT (p66) at about 10% of the total cell protein. We grew this strain in stirred-tank fermentations at the 200-liter scale and purified p66 by native protocols to apparent homogeneity; p66 was not stable and was processed to p51 until p66/p51 were in an approximately 1/1 ratio. Preparations of p66/p51 heterodimers consistently exhibited higher enzymatic activities (3- to 5-fold) than preparations of p66. Chromatographic analyses indicated that preparations of p66/p51 contained extensive microheterogeneity. We also purified p66 by a combination of native/denaturing protocols. Under these conditions p66 was completely denatured with 8M guanidine HCl, purified, and then refolded to native enzymatic conformation. Refolded p66 was not readily processed to p51 or other species. These data suggest that denaturation followed by subsequent purification of p66 resulted in the inactivation and/or separation of E. coli proteases responsible for much of the heterogeneity found in p66 samples. These protocols may be useful in preparing p66 suitable for structural analyses.

T.C.P.109

AN HIV1 PEPTIDE LIBRARY EXPRESSED IN YEAST REVEALS NEW CONTINUOUS EPITOPES.

Madaule, Pascal, Gairin, J.E. and Rossier, J.
CNRS, LPN, 91198 Gif-sur-Yvette CEDEX, FRANCE

Aim. Determination of continuous epitopes relies mostly on chemically synthetic peptides and computer models. However, such an approach may be unsatisfactory due to an inappropriate choice of the sequences synthesised or the limitations of chemistry. We developed an efficient and inexpensive method for the identification of continuous epitopes, even those unpredicted or post-translationally modified.

Methods. A random library of small fragments (50-150 bp) of HIV1 DNA was expressed in *Saccharomyces cerevisiae* with a *new* expression-secretion vector, pSE-X, derived from MFα1. Random fragments obtained by partial DNAse I digest of HIV1 proviral DNA were inserted in pSE-X and a library (4.10^4 clones) was then constructed and screened.

Results. Monoclonal antibodies (directed against p18, p25, gp110 and gp41) and sera from HIV1 infected individuals were used to screen the library. All the monoclonal antibodies used revealed the presence in the library of antigenic determinants, thus validating our expression system. Eight epitopes of HIV1 were characterized, three not previously described, one in the endonuclease, one near the C-terminal region of the gp41 and one in the p25. Immunogenicity of several recombinant peptides is currently analysed on animal models.

T.C.P.110

EFFECT OF HYDROCORTISONE ON THE REPLICATION OF HIV-1 IN DIFFERENT CELL TYPES.

Soudeyns, Hugo; Schneider, V.; Geleziunas, R.; Shyamala, G.; and Wainberg, M.A.
Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, Montreal, Quebec, Canada.

It is well-known that glucocorticoid hormones can regulate either positively or negatively the replication of several retroviruses. In patients with AIDS the plasma hydrocortisone (HC) level is increased between 50 to 70% over that found in normal control subjects. Therefore, towards identifying the relative importance of endogenous glucocorticoid on the replication of HIV in AIDS patients, we examined the effect of HC on HIV replication in a variety of susceptible cell lines, and for the presence of glucocorticoid receptors (GR). The cell lines were infected with the HTLV-III_B strain of HIV-1 at various multiplicities of infection, and grown in RPMI medium containing 10% fetal calf serum and HC ranging in concentrations from 20 μM to 100 μM. The viral activity was estimated by reverse transcriptase assay, and by ELISA. GR levels were estimated by analyzing cell extracts for specific binding of ^{3}H-dexamethasone. HC stimulated HIV production in H-9 cells in a time- and concentration-dependent manner with approximately a 1500-fold increase in viral activity. Similar results were also obtained with a MT-4 cell line resistant to viral cytopathycity. In contrast, U-937 monocytoid cells did not respond to HC with an increase in viral activity, suggesting that the effect of the steroid on HIV replication may be cell-specific. Glucocorticoid receptors were present in both H-9 and U-937 cells but the level in U-937 cells was lower than that found in H-9 cells. We conclude that glucocorticoids can regulate HIV in a cell-specific manner and this effect may be mediated through GR.

T.C.P.111

CHARACTERIZATION OF HIV-1 CLINICAL ISOLATES RESISTANT TO ZIDOVUDINE (AZT).

Rooke, Ronald; Tremblay, M.; and Wainberg, M.A.
Jewish General Hospital, Montreal, Canada and Department of Microbiology and Immunology, McGill University, Montreal, Quebec, Canada.

Objective. To demonstrate whether HIV-1 possessing a AZT-resistant phenotype might emerge under conditions of AZT drug therapy.

Methods. Sequential viral isolates were obtained by co-culture methods from patients receiving AZT. Four such isolates obtained from the same patients at weeks 0, 36, 42 and 51 after initiation of treatment were amplified by growth on peripheral blood lymphocytes from healthy individuals. The same amounts of reverse transcriptase (RT) activity from these cultures (5,000 cpm/ml) were plated and serially diluted (1:2) in 96 well plates (2.5×10^6 cells/100 μl/well) either in the presence or absence of AZT (7 μM). After 10 days, HIV-1 specific immunofluorescence and RT activity were estimated. Six different patients were screened in this way.

Results. In 4 of the 6 patients, no viral growth was ever detected in the presence of AZT. However, while isolates from weeks 0, 36 and 42 of two other patients were incapable of growing in the presence of AZT, virus from week 51 did grow out, even when diluted 1:64. Further characterization showed that none of the earlier isolates from these patients could grow in the presence of 0.5 μM AZT, while the isolates from week 51 replicated actively at concentrations up to 10 μM.

Conclusion. Treatment of patients with AZT may select out variants of HIV-1 able to replicate in the presence of the drug. The detection of such variants does not seem to occur at high frequency.

T.C.P.112

THE EFFECT OF HIV INFECTION ON MONOCYTE DIFFERENTIATION.

Geleziunas, Romas; Boulerice, F.; Bour, S.; and Wainberg, M.A.
Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, and Department of Microbiology and Immunology, McGill University, Montreal, Quebec, Canada.

Two monocytic differentiation markers were examined after HIV infection of U-937 cells: 1) cell surface CD4 antigen levels, 2) myc and fos oncogene mRNA quantities. First, a nearly complete depletion of cell surface CD4 was observed in HIV-infected monocytes. This is similar to the rapid and permanent down-regulation of CD4 occurring during PMA-induced differention of U-937 cells. RNA blot hybridization experiments in conjunction with immunoprecipitation assays revealed that a post-transcriptional inhibitory event is responsible for CD4 down-regulation in both HIV-infected and PMA-treated U-937 cells. Second, c-myc mRNA levels are slightly decreased, while the c-fos mRNA precursor is more abundant in chronically infected U-937 cells, suggesting a possible mRNA processing defect in HIV-infected monocytes. These studies show that HIV may be modulating certain events leading to terminal monocyte differentiation.

T.C.P.113

CHROMOSOMAL LOCALIZATION OF TAT-INTERACTING CELLULAR FACTORS

Michael Newstein and Peter R. Shank, Division of Biology and Medicine, Brown University, Providence, Rhode Island, 02912 USA

Objective: To determine whether murine cells are resistant to tat-mediated transactivation due to the absence of factor(s) present in human cells and to determine whether rodent-human cell hybrids can be used to determine the human chromosomes which encode this factor or factors.

Methods: Various constructs expressing either the bacterial chloramphenicol acetyl transferase gene (CAT) or portions of the human growth hormone gene (HGH), driven from the HIV-1 LTR were introduced into various cell types by transfection in the presence or absence of a plasmid which expressed the complete tat gene of HIV-1. The level of gene expression was determined with various in vitro assays. We are also developing a genetic selection for genes encoding these tat-interacting factors utilizing a construct in which the HIV-1 LTR drives transcription of the bleomycin resistance gene.

Results: Our data suggest that human-rodent cell hybrids can be used to localize a specific set of human chromosomes which encode tat-interacting factors. Our present data indicate that such factors are encoded by three or fewer human chromosomes.

Conclusions: Our results indicate that the non-responsiveness of rodent cells to tat-mediated trans-activation is due to the lack of human factors which can be supplied by a limited set of human chromosomes.

T.C.P.114

THE REV GENE PRODUCT OF THE HUMAN IMMUNODEFICIENCY VIRUS AFFECTS RNA LOCALIZATION.

M. Emerman[1], R. Vazeux[1], and Keith Peden[2]. [1]Unité d'Oncologie Virale, Institut Pasteur, Paris, France. [2]John Hopkins University School of Medicine, Baltimore, USA

Objective: To characterize the Rev-dependent and Rev-independent expression of the HIV-1 envelope proteins.

Methods: We have constructed plasmids that contain various regions of the envelope gene and different 3' untranslated ends. The normal splice donor for Tat and Rev which is about 150 bp 5' to the start codon for the envelope gene, was removed and these plasmids cannnot express either Tat or Rev. Envelope expression following transfections of these plasmids both with and without another plasmid expressing Rev was examined by analysis of RNA and immunoprecipitation of labelled proteins.

Results and Conclusions: In the absence of the homologous RNA splice sites, the dependence of Env expression on Rev was found to be post-transcriptional. By in situ hybridization analysis we found that Rev affects the nuclear versus cytoplasmic localization of envelope-specific RNA. Several cis-acting sites in the envelope gene are involved in its regulation. One of these is needed for the Rev response. Two others negatively affect expression by retaining the RNA in the nucleus in the absence of the rev gene product and its response element. In addition, heterologous sequences at the 3' end of the Env mRNA are able to modify its dependence on the rev gene product.

T.C.P.115 EFFECT OF MUTATIONS IN VPX ON THE INFECTIVITY OF VIRAL PARTICLES OF HIV-2.

... Guyader[1], M Emerman[1], L Montagnier[1] and Keith Peden[2], Institut Pasteur, Paris, France[1], and Johns Hopkins University School of Medicine, Baltimore, USA[2].

Objective: To determine whether the vpx open reading frame, which is present in HIV2 and SIV genomes but has no counterpart in HIV1, is expressed in infected cells and to investigate the phenotype of VPX mutants. Methods and Results: Two anti-peptide sera raised to the predicted product of the HIV-2 vpx open reading frame immunoprecipitated a 16-kd protein from the cell extract and medium of cells infected with HIV-2, and a 14-kd protein from SIV-infected cells. We used site-directed mutagenesis to introduce two types of mutations in the vpx open reading frame. Cell-free supernatants from SW480 cells transfected with the mutated HIV-2 proviral clones were used to infect several CD4$^+$ lymphocyte and monocyte cell lines as well as fresh peripheral blood lymphocytes. Mutations in the vpx open reading frame eliminated the synthesis of the 16-kd protein, confirming that this protein is the product of this gene. Full-length clones of HIV-2 containing these mutations are infectious in two established lymphocyte cell lines and a monocyte cell line. In contrast, they show a severe defect in their ability to infect peripheral blood lyphocytes. Conclusion: These findings suggest that the VPX protein may be important in the in vivo life cycle of the HIV-2/SIV viruses.

T.C.P.116 EXPRESSION IN E.coli AND PURIFICATION IN ONE STEP OF A FUNCTIONAL HYBRID PROTEIN BETWEEN A BACTERIAL PERIPLASMIC PROTEIN (MALE) AND THE T LYMPHOCYTE-HELPER INDUCER-CD4 PROTEIN (SOLUBLE PART).

CLEMENT, Jean-Marie* ; SZMELCMAN, S.* ; SCHWARTZ, O.** ; HENIN Y.** ; MONTAGNIER L.** & HOFNUNG M* et al. * P.M.T.G. & ** Oncologie Virale, INSTITUT PASTEUR, 25 rue du Dr. Roux, Paris 75015, France.

The surface glycoprotein CD4, expressed on helper/inducer T lymphocytes, serves as the HIV receptor through binding of the virus envelope protein gp120. It was recently demonstrated that the soluble truncated moiety of CD4 (the 177 N terminal amino acids) retains the ability to bind gp120 and to neutralize the HIV particule.

We describe the purification and characterization of a recombinant protein produced by *E.coli* that contains the HIV binding portion of the human CD4 molecule, fused to the periplasmic maltose binding protein (MalE) of *E.coli*.This fusion protein retains the functional properties of its two constituents:

1. It binds maltose and maltodextrins.This property is used in a one step procedure to purify the recombinant protein by affinity on a amylose column with elution in mild conditions.
2. It binds purified gp120 and neutralizes HIV particles *in vitro* ;it is also recognized by the monoclonal neutralizing antibodies IOT4 and OKT4A.

The easy purification of active soluble MalE-CD4 protein from bacteria should facilitate a number of studies such as screening and possibly selection of CD4 mutants with altered properties (stability, interaction with virus etc), investigation of therapeutic potential of CD4, determination of CD4 structure by X ray cristallography.The CD4-MalE hybrid could also be useful as a reagent for various purposes: diagnostic, HIV virus purification isolation of HIV mutants...

T.C.P.117 CONSTITUTIVE SYNTHESIS OF NF-κB-LIKE NUCLEAR PROTEINS IN MONOCYTES- AN EXPLANATION FOR HIV LATENCY?

Nancy McCartney-Francis* and Michael Norcross**
*NIDR, NIH and **FDA, Bethesda MD, U.S.A.

Objective. To determine if host nuclear elements contribute to the regulation of HIV-1 gene expression in normal human monocytes.

Methods. Nuclear proteins were prepared from freshly isolated and cultured monocytes and analyzed for NF-κB binding activity to HIV-1 LTR and mutant double-stranded oligonucleotides by gel retardation assays. Monocyte activation was monitored by IL-1 synthesis and IL-2 receptor expression.

Results. Nuclear proteins isolated from 18 hr unstimulated and LPS-activated monocytes contain specific NF-κB binding activity as observed by binding to oligonucleotides encoding a single NF-κB enhancer region from the HIV-1 LTR. No binding was observed to a mutant sequence. Specific binding could be blocked by unlabeled wild-type oligonucleotides but not by the mutant oligomer. Surprisingly, freshly isolated monocytes (IL-2 receptor and IL-1 negative) and LPS-stimulated monocytes expressed equivalent amounts of NF-κB binding activity.

Conclusions. Resting monocytes constitutively express NF-κB-like binding proteins and the level of expression is unchanged by the state of activation. Whereas NF-κB has been shown to stimulate HIV-1 gene expression in T lymphocytes, it appears unlikely that NF-κB expression is solely responsible for the functional and phenotypic changes in monocyte activity following HIV-1 infection. The constitutive synthesis of NF-κB binding proteins in circulating monocytes may explain the persistence of HIV-1 in macrophages throughout the clinical course of AIDS.

T.C.P.118 ACTIVATION OF THE HIV AND INTERFERON REGULATORY ELEMENTS IN HEMATOPOIETIC AND EPITHELIAL CELLS.

Hiscott, J., Cohen, Lucie, Leblanc, Jean-Francois, Sportza, L., and Xanthoudakis, S. Lady Davis Institute, Jewish General Hospital, and Dept. of Microbiology and Immunology, McGill University, Montreal, CANADA

Objective. The interferon-β promoter contains several functional domains that confer virus-inducibility to the structural IFN gene. Interestingly, one of these specific elements, the P2 domain (GGGAAATTCC; -64 to -55: relative to the mRNA start site), shares 80% sequence homology with the two NF-kB recognition sites (GGGACTTTCC) within the U3 enhancer element of the HIV long terminal repeat (LTR). This observation prompted us to measure the transcriptional activity of dimers of P2 and NF-kB motifs in a transient expression assay using epitheloid (293), T-lymphoid (Jurkat), and myeloid (U937) cell lines.

Methods & Results. Cells were transfected with expression vectors containing various synthetic IFN and HIV regulation motifs linked to the CAT reporter gene and subsequently induced with Sendai virus and/or phorbol esters. Both regulatory elements displayed similar patterns of inducible gene expression. Furthermore, specific inducible protein-DNA complexes were identified between P2 or HIV enhancer by band retention assays using uninduced and induced extracts from hematopoietic and epithelioid cell lines. Competition analysis suggested that the IFN P2 domain and HIV enhancer could interact with similar DNA binding proteins.

Conclusion: Together, these results suggest that induction of IFN gene expression may share mechanistic similarities with the activation of the HIV-LTR.

T.C.P.119 DETECTION OF A NOVEL DNA TOPOISOMERASE I ACTIVITY ASSOCIATED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) AND OTHER RETROVIRUS PARTICLES

Priel, Esther* **; Yosef, O.**; Segal, S.**; Aboud, M.**; Showalter, S. D.***; Roberts, M.****; Oroszlan, S.****; and Blair, D. G.*
*Laboratory of Molecular Oncology, National Cancer Institute, Frederick, MD 21701-1013; **Ben-Gurion University, Beer-Sheva, Israel; ***Program Resources, Inc., Frederick, MD 21701-1013; ****Bionetics Research, Inc., Frederick, MD 21701-1013, USA.

The viral replication cycle is undoubtedly dependent on numerous topological changes of the viral and host genomes. Since DNA topoisomerases have been shown to be responsible for the topological changes of DNA, it was of interest to investigate whether a topoisomerase activity could be demonstrated in retroviral particles.

In this work we demonstrate the existence of DNA topoisomerase I (topo I) activity associated with two strains of purified HIV-1, equine infectious anemia virus (EIAV) and Moloney murine leukemia virus (MO-MuLV). The relaxation activity from these viruses was inhibited by camptothecin (CPT), a specific topo I inhibitor. The viral associated topo I activity is Mg^{++} dependent and possesses other characteristics different from the host cell enzyme. The viral associated topo I activity was removed from the viral lysate by anti-topo I serum. Western blot analysis indicates that an 11.5 Kda protein from both strains of HIV-I and an 11 Kda protein from EIAV is recognized by this anti-topo I serum. No similar protein can be detected in the appropriate nuclear or cytoplasmic cell extracts.

T.C.P.120 NEF RESPONSIVE SEQUENCES (NRS) OF THE HIV-1 LTR-MEDIATE TRANSCRIPTIONAL SUPPRESSION

Lee Ratner and TMJ Niederman, Departments of Medicine and Microbiology & Immunology, Washington University, St. Louis, Mo., USA

Objective: The nef gene of HIV-1 encodes a 206 amino acid, 27 kd product that down-regulates virus replication. This effect is mediated by NEF suppression of transcriptional initiation. This study identified a cis acting element in the HIV-1 LTR which is responsive to NEF.

Methods and Results: Two proviral HIV-1 clones were constructed, pHIV F+ which bears an intact nef gene, and pHIV F- which has a 45 base pair deletion in the 5'portion of nef. These plasmids were transfected into COS-1 cells. Nuclear run-off, Northern blot hybridization, and radioimmunoprecipitation assays demonstrated that NEF suppresses RNA initiation and viral RNA and protein levels 2-10-fold. A NEF expression vector, pSVF, was made using an SV40 promoter. Co-transfection of pSVF in 4-fold excess with HIV-1-LTR-CAT resulted in an 8-fold depression of CAT activity. NEF-mediated suppression was dose-dependent and was specific for the HIV-1-LTR in that the SV40 promoter, and the LTRs of HTLV-I, MPMV, and RSV were unaffected. HIV-1-LTR CAT deletion mutants were used to map the NRS. These constructs were co-transfected into COS-1 cells with or without pSVF or a TAT expression clone. LTR mutants with nucleotides -65 to +33 relative to the RNA initiation site were responsive to NEF, whereas those with nucleotides -48 to +33 were unresponsive. Conclusions: NEF is a specific transcriptional silencer of the HIV-1 LTR acting through sequences between -65 and +33. The activity of NEF is independent of that of TAT. Precise definition of NRS, possible interactions with SP1 and TATA-binding factors, and the mechanism of transcriptional silencing are being investigated.

T.C.P.121 MYRISTOYLATION DEPENDENT ASSEMBLY OF INFECTIOUS HIV-1

Lee Ratner* and ML Bryant^, Departments of Medicine* and Pediatrics^, Washington University, St. Louis, Mo., USA

Objective: Linkage of myristic acid via an amide bond to the amino-terminal Gly residue of the GAG precursor of mammalian retroviruses appears to facilitate an essential step in virus assembly. The goal of this study was to determine if myristoylation of the HIV-1 GAG precursor and MA protein are required for replication and infectious particle production.
Methods: Oligonucleotide-directed mutagenesis was used to change the codon for the N-terminal Gly of GAG to an Ala codon in a functional HIV-1 proviral clone, HXB2. The mutant plasmid, HX-GAG-A1, and the parental plasmid were transfected into two CD4- cell lines, COS-1 and HeLa, and CD4+ Jurkat cells. On day 4 following transfection, the CD4- cells were cocultivated with H9 cells to support propagation of infectious virions.
Results: Viral antigen was detected following transfection of each of the CD4- cell lines with either HXB2 or HX-GAG-A1. However, sucrose gradient analysis of culture supernatants revealed only soluble GAG protein, and no detectable virus particles. Moreover, infectious virus was not produced following cocultivation with susceptible H9 cells, or direct transfection of Jurkat cells. In contrast, transfection of each of the cell lines with HXB2 plasmid produced infectious virus. Cotransfection of the CD4- cells with HX-GAG-A1 and a GAG-POL expression plasmid resulted in virus replication, demonstrating complementation of this defect.
Conclusion: Myristoylation of the HIV-1 gag polypeptide is required for virus replication and assembly. These data suggest that inhibition of myristoylation will open a new avenue of anti-retroviral research.

T.C.P.122 BIOLOGICAL SIGNIFICANCE OF HIV-1 ENVELOPE HETEROGENEITY

Terry McNearney, P Westervelt, BJ Thielan, D Trowbridge, J Garcia, and L Ratner. Departments of Medicine and Microbiology & Immunology, Washington University, St. Louis, Mo., USA

Objective: To examine the nature and biological significance of naturally occuring mutations in HIV-1's derived from blood, brain, and lung of 3 patients infected with a single progenitor virus. Methods and Results: Isolates were obtained from short term PBMC cultures cocultivated with fresh tissue from an asymptomatic, HIV seropositive blood donor (pt I), and two neonatal transfusion recipients who subsequently developed AIDS (pts II & III). Isolates from the lung and brain of pts II & III replicated to 100-fold higher levels on monocytes relative to the blood isolates from the same patients; no growth differences on lymphocytes were observed. The 3'portion of the genome was cloned from each isolate, and env sequenced. The predicted amino acid sequence from the blood isolate of pt I shows a 16% divergence compared to clone HXB2. The positions of Cys residues are conserved in SU. Among the sequences from 10 clones from this clustered HIV outbreak, there are only 0.1% amino acid sequence differences from one another. No unique amino acid changes are found in the clones derived from the brain or lung isolates. All clones derived from these patients exhibit 2 termination codons in the portion of env encoding TM. Conclusions: The envelope amino acid sequence variation observed in these neonates is considerably lower than that reported for adults with AIDS, possibly reflecting the host's limited ability to provide selection pressure. The lack of a consistent difference in env between clones derived from isolates which show markedly different replication on monocytes suggests that other portion(s) of the HIV-1 genome may be contributing to cell specificity.

T.C.P.123 HIV INFECTION OF COLONIC MUCOSA ASSOCIATED WITH COLITIS

J.M. Mathijs, M. Hing, C. Goldschmidt, D.A. Cooper. and A.L. Cunningham Virology Unit, Westmead Hospital, Centre for Immunology, St Vincent's Hospital NHMRC Special Units for Clinical Research and Epidemiology and AIDS Virology,Sydney Australia.

The aetiology of diarrhoea in patients infected with the human immunodeficiency virus infection often remains obscure. We report 7 patients with human immunodeficiency virus infection with chronic diarrhoea for longer than 6 months, rectal bleeding, abdominal pain and stool leukocytosis. The mucosal pattern on colonoscopy showed diffuse proctocolitis. Colonic biopsies showed moderate to severe colitis characterised by preservation of normal crypt architecture and a mixed inflammatory cell infiltrate. These features were not compatible with a diagnosis of chronic inflammatory bowel disease. HIV nucleic acid was identified by in situ hybridisation in colonic biopsies from 4 out of 6 patients. Autoradiographic grains were distributed in clumps over epithelial cells of the colonic glands (not confined to argentaffin cells) and over cells in the lamina propria. Hybridization-histochemistry is being used to identify the latter cells. No other microbial agent could be demonstrated as the cause of diarrhoea. At presentation all patients had CD4+ lymphocyte counts greater than 150 X 10^6/L and none had AIDS. We suggest that this chronic colitis is a new entity related to infection of the colon with the human immunodeficiency virus.

T.C.P.124 ANALYSIS OF HIV SEQUENCE CHANGE DURING INFECTION

Leigh Brown, Andrew J. and Balfe, P. University of Edinburgh, Edinburgh, Scotland, UNITED KINGDOM

Objective. To develop a method of analysis which will detect selection for HIV sequence variants during infection.
Methods. The probability that more than one lineage will be found in a sample taken n generations after the first has been estimated using the method of branching processes (Haldane 1927). The approach has been applied to the data of Saag et al. (Nature 334, 440; 1988).
Results. By phylogenetic analysis based on the Wagner parsimony method we have found that the WMF3 group of clones originated from within the WMF1 group isolated 16 months earlier and did not arise in parallel. Thus, after 16 months all but one WMF1 lineage had become extinct.
We have examined the probability of loss of all but one lineage in these data assuming no selection and a generation time of 5 days (based on observations made during virus isolation in our laboratory). The probability of more than one lineage persisting was found to be less than 0.05.
It is therefore not necessary to invoke selection to explain the relationships between the WMF3 and WMF1 clones.
Conclusions. The method we have used will be effective at detecting selection when the number of generations between samples is 30-50 (about 5-8 months). There is no evidence on these data for selection among clones isolated from patient WMF3.

T.C.P.125 LOCALIZATION OF A DOMAIN OF HUMAN CD4 REQUIRED FOR HIV-MEDIATED SYNCYTIUM FORMATION BY COMPARISON WITH CD4 cDNAs ISOLATED FROM THE CHIMPANZEE AND RHESUS MONKEY

David Camerini and Brian Seed, Dept. of Molecular Biology, Massachusetts General Hospital and Dept. of Genetics, Harvard Medical School, Boston, MA, U.S.A.

Objective. To locate regions of the Human CD4 glycoprotein required for HIV-1 mediated syncytium formation.
Methods. We have isolated, sequenced, and expressed cDNAs encoding the CD4 glycoproteins of the chimpanzee (Pan troglodytes) and the rhesus monkey (Maccaca mulatta). We performed HIV-1 infection, binding and fusion assays using cell lines expressing these antigens. We constructed trans-species hybrid CD4 antigens in vitro, and tested their ability to promote HIV-1 mediated syncytium formation.
Results. Both the chimpanzee and rhesus monkey CD4 antigens, respectively 99% and 92% homologous to their human counterpart, bind HIV-1 and permit infection when expressed on HeLa cells. Nevertheless, these non-human receptors are markedly less efficient than human CD4 at promoting HIV-1 mediated syncytium formation. We have located individual amino acid differences between the human CD4 and these non-human CD4 glycoproteins, responsible for their differing abilities to participate in HIV mediated syncytium formation.
Conclusion. We have defined a region of the human CD4 glycoprotein, distinct from the previously defined binding site for HIV-1, which is essential for the formation of syncytia in the presence of the external and transmembrane glycoproteins of HIV-1.

T.C.P.126 STUDIES ON THE FUNCTION OF VPX IN HIV-2

Kappes, John C.*; Decker, W.D.*; Lee, S-W.*; Morrow, C.D.*; Shaw, G.M.*; and Hahn, B.H.*
*University of Alabama at Birmingham, Birmingham, Alabama, USA.

Objectives. To determine the role of vpx in the life cycle of HIV-2.
Methods. To study the biological function of vpx, we constructed a transfection-competent plasmid clone of HIV-2$_{[illegible]}$ and utilized it for site-directed mutagenesis of the vpx open reading frame. An internal HindIII (vpx containing fragment) was subcloned into M13 and mutagenized so as to abolish vpx translation. The role of vpx was then assessed *in vitro* by comparing vpx-deficient and wild-type virus with respect to replication efficiency, syncytia induction, virus-protein expression, cytopathicity, infectivity and reverse transcription. For *in trans* complementation studies, HIV-2 vpx was subcloned into a eukaryotic expression plasmid and expressed in cos-1 cells.
Results. Functional analyses comparing vpx-deficient and wild-type HIV-2 indicated that vpx is not required for virus replication *in vitro* in two immortalized T-cell lines as well as in peripheral blood lymphocytes (PBL). Upon transfection into immortalized T-cell lines (SupT1 and CEMx174) syncytia induction, reverse transcriptase levels and virus encoded structural protein products were found to be comparable for vpx-deficient and wild-type HIV-2. Both mutant and wild-type viruses were infectious and equally cytopathic when transmitted cell-free to SupT1 cells. Similarly, vpx-deficient and wild-type HIV-2 were infectious and replication competent in PBL. Electron microscopy revealed no apparent differences in virus ultrastructure and morphology. Comparison of unintegrated virus DNA intermediates following high titer infection of SupT1 cells demonstrated that virus binding, uptake, uncoating and reverse transcription were equivalent in mutant and wild type viruses. Finally, cotransfection of cos-1 cells with a vpx-deficient HIV-2 provirus and a eukaryotic vpx expression plasmid resulted in the production of vpx containing virions and demonstrated that vpx can be complemented *in trans*.
Conclusions. Vpx is not required for HIV-2 replication and cell-free transmission in immortalized T-cells as well as in PBL *in vitro*. Similarly, the lack of vpx does not seem to affect early events in the viral life cycle. Since vpx is packaged within mature virions, it might be involved in HIV-2 assembly or particle stability. *In trans* complementation experiments are underway to further characterize the packaging requirements for vpx and to determine whether vpx can be packaged into HIV-1 virions.

T.C.P.127 COMPARATIVE ANALYSIS OF HIV-1 AND HIV-2 GENE EXPRESSION

Arya, Suresh K. and Gallo, R.C.
National Cancer Institute, NIH, Bethesda, Maryland, USA

Objective. HIVs may comprise a spectrum of retroviruses with varying pathogenicity and/or latency which may partly be determined by their regulatory genes and regulatory elements. The objective of this study was the comparative analysis of the regulatory genes and elements of HIVs with varied pathogenic potential. Methods. Functional and mutational analysis of the regulatory genes and response elements by DNA mediated transfections. Results. Pathogenic HIV-1 (III_B) and HIV-2 (NIH_Z) as well as HIV-2 with attenuated cytopathicity [HIV-2(ST)] all contain functional tat, nef, and rev genes. Additionally, their expression is equally activated by T cell activation and CMV transactivation. Interestingly, the tat and T cell activation response elements in HIV-1 and HIV-2 are structured differently. For example, even though HIV-2 contains the designated enhancer element identical to that in HIV-1 where it responds to T cell activation (NFκB site), the major such element of HIV-2 is located upstream and is supposedly a member of a family of response elements. The HIV-1 and HIV-2 transactivation by the tat and CMV transactivator gene involves transcriptional activation including chain initiation and elongation, with CMV affecting elongation more than the initiation. Conclusion. While HIV-1 and HIV-2 may utilize subtly different pathways of gene activation, they both contain functional tat, nef and rev genes and response elements including those responsive to T cell activation and CMV transactivation. Thus, the possible differences in their pathogenicity may not reside in the functional capacities of the regulatory genes and elements alone.

T.C.P.128 RESTRICTION MAP PATTERNS IN SELECTED CLINICAL PAIRS OF HIV ISOLATES.

Vahey, MaryAnne; McCutchan, F.; Mosca J.; Redfield, R.; Burke, D., and the Walter Reed Retroviral Research Group, U.S.A.

Objective. To evaluate restriction mapping of selected viral isolates to determine the potential value of application in defining the identity of viral isolates.
Methods. Primary viral isolates were obtained by co-cultivation with normal PBMC using standard techniques. Southern blots of restriction enzyme digests of viral DNA probed with 32P labeled SST fragment of pBH10.
Results. Specific paired samples were selected and viral isolates obtained. Group 1 consisted of 4 sequential isolates pairs (less than 6 weeks apart) from the same patient (two early HIV infection and two late HIV infection). Group 2 consisted of 2 isolate pairs from same patient however different body fluid source (CSF/PBMC). Group 3 consists of same patient same time different isolation techniques (T cell versus monocyte). Group 4 consists of epidemiological pairs to include spouse and spouse/newborn pairs. Restriction patterns of pair isolates will be compared to unrelated isolates to develop an identity score.
Conclusion: These results demonstrate the applicability of restriction mapping in defining viral identity.

T.C.P.129 A STRATEGY FOR THE DETECTION OF SPECIFICALLY SPLICED mRNAs ENCODING HIV-1 REGULATORY GENES

Guatelli, John*; Richman, D.*; and Gingeras, T.**
*Depts. of Medicine and Pathology, UCSD School of Medicine, San Diego, California, 92161 USA. **The Salk Institute Biotechnology/Industrial Associates, Inc. (SIBIA), La Jolla, California, 92037 USA.

Objective. To differentially detect spliced mRNAs encoding the HIV-1 regulatory genes tat, rev, and nef in order to study the temporal expression of these transcripts during infection in vitro.
Methods. Primer-directed nucleic acid amplification was used to generate cDNA fragments of characteristic length which reflected gene-specific RNA splicing events.
Results. Total cellular RNA from HIV-1-infected CEM cells was amplified using primers complementary to: 1) the sequence immediately 5' of the splice donor common to all processed HIV-1 RNAs (5' of the gag start codon); and 2) the sequence at the 3' end of the tat and rev 5' coding exons. Between these two sequences are three splice acceptors whose use has been suggested to lead to specific mRNAs encoding tat, rev, and nef. The predicted cDNA fragments of 290, 108, and 92 base pairs, reflecting tat, rev, and nef mRNAs, respectively, have been detected using specific oligonucleotide probes. Several cDNA fragments of unexpected size have also been detected. Characterization of these fragments will be discussed.
Conclusion. Although differential detection of HIV-1 regulatory gene transcripts is difficult because of their similar size and largely shared nucleotide sequences, gene-specific splice events can be detected utilizing primer-directed amplification. This approach can be used to analyze the order of expression of these transcripts during infection.

T.C.P.130 PROCESSING OF THE *gag* POLYPROTEIN BY HUMAN IMMUNO DEFICIENCY VIRUS PROTEASE OCCURS IN A SEQUENTIAL MANNER

S. Erickson-Viitanen, John Manfredi, Paul Viitanen, David Tribe, Radonna Tritch, Ronald Swanstrom, et al. E.I. DuPont de Nemours and Co., Inc, Medical Products Department, Wilmington, De, USA 19880-0400 and Departments of Biochemistry and Microbiology and Immunology, University of North Carolina at Chapel Hill, Chapel Hill, No. Carolina, 27599.

The virally encoded protease of human immunodeficiency virus is responsible for the processing of the *gag* and *gag-pol* polyprotein precursors to their mature polypeptides. Since correct processing of the viral polyproteins is essential for the production of infectious virus, HIV protease represents a potential target for therapeutic agents. In this study, full-length *gag* polyprotein has been synthesized *in vitro* to serve as a *trans* substrate for bacterially expressed HIV protease. The *gag* polyprotein is rapidly and completely processed by protease-containing extracts. Immunoprecipitations with monoclonal antibodies to p17 and p24 suggest that initial cleavage of the polyprotein occurs at the p24-p15 junction. The proteolysis was inhibited by pepstatin with an IC_{50} of 0.15 mM for cleavage at the p24-p15 junction and 0.02 mM for cleavage at the p17-p24 junction.

T.C.P.131 POLYMERASE CHAIN REACTION IN HIV INFECTION

Mariotti, M.*; Lefrère, Jean-Jacques*; Berriche, S.*; Vittecoq, D.**; Noël, B.*; Ferrer-le-Cœur, F.*; Girot, R.**; Rouger, P.*.
* F.N.T.S., Paris, ** Hôpital Necker, Paris *** C.T.S., Chambéry, France.

Objective. Use of Polymerase Chain Reaction (PCR) in human immunodeficiency virus (HIV)-infected subjects and in seronegative but high risk subjects.
Methods. Localisation on HIV 1 genome and nucleotide sequence of the primers and probes used (derived from conserved regions of the viral genome) were :

- GAG : primer I 1088-1115, primer II 1175-1202, probe 1132-1172
- POL 1 : primer I 2391-2416, primer II 2672-2698, probe 2539-2575
- POL 2 : primer I 4118-4135, primer II 4242-4259, probe 4167-4205

Slot-blot and Southern-blot analysis were used in detection of HIV sequences.
530 subjects were studied : 200 non-haemophiliac HIV seropositive (Elisa with confirmation by Western-blot) subjects (amongst them, ten were seronegative 6 months earlier) ; 40 haemophiliac patients (20 seropositive + 20 seronegative) ; 25 AIDS patients ; 25 seronegative polytransfused thalassaemia patients ; 20 subjects with isolated and persistent anti-core antibodies (anti-p25 or anti-p18) ; 20 seronegative partners of HIV seropositive subjects (a second sample was collected and studied 6 months later in all) ; 200 healthy seronegative blood donors as controls.
Results. 1) PCR is positive in the HIV seropositive subjects but some appear negative in this assay when using only one single primer pair and probe. The use of three sets of primers appears necessary to prevent false-negative results in this context. 2) No detection of HIV DNA was observed in seronegative subjects from high risk groups. 3) All control subjects were PCR negative.
Conclusion. PCR allows the identification of HIV DNA in seropositive subjects and confirms the absence of HIV infection in seronegative subjects.

T.C.P.132 IN-VITRO EXPRESSION OF A FUNCTIONAL HIV-NEF GENE PRODUCT

Poulin, Louise and Levy, J.A. Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To study the biochemical function of the HIV nef protein.
Methods: We have subcloned the HIV_{SF2} nef gene DNA from an original plasmid (pKK-ori B) provided by Paul Luciw (University of California Davis, CA) into a bluescript vector (Stratagene, CA). The new construct was used in a transcriptional reaction mixture to produce the nef mRNA. The generated messenger was then translated into a micrococcal nuclease treated reticulocyte lysate. Finally, the purified nef gene product was analyzed in an in-vitro assay for GTP binding ability and kinase activity.
Results: The nef mRNA encoded for a major protein of 27 K daltons as determined by polyacrylamide gel electrophoresis. This finding is in accordance to the predicted molecular weight and is similar to what is found in HIV-infected cells. This p27 is recognized by either specific nef monoclonal antibody (Dupont, MA) or prescreened anti-nef serum from human AIDS patients. In addition, three other products of 29Kd, 25Kd and 17Kd are also synthesized at a much lower level in this reaction and are also recognized by the same antibodies.

Immunoprecipitated nef proteins can bind specifically ^{32}P-alpha-GTP. Furthermore, the immunoprecipitated translation products display a kinase activity in the presence of either ^{32}P-gamma-GTP or ^{32}P-gamma-ATP. However, the phosphorylated product of this in-vitro kinase assay runs as a single band with a molecular weight of 45 to 50 K daltons on a polyacrylamide gel. The phosphotransfer activity is dependent of the concentration on the nef translated products used.
Conclusion: The HIV nef gene expressed in-vitro possesses an integral GTP binding ability and kinase ability. The establishment of an in-vitro system allows us to study the structure and the biochemical function of the purified nef protein known as a negative regulator of HIV expression.

T.C.P.133 TWO EPSTEIN BARR VIRUS LATENT PROTEINS (LMP AND EBNA2) TRANSACTIVATE THE HIV-1 LTR

Simurda, Maryanne C. and Hammarskjöld, M.-L.
Departments of Microbiology and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

We have constructed SV40 based vectors that express different latent proteins of Epstein Barr Virus (EBV). Using these constructs we have shown that both the nuclear EBNA2 protein and the latent membrane protein (LMP) are efficient transactivators of the HIV1 LTR. Both of these proteins are expressed in B lymphoid cells immortalized by EBV. To map the regions of the LTR involved in the transactivation we have used different mutated forms of the HIV-1 LTR linked to CAT as a reporter gene. CV-1, Ramos, Raji and Jurkat cells were co-transfected with these constructs and the vectors expressing EBNA2 and LMP. Results showed that most of the effect of the LMP protein could be mapped to the binding sites for nuclear factor κB (NF-κB). These results indicate that LMP activates second messengers that are involved in activation of NF-κB or related factors. The effect of the EBNA2 protein could not be mapped to a single defined cis-acting element and seems similar to that observed with immediate early proteins of other herpesviruses.

T.C.P.134 INFECTION OF RHESUS MACAQUES WITH A MOLECULARLY CLONED SIMIAN IMMUNODEFICIENCY VIRUS

Paul Luciw, M. Marthas, B. Banapour, T. McGraw, P. Marx and N. Pedersen, University of California, Davis, California, U.S.A.

Objective: To analyze rhesus macaques infected with a molecularly cloned SIV with respect to viral replication, virulence, and ability to elicit anti-viral immune responses.
Methods: An infectious molecular clone of SIV from a rhesus macaque was found to replicate to high titer in cultures of primary rhesus peripheral blood mononuclear cells (PBMC) and macrophages derived from rhesus PBMC. Six juvenile rhesus macaques were inoculated intravenously with SIV recovered from the molecularly cloned provirus.
Results: All animals seroconverted (by immunoblotting analysis) within five weeks post inoculation (PI) and virus was recovered from PBMC of all animals at one and two weeks PI. Antibodies to *env*-encoded proteins were detected before antibodies to the *gag-pol* precursor and *pol* gene products. Only one animal developed detectable antibody to the p27 *gag* gene product. Once antibodies to SIV-encoded proteins were elicited, they persisted; however, SIV-specific neutralizing antibody titers declined after one month PI. By ten months after inoculation three of the animals had exhibited transient viremia (as detected by co-cultivation with human lymphoid cells), three were consiently virus negative and none had developed clinical signs of SIV disease.
Conclusions: SIV from a molecular clone is capable of producing a persistent and, perhaps, latent infection in rhesus macaques; however, the outcome of infection appears to be dependent on the individual host. These animals remain under study to assess the pathogenic potential of an SIV isolate that has been shown to be both T-cell tropic and macrophage tropic.

T.C.P.135 DETECTION OF ACTIVE VIRAL PROTEASE ASSOCIATED WITH CAPSIDS OF EQUINE INFECTIOUS ANEMIA VIRUS (EIAV).

Roberts, Michael; and Oroszlan, S. BRI, Basic Research Program, NCI-Frederick Cancer Research Facility, Frederick, MD 21701-1013, USA.

The cores of retroviral particles are likely to contain all the components required for infection of the host cell once it has entered the cytoplasm. In this respect, it was of interest to prepare cores of EIAV as a model system for the human immunodeficiency virus (HIV).

In this work we have prepared cores of EIAV by treatment of whole virus with detergent followed by two cycles of rate-zonal banding through Ficoll density gradients. The major components of the core are the p11 (nucleocapsid protein) and p26 (capsid protein) which are present in equimolar amounts, as in the whole virus. Since the cores are not deficient in p26, they are referred to as capsids. The other *gag*-encoded proteins p9 and p15 are removed during the preparation. At pH 7.6, the presence of active viral protease in the capsids was revealed by cleavage of p11 to a p6 protein. This cleavage was inhibited with pepstatin, which is known to work with retroviral proteases. The existence of the capsid as a distinct morphological entity was shown by electron microscopy of negative stained particles. By this means, the capsids are revealed as uniform cone-shaped particles 60nm x 120nm in size. The significance of the p11 cleavage at this stage in the retroviral life cycle is being investigated.

(Research supported by the National Cancer Institute, DHHS, under contract NO. NO1-CO-74101 with Bionetics Research, Inc.)

T.C.P.136 EXPRESSION OF HIV GENES IN XENOPUS OOCYTES: DEMONSTRATION OF POSTRANSCRIPTIONAL REGULATION

Adeniyi-Jones, Samuel*, Klotman, Mary** and Josephs, Steve**
*Human Genetics Branch, NICHD, Bethesda, MD and Laboratory of Tumor Cell Biology, NCI, Bethesda, MD, USA

Objective: To study posttranscriptional aspects of HIV gene regulation in Xenopus oocytes.
Methods: Purified normal and mutant LTRCAT transcripts were synthesized using the bacteriophage T7 polymerase system. These were coinjected with plasmid DNA constructs into the nucleus and/or cytoplasm of Xenopus oocytes. CAT assays and RNA analyses were performed by standard methods.
Results: HIV genes can be faithfully and efficiently expressed in the Xenopus oocyte. We can demonstrate postranscriptional regulation of the normal LTRCAT construct. Constructs with TAR mutations express very low basal levels and are not regulated.
Conclusion: The Xenopus oocyte is a suitable system for the study of HIV gene expression. Our results suggest a postranscriptional TAR dependent regulation.

T.C.P.137 HIV-1 pol EXPRESSION IS DEPENDENT ON A GENERAL 'SHIFTY' SEQUENCE

Wilson, Wilma*; Braddock, M.*; Kingsman, S.M.* and Kingsman, A.J.*,**
*Department of Biochemistry, South Parks Road, Oxford, OX1 3QU, U.K.
**British Biotechnology Ltd., Watlington Road, Cowley, Oxford, U.K.

Objective. To determine the minimal sequence requirements for the frameshift event which is essential for pol expression and to examine the significance of this 'shifty' sequence in cellular genes.
Methods. We have used an SP6 in vitro system to assay a series of fragments and oligonucleotides for their ability to frameshift.
Results. We have shown that a short (26bp) sequence containing a run of 6 T's is sufficient for pol expression in both yeast and mammalian systems. We demonstrate that 6T's alone are able to direct frameshifting. Shifting occurs irrespective of the reading phase of the T's and occurs into both reading frames. The possibility of frameshifting occuring in other genes containing 6T's has been examined and we demonstrate shifting in a cellular gene which contains this 'shifty' sequence.
Conclusion. HIV-1 employs a general 'shifty' sequence of 6T's in its expression of pol. It is possible that the frequency of the shift is modulated by other viral proteins or by the particular sequence context.

T.C.P.138 MOLECULAR CHARACTERIZATION OF THE HUMAN CD4 GENE

Hanna, Zaher*; Cheung, E.* and Jolicoeur P.*,**.
*Clinical Research Institute of Montreal, Montreal, Quebec, Canada;
**Université de Montréal, Montreal, Quebec, Canada.

The human CD4 molecule has been shown to serve as a specific membrane receptor for HIV. To better understand the control of the expression of this gene as well as its specificity of expression in specific cell populations, we undertook its molecular cloning. Using the CD4 cDNA probe, we isolated a set of overlapping genomic clones from human genomic libreiries constructed in the lambda cloning vector EMBL-3. These clones span the CD4 gene and its adjacent sequences. Clones were characterized by restriction enzyme analysis and by Southern hybridization. The putative promotor has been identified and partially sequenced. Search has been initiated to identify enhancer sequences using transfection techniques with the CAT vector and by constructing transgenic mice.

T.C.P.139

REGULATION OF HIV-1 GENE EXPRESSION BY tat, rev AND nef.

Pavlakis, George N.*, Felber, B. K.*, Drysdale, C. M.*, Athanassopoulos, A.* and Schwartz, S. *.
* NCI-FCRF, BRI-Basic Research Program, Frederick, MD 21701 USA.

Objective. To study the mechanism of regulation of expression of HIV-1 by viral factors and the contribution of cellular factors to this process.
Methods. Gene transfer, mutagenesis, measurement of RNA and protein levels, cell fractionation, stability measurements, PCR amplification, polysomal profiles.
Results. Two viral regulatory proteins of HIV-1, tat and rev, are necessary for viral expression in human cells. A third regulatory protein, nef, has also been proposed to cause downregulation of transcription from the long terminal repeat (LTR) promoter, but is not essential for virus propagation in tissue culture. tat interacts with a cis-acting element in the R region of the LTR (TAR) and increases the steady state levels of all the viral mRNAs. Several experiments support a role of tat in transcriptional activation. In the absence of tat the majority of mRNA is not associated with the polysomes, suggesting a posttranscriptional effect of tat as previously postulated.
rev increases the levels of the viral mRNAs containing a cis-acting element (rev responsive element, RRE) localized in the env region of HIV-1. rev increases the levels of the unspliced viral mRNAs which contain RRE at the expense of the multiply spliced mRNAs not containing RRE by increasing the transport and cytoplasmic accumulation of unspliced mRNA. Splicing is not necessary for rev function. By promoting the transport of unspliced mRNA, rev decreases the accumulation of the multiply spliced mRNA. rev is produced by two classes of mRNA: (a) monocistronic, which have not been cloned previously as cDNA and (b) bicistronic, producing also tat protein. We have shown that rev acts at the RNA level to downregulate the levels of its own expression as well as the levels of tat and nef proteins.
Conclusion. Feedback regulation by the rev protein on the levels of the mRNAs producing tat, rev and nef is an essential regulatory circuit of HIV-1 allowing the balanced expression of the viral proteins and the generation of infectious virus. Intracellular and extracellular conditions disturbing this regulatory balance may have profound effects on the outcome of viral infection.

T.C.P.140

HIV INFECTION THROUGH ENDOCYTOSIS MEDIATED BY Fc-RECEPTORS OF MACROPHAGES

Nagy K.[o], Valentin A.[+], Szegei Gy.[x]
[o]Institute of Isotopes, Hungarian Acad. Sci., Budapest, [+]Dept. of Virology, Karolinska Institute, Stockholm, Sweden, [x]3rd Dept. of Internal Medicine, Debrecen, Medical University, Hungary

Objective To study the role of Fc-receptors in HIV infection of CD4 negative cells, using a recently established macrophage/monocyte cell line: DD as a model system.
Methods Membrane marker and biochemical characterisation of DD cells had been done by immunofluorescence (IF) and enzyme cytochemical methods. DD cells were cultured in various conditions, and infected with HIV: i., directly, ii., complexed with different titers of HIV-specific IgG. Viral replication were monitored with IF, reverse transciptase assay and electron microscopy.
Results DD cells express myelomonocytic differentiation antigen CD13, and Fc-II receptors on to the cell membrane. They are negative for FcR-I, Leu M3, HLA-DR and also for CD4 receptors even after receptor induction. They do not posses enzyme activity such as α-naphtyl acetate esterase, acid phosphatase, α-1-antitripsin and lysozyme. DD cells were not permissive for direct infection by HIV. Treatment of cells with immunocomplex, however, was followed by syncytia formation and extent cytopathy resulting in a complete destruction of cultures.
Conclusion We conclude that HIV could be endocytosed in form of an immunocomplex, by the DD cells lacking CD4 receptors specific for HIV, but because of the rapid CPE, cells were not able for active viral replications in this model system. We hypothesize, that this way Fc-receptors may play an alternative route for HIV infection in vivo too.

T.C.P.141

STUDY OF THE CD45R AND UCHL1 POSITIVE LYMPHOCYTE SUBSETS IN THE BLOOD OF HIV-SEROPOSITIVE (HIV-POS) AND HIV-SERONEGATIVE (HIV-NEG) HAEMOPHILIACS

Füst, G.[*], Pálóczi, K.[*], Beverly, P.[**], Ujhelyi, E.[*], Mihalik, R.[*], and Králl, G.[*]
[*]Natl.Inst.Haematol.Blood Transfusion, Budapest, Hungary, [**]ICRF Human Tumour Res., Immunol. Group, London, UK

Objectives. CD45R+ and UCHL1 lymphocyte subsets are thought to have different functions and are markers of the virgin and primed T lymphocytes, resp. Upon in vitro activation, a CD45R-UCHL1 switch occurs. It seemed therefore interesting to study if HIV infection influences the frequency of these subsets. Methods. Twenty-one HIV-pos (11 adults, 10 children) and 11 HIV-neg haemophiliacs (6 adults, 5 children) as well as 11 adult healthy controls (CO) were tested. UCHL1 and CD45R subsets were detected by monoclonals UCHL1 and SN130, resp., using FACS. Results. UCHL1+ cells exhibited reciprocal distribution to the CD45R+ cells in all 3 groups ($R=-0.53$, $p<0.0000001$). No significant differences were found in the percentage or absolute number of either subset between the HIV-pos, HIV-neg, and CO groups. By contrast, the 3 groups markedly differed from each other in the CD8/CD45R (HIV-pos: 0.69±0.25, HIV-neg: 0.43±0.18, CO: 0.28±0.10) and in the CD8/UCHL1 ratios. Interestingly enough, HIV-neg adult haemophiliacs had significantly more (53 vs 43%) UCHL1, and less (53 vs 75%) CD45R cells than the HIV-neg haemophiliac children. Conclusion. HIV infection does not alter the frequency of UCHL1 and CD45R subsets in the peripheral blood. Due to the alterations of other subpopulations, however, cells of both subsets include much more CD8+ cells in HIV-infected patients than in the healthy persons.

T.C.P.142

THE IMMUNOMODULATING AND ANTIVIRAL EFFECTS OF AS101, AN ORGANOTELLURIUM COMPOUND

Vonsover, Ami; Kalechman, Y.; Oron, M.; Shalit, F.; Albeck, M.; Sredni, B., *et al.*
Bar Ilan University, Ramat Gan, Israel.

Objective. Two common approaches to the treatment of AIDS are the use of antiviral drugs and immunological enhancement. We tested AS101, an organo-metallic compound (Nature 330:173, 1987), for these activities.
Methods. We evaluated the effects of AS101 on various parameters concerning activation and function of immunocompetent cells as well as its antiviral effects assayed by determinations of the reverse transcriptase (RT) activity in supernatants from HIV infected cells.
Results. AS101 induced the expression of IL-2 receptors, the production of IL-2, colony-stimulating factor (CSF), IL-3, TNF and INFs, both *in vitro* and *in vivo*. AS101 also enhanced the ratio of OKT4 to OKT8-positive cells in cultured mononuclear cells from AIDS patients. Phase I clinical trials currently in progress on patients with AIDS or cancer show a general enhancement in the abovementioned immunological parameters.
AS101 was also found to protect mice from adverse effects of irradiation through increasing the number of spleen and bone-marrow (BM) cells, the number of BM CFU-C, and the production of CSF. *In vitro* studies with HUT78-chronically infected and with peripheral mononuclear cells infected with HIV show that AS101 had an antiviral effect. This was demonstrated by inhibition of particulate associated RT activity in the supernatants of the infected cells.
Conclusion. These findings indicate that AS101 acts as an immunomodulator and as an antiviral agent. AS101 may therefore prove useful in the treatment of AIDS patients.

T.C.P.143

A NUCLEOTIDE SEQUENCE OF UNKNOWN FUNCTION AMPLIFIED FROM DNA POLYMERASE CHAIN REACTION(PCR) IN HIV-INFECTED CELLS.

Wu-Tse Liu*,Siau-Ting Hu*,Shih-Rong Wang**.
*National Yang-Ming Medical College and **Institute of Biomedical Science,Academic Sinica,Taipei,Taiwan,R.O.C.

Objective : To discovery the nucleotide sequence amplified by PCR from HIV-infected cells.
Method : The selective primers SK38/SK39 was used for HIV-1 and SK39/SK90 for HIV-2 identification using PCR single - stranded dideoxy method employing pBlueScript II was used for nucleotide sequencing.
Result : Using PCR, the virus strain from chinese homosexual patient with AIDS was identified as HIV-1, not HIV-2. During the PCR reaction, a DNA fragment of 1.4 kb was always seen in the gel when DNA from HIV-infected cells employed. Nucleotide sequence of this fragment showed that this 1.4kb fragment was flanked by SK 39 primer sequence in an inverted orientation. This sequence so far has 77% homology to c-myc and only 44% homology of HIV.
Conclusion : A nucleotide sequnce of unknown function was amplified by PCR from HIV-infected cells. The meaning of this sequence is under investigation.

T.C.P.144

INHIBITION OF HIV-1 REPRODUCTION BY SYNTHETIC PEPTIDES FROM REGION OF ENV,GAG,VPU PROTEINS SIMILAR TO CELL RECEPTORS CD-4 AND HLA-DR.

V.Blinov,A.Pokrovsky,O.Yastrebova,S.Chaplygina,L.Sandahchiev, A.Kozhich*,B.Koshalkov*,L.Chykin*,V.Ivanov*.
All-Union Research Institute of Molecular Biology, Koltsovo, *Shemyakin Institute of Bioorganic Chemistry,Moscow,USSR

The CD4 antigen was identified as an essential component of the cell surface receptor for HIV-1,and it interacts with HLA antigen of 11 class.Regions of viral proteins similar to receptors CD-4 and HLA-DR were localisated in gp41,gag,vpu and gp120 respectivetily.

Selected peptides, g90(547-559env)-SGIVQQQNNLLRA;g92(557-573env)-RAIEAQQHLLQLTVWG;g93(43-53vpu)-DRLIERAEDSG;g94(92-107gag)-IEIKDTKEALDKIEEE;g96(419-430env)-CRIKQIINMWQE;g97(428-439env)-MWQKVGKAMYAPP;g98(68-81vpu)-VEMGHAPWDVDDL were synthesized and used in follow up study of HIV-1 infected cells. Cells were examined at various times after HIV-1 infection by measuring of reverse transcriptase(RT) activity, virus antigens expression and viral RNA by hibridisation method.

It was found that peptides g92,g98 could be induced significantly inhibition of HIV reproduction,when there are added every day at the concentration 100 ng/ml.The g96 and g 97 peptides were inhibited RT activity more than twice only at early stage of virus infection.Additionly,the neutralizing activity of sera obtained to these peptides was studied.

These studies indicated that peptides from viral proteins similar to CD-4 receptor has suppressive effect on virus reproduction.

T.C.P.145

5'-PHOSPHONATE DERIVATIVES OF 3'-AZIDO-2',3'-DIDEOXYNUCLEOSIDES: SYNTHESIS AND INHIBITION OF HIV REPRODUCTION IN CELL CULTURES

Tarussova, Natalya; Kukhanova, M.; Khorlin,A.; Krayevsky,A.; Galegov,G.; Kornilova,M. ; Nosik,D. ;Uryvayev,L. ; Beabealashvilli,R .V.Engelhardt Institute of Molecular Biology, the USSR Academy of Sciences, Moscow; D.Ivanovskii Institute of Virology and National Cardiology Research Center, the USSR Academy of Medical Sciences, Moscow, USSR

Objective. A group of new 5'-phosphonate of 3'-azido-2',3'-dideoxynucleosides was studied in cell cultures, infected by HIV. Methods. Synthesis of 5'-hydrophosphonates, 5'-methylenephosphonate and 5'-methylphosphonate of 3'-azido-2',3'-dideoxynucleosides was ellaborated. The activity of these compounds on HIV reproduction in H9/IIIB and MT4 cell cultures was evaluated by reverse transcriptase activity and using immunofluorescent and colorimetric analysis.
Results. 5'-Methylene- and 5'-hydrophosphonates of 3'-azido-2',3' dideoxythymidine revealed the activity close to that of 3'-azido-2',3'-dideoxythymidine (AzT) at the supression of HIV-1 reproduction, whereas their toxicity was significantly lower both in HIV-infected and noninfected cells. 5'-Hydrophosphonates of AzA and AzG were essentially more active than initial nucleosides, their toxicity being as well significantly lower. Some metabolic data for 5'-phosphonates in cells were investigated. Conclusion. The new group of highly active anti-HIV compounds was found.

T.C.P.146

REDUCED IN VITRO GROWTH AND DIFFERENTIATION OF MONOCYTES FROM PATIENTS WITH HIV INFECTION

Müller, Fredrik; Rollag, H.; Gaudernack, G. & Frøland, S.S.
University of Oslo, The National Hospital, Rikshospitalet, Oslo, Norway

Methods. Monocytes (Mo) from patients with HIV (CDC II/III, n=36; AIDS, n=15), 14 HIV seroneg. homosexual men and 58 blood donors were cultured for 1 and 10 days. The number of Mo/Mφ(macrophages), protein and cell differentiation were determined,the last by immunocytochemical staining with monocl.antibodies (Mabs) against two differentiation antigens. The in vitro growth of Mo was also measured in (a) 8 AIDS patients receiving zidovudine,(b) 12 patients where Mo were cultured with Mo/Mφ supernatant from normal blood donors, and (c) 6 patients where Mo were cultured with M-CSF (Mφ Colony Stim. Factor).
Results. On day 10, the number of Mφ and cell protein were reduced in CDC II/III and even more in AIDS. Depressed in vitro growth correlated with reduced function of the bone marrow (BM) assessed as low numbers of erythrocytes (r=0.45,p=0.003), leukocytes (r=0.36,p=0.01) and thrombocytes (r=0.41, p=0.007) in peripheral blood.On day 10, HIV+ Mφ were significantly less differentiated than control Mφ. Of the patients treated with zidovudine, 3 out of 8 showed a transient improvement of in vitro growth during the first 2-3 months. Mo/Mφ supernatants from healthy donors as well as M-CSF did partially reconstitute the in vitro growth defect in the majority of patients tested. Conclusion: Decreased Mo in vitro growth and differentiation are seen in most patients with HIV infection.This may be due to lack of cytokines as suggested by the reconstitution experiments. The correlation of decreased Mo in vitro growth and low numbers of blood cells might also suggest that defects in BM precursor cells are operative.Another mechanism may be HIV replication in Mo.

T.C.P.147

THE ROLE OF INTERLEUKIN-4 (IL-4) IN AIDS.

Pavri Khorshed.
Project Director, ICMR Centre for AIDS Research & Control, Pune. India.

Objective :To present a model explaining pathogenesis of AIDS.
Methods : A literature survey has been made of molecular to epidemiologic aspects of AIDS and animal retroviruses, and of cytokines. Relevant information is presented to explain the pathogenesis.
Results : This model is based on interaction between latent HIV lurking as intracisternal A particles (IAP), other infectious agents which induce IL-4 and act as cofactors,and also, host's genetic factors. Many human CD4+ T helper cells simultaneously secrete IL-2, IL-4, and IFN-γ. IL-4 stimulates B cells to polyclonal activation and also enhances expression of HLA-DR which is spatially associated with CD23, low avidity Fc receptor for IgE (Fc$_\epsilon$R2). N linked glycosylation site on HIV gp120 which binds with CD4 is also associated with HLA-DR. Transactivation of latent HIV occurs via enhancer element present in the IAP-LTR. IgE antibody formation is genetically controlled and regulated by IFN-γ. Addition of IL-4 to mouse cells compensates for the genetic defect of a nonresponder mouse strain. Similarly, HIV-infected poor responders may overcome the defect if repeatedly triggered by IL-4 inducing cofactors. Antibodies to gp120 mimic autoantibodies to HLA-DR, which compromise effective functions of antigen presenting cells and the T$_h$-B cell interaction. IL-4 also appears to be the HTLV-induced growth factor reported to be responsible for Kaposi's Sarcoma seen in AIDS patients.
Conclusions : The model explains the depletion of T$_h$ cells in AIDS and also why some individuals develop full-blown AIDS faster than others.

T.C.P.148

FURTHER INVESTIGATIONS ON A LABORATORY MODEL BASED ON HIV-1 SPECIFIC CYTOTOXIC T LYMPHOCYTES

Arida, Elie. Natl. Research Center, Cairo, Egypt.

The author had previously reported on the development of HIV-1 specific cytotoxic T cells, (Arida,E., 6th Internat. Cong. of Immunol., July 6-11,1986, Toronto, Canada, Abstracts:3.55.15, p. 460. Arida, E., 7th Internat. Cong. of Virology, August 9-14,1987, Edmonton, Canada, Abstracts: R38.6). In the present work, the characteristics of these cells after 6 month of propagation were investigated under several experimental conditions. These included IL-2, T cell mitogens, parasitic antigens, certain cations, cheliating agents, etc,...The cells retained their response to HIV-1 specific cytotoxic effect (SCE), even after 6 month of propagation. They proliferated freely in absence of IL-2, T cell mitogens & parasitic antigens which stimulate T cells. HIV-1 SCE was maintained by the cells only up to 10 month of propagation & was furtherly retained by treatment with Cd, Zn & Cu++ ions, but not with Cu+, Fe or Co. Cheliating agents interfered with the above cation effect. Cheliating agents (including Ca agents) interfered with HIV-1 SCE when the whole virus was used but not with its related genetic materials. These results indicate genome integration of an HIV-1 provirus & its associated influence on T cell response. The value of these cells as lab. models for immunologic tolerance is evident.

T.C.P.149

MONOCLONAL ANTIBODIES RAISED TO RECOMBINANT HIV-1 GAG-PROTEINS CAN IDENTIFY IMMUNODOMINANT B CELL EPITOPES IN AIDS PATIENTS.

Eric Saman, P. De Baetselier*, R. De Leys, C. Wauters and H. Van Heuverswyn.
Innogenetics N.V., Antwerpen, Belgium. *University of Brussels, Belgium.

Objective: The ability of serum antibodies from AIDS-patients to compete with the binding of mouse anti-p24 monoclonal antibodies to the E. coli produced antigen, was investigated.
Methods: Microwell plates coated with E. coli produced purified p24 HIV-1 antigen, were incubated with serial dilutions of sera from AIDS-patients, followed by incubation with the monoclonal Ab, which was then detected with an anti-mouse HRPO conjugate. Inhibition of monoclonal binding was scored as a decrease of the signal, relative to the unblocked reaction. Microwells coated with monoclonal were incubated with culture supernatant from several HIV-1 producing cell-lines to investigate the binding of native viral antigen. Captured antigen was detected with an anti-HIV human IgG conjugate.
Results: Five anti-p24 and two anti-p17 mouse monoclonal antibodies were investigated. For two anti-p24 monoclonals, a variable degree of interference from a panel of 50 human anti-HIV sera was observed. The corresponding epitopes are thus immunogenic in most HIV-1 patients. However, one of these monoclonals does not recognize the antigen from viral lysates. This implies that the epitope is not acceesible in mildly denatured p24 protein. This points to the identification of epitopes exposed only after denaturation (presentation) of the viral antigen.
Conclusion: Mouse monoclonal antibodies to denatured recombinant HIV-antigen are able to identify epitopes recognized in HIV-infected humans, but not accessible in the native antigen.

T.C.P.150

HUMAN MONOCLONAL ANTIBODIES TO HIV

D.Berzow 1), M.Bögel 1), C.G.Meyer 1), R.Grunow 2) ,
R.von Baehr 2), H.Schmitz 1)
1)Bernhard -Nocht -Institute for Tropical Medicine, Department of Virology, Hamburg, BRD
2)Charite', Department of Immunology, Berlin , DDR

Objective : The production of human monoclonal antibodies to HIV and the evaluation of role of antibodies in HIV-infections.
Methods : The heteromyeloma cell line CB F7 (Grunow et al, J.Immunol.Methods, 106, 1988, 257-265) was used for cell fusions with peripheral blood lymphocytes from HIV-positive blood donors. Clones were screened for specific and continuous antibody production. Supernatants from stable hybridomas were tested in specific neutralisation and cytotoxicity assays.
Results: In 20 fusion experiments a fusion frequency of 0.6×10^{-5} and a specific fusion frequency of 0.8×10^{-7} was obtained.
16 clones were recloned, all were directed against envelope glycoproteins of HIV; five were specific for gp 41 and eleven for gp 120. One clone against gp 120 produced continuously for the last three month. Neutralisation and cytotoxicity assays are in progress.
Conclusion : We have established a method allowing the production of specific monoclonal antibody producing hybridomas against different epitopes of HIV. This will enable us to investigate the correlation of neutralising or cytotoxic effects of monoclonal antibodies with the type of epitopes recognized in order to get more information concerning the interaction of HIV and antibody response.

AEROSOL DELIVERY OF PENTAMIDINE TO THE DEEP LUNG : A MODEL OF ISOTOPIC QUANTITATION IN BABOONS.

P. DIOT*, C. JUBAULT*, J.L. BAULIEU*, P. CHOUTET***, E. LEMARIE**, A. LE PAPE*
* Lab. de Biophysique Cellulaire, CNRS-Faculté de Médecine, TOURS ; ** Service de Pneumologie, and *** Service de Médecine A, Centre Hospitalier Universitaire, TOURS, France.

The intraveinous treatment of Pneumocystis Carinii pneumonia with Pentamidine in AIDS patients is known to induce frequently adverse reactions. Aerosol administration was proved to be avoid from these toxic effects, but the best aerosolization conditions remain as yet to be defined. In this goal, we have developped a scintigraphic model to assess the deep lung accessibility of the drug. After an in vivo control of quality of isotopic labelling, the preparation was administered to 4 unanesthetized baboons as an aerosol containing 200 mg Pentamidine labelled with 370 MBq 99m Technetium. For each baboon, 2 types of aerosolizers were compared ; a TV6000 ultrasound SIEMENS (Germany) device and a compressed air Venticis ORIS (France) nebulizer. Acquisitions and processing of dynamic scintigraphies (160 images of 1 min) were performed using a PHO GAMMA CAMERA SEARLE (USA) connected to a TIM 512 computer (France). The Pentamidine lung burden was assessed based on the comparison of the lung activity to the counts obtained in a thorax like phantom containing 37 MBq 99m Tc. Pentamidine was about equally distributed between the 2 lungs and so, a total lung burden could be assessed. Using the ultrasound system, the lung burden was very low (0.06 mg i.e. 0.03 % from the initial dose opposite to the gastric delivering (0.22 mg i.e. 0.1 %). On the contrary, when using the Venticis device, the Pentamidine mass delivered to the deep lung was 1.52 mg i.e. 0.7 % with a neglectible clearance during the time course of the study (gastric delivery was 0.257 mg i.e. 0.128 %).

So, these results obtained in the baboon point out the crucial ro'e of aerosolization method for an efficient delivery of Pentamidine to the deep lung. Radiolabeling of Pentamidine offers a convenient and precise way to quantify the effective pulmonary dose and so to optimize the aerosol conditions in AIDS patients. Based on this strategy, clinical studies are currently in progress.

W.C.P.3

PERSISTENT HIV2 INFECTION OF RHESUS MACAQUE, BABOON AND MANGABEYS

Nicol, Isabelle*; Flaminio-Zola, G* , Dubouch, P** ; Desportes, I*; Bernard, J*; Zagury, D*
*Université P. et M. Curie, Paris, France, **C.N.R.S., Villejuif, France

Objective. Establishment of persistent HIV2 infection in monkeys

Methods. Six monkeys of three different species (Mangabey, Macaque and Baboon) have been infected with HIV2 NIH-DZ using intraperitoneal or intraveinous injections of cell-free HIV2 or autologous HIV2 infected cells with no prior immunostimulation. Viral expression was demonstrated by reverse transcriptase activity measured in cells after coculture with human peripheral blood lymphocytes, by electron microscopy and by southern blot analysis. Serum was analysed by Western-Blot, ELISA (detection of antigen and antibody) and neutralization assay carried out using immunofluorescence techniques

Results. The six inoculated animals seroconverted in the first month after inoculation and remained persistently infected up to two years as demonstrated by RT activity, IFA, EM. We also observed integrated proviral DNA by genomic analysis in the six tested samples. No sign of immunodeficiency disease has so far been observed

Conclusion. This is the first report of experimental HIV2 infection of mangabeys. *(Cercocebus sp.)*

W.C.P.5

CD8+ AND CD4+ RESPONSES TO HIV-1 ANTIGENS IN MICE IMMUNIZED WITH VACCINIA VIRUS (VV) RECOMBINANTS.

Michel, Frédérique*, Hoffenbach, A.*, Chenciner, N.*, Kieny, M.P.°, Rautmann, G.°, Guy, B.°, Lecaud, G.°, Kaczorek, M.°°, Girard, M.°°, Wain-Hobson, S.* and Plata, F.*
*Institut Pasteur, Paris ; °Transgène S.A., Strasbourg ; °°Pasteur Vaccins, Marnes-la-Coquette - France

Objective : To study the HIV-specific cytotoxic and proliferative responses in mice immunized with VV recombinants expressing HIV-1 envelope protein or internal gag protein or non structural nef protein.

Methods : BALB/c mice were inoculated intravenously with VV recombinants or wild-type VV. Cytotoxicity assays were performed with syngeneic P815 target cells transfected with the HIV-1 env, gag or nef gene. Proliferative responses were performed using recombinant envelope gp160, gag p25, gag p18, nef p27 proteins and synthetic peptides.

Results : 1) HIV-specific CD8+ T lymphocytes were detected with P815-env-LAV, P815-gag-LAV or P815-nef-LAV target cells after in vitro interleukin-2 expansion of spleen cells. 2) A bulk memory and specific CD4+ proliferative response was observed against gp160, p25 and p27 proteins. In contrast, p18 was weakly immunogenic in mice. 3) Antigen-specific T cell lines were obtained by repeated stimulation with recombinant proteins. The proliferative and cytolytic capacities of these lines were studied.

Conclusions : Thus internal gag protein and non-structural nef protein of HIV-1 can induce cell-mediated immune responses in mice. Our murine model also permits to evaluate the immunogenic power of different HIV proteins.

W.C.P.2

SIV$_{AGM}$ AND SIV$_{MND}$ MIGHT BE NONPATHOGENIC IN VIVO

Yoshihiro Ohta*; Ishikawa,K.*;Tsujimoto,H.*;Mukai,R.**;Honjo,S.**;Hayami,M.*** et al.
*Inst. Med. Sci.,Tokyo Univ.,**Natl. Inst. Health,***Inst. Virus Res., Japan.

Objective. To see infectability and pathogenicity of SIV$_{AGM}$ and SIV$_{MND}$ in various species of monkeys.

Methods. Three African green monkeys and three cynomolgus monkeys were inoculated with SIV$_{AGM}$[TYO-1] derived from a healthy African green monkey. Besides, four cynomolgus monkeys, three cotton-top tamarins and a common marmoset were inoculated with SIV$_{MND}$[GB-1] derived from a healthy mandrill. Virus reisolation and antibody detection were carried out in these animals. Hematological and immunological analyses including ConA response assay and the level of biochemical parameters in plasma were examined. Organs removed at necropsy (SIV$_{AGM}$-infected group:42 weeks p.i.,SIV$_{MND}$-infected group:20 weeks p.i.) were histopathologically examined.

Results. All animals inoculated with SIV$_{AGM}$ seroconverted within 2 weeks, and virus was recovered 2 to 42 weeks p.i. Cynomolgus monkeys and cotton-top tamarins inoculated with SIV$_{MND}$ seroconverted within 2 weeks, and virus was recovered 2 to 9 weeks p.i. in cotton-top tamarins. Animals infected with SIV$_{AGM}$ developed slight swelling of superficial lymph nodes 12 weeks p.i. and virus was reisolated from spleen and lymph nodes in 5 of 6 monkeys at the necropsy. But no noticeable changes in immuno-hematological analyses and histopathologic observation at necropsy were detected in these infected monkeys.

Conclusion. SIV$_{AGM}$ might not induce overt AIDS in its original host as well as in cynomolgus monkeys, and SIV$_{MND}$ is also considered to be nonpathogenic.

W.C.P.4

A RABBIT MODEL OF HTLV-I INFECTION: SEROCONVERSION PATTERNS AND DETECTION OF VIRUS BY PCR.

Lairmore, Michael*, Cockerell, CG**, Hartley, TM*, De, BK*, Rovnak, J**, and Miyoshi, I***, *Centers For Disease Control, Atlanta, GA, USA, **Colorado State U., Ft. Collins, CO, USA, ***Kochi Medical School, Kochi, Japan.

Objective: Determine the antibody reactivity and virus distribution of rabbits persistently infected with HTLV-I. Methods: Neonatal and weanling rabbits were inoculated with HTLV-I infected cells by IP, IV or IC routes. Antibody status were assessed by IFA, WIB, and RIP assays. HTLV-I sequences were examined by Southern blot and PCR from PBMC and tissues. Results: All HTLV-I-inoculated neonatal rabbits which survived beyond 3 wks seroconverted to HTLV-I, while controls remained antibody negative. Antibody patterns included early (3 to 5 wks pi) and persistent (42-90 wks pi) reactivity to p24, p55 and gp68, while reactivity to p19 was variable. IFA titers peaked between 1:160 and 1:320, but decrease after 14 wks pi. Among virus-infected rabbits (neonatal group-killed 70-94 wks pi) HTLV-I pol and gag sequences were detected by PCR from PBMC [3/3 (#test/ #positive), liver (1/1), and mesenteric lymph node (2/2). Extracts of spleen, bone marrow, and cecal lymphoid tissue of 2 infected rabbits and PBMC from a control rabbit were negative by PCR. PBMC from infected and control rabbits were negative by direct Southern blot. No clinicopathologic alterations could be attributed to HTLV-I infection. Conclusions: HTLV-I infected rabbits, similar to humans, develop early and persistent antibody to HTLV-I gag p24 and env 68 and contain low numbers of HTLV-I positive leukocytes. HTLV-I infected rabbits are useful to study persistent HTLV-I infections in humans.

W.C.P.6

MACROPHAGES FROM LP-BM5 INFECTED MICE INDUCE MURINE AIDS.

Janis K. Lazdins*, R.M. Cozens* and J.D. Gangemi**
*Research Laboratories, Pharmaceutical Division, CIBA-GEIGY Ltd., CH-4002, Basel, Switzerland. **Dept. of Microbiology and Immunology, USC-School of Medicine, Columbia, SC., 29208, USA.

The LP-BM5 murine leukemia virus induces an immunodeficiency syndrome in mice (MAIDS) similar to human AIDS. To further validate this model we examined the role of macrophages as reservoirs of LP-BM5 virus. Four week old C57Bl/6 mice were infected i.p. with 0.5ml of supernatant from continuously infected SC-1 cells (TC2110); 37 days later disease was confirmed by enlarged spleens and by ConA unresponsive lymphocytes. Peritoneal exudate cells were isolated (no differences from controls were observed). Macrophages (MØ) were purified by adherence, scraped off and resuspended in PBS (10^6/ml). Splenocyte suspensions were prepared (10^6/ml). This material (1ml) and the corresponding controls were injected i.p. in normal C57Bl/6 mice. After 45 days enlarged spleens were detected only in the MØ infected group, by 65 days splenomegaly was also detected in the splenocyte infected group. At this point the animals were sacrificed, spleen weight and ConA response assessed (MTT method).

i.p. injection with:	Spleen wt. (mg)	ConA response (stimulation factor)
MØ Control	74±13	6
MØ Infected	2039±760	0
Splen. Cont.	78±12	4
Splen. Infec.	1998±300	0

These results indicate that macrophages are an important retroviral reservoir in the LP-BM5 MAIDS model similar to human AIDS.

W.C.P.7 INTERCOMPARISON OF DIFFERENT SIV ISOLATES IN RHESUS AND CYNOMOLGUS MACAQUES

Kitchin, Peter[1]; Cranage, M.P.[2]; Stott, E.J.[1]; and Baskerville, A.[2].
[1]WHO AIDS Collaborating Centre, NIBSC, Potters Bar, UK and [2]Division of Pathology, PHLS CAMR, Salisbury, UK.

Objective Comparison of different SIV isolates in macaques.
Methods Six different isolates of SIV (SIVmac251 low passage (LP) and high passage (HP); SIVcyn186 (LP) from Dr R Desrosiers; SIVagm Tyol and 2 (HP) from Dr Hayami; SIVsm7 from Dr P Fultz). Animals were injected i.v. with virus and then bled at 2-4 week intervals. All sera were analysed by synthetic peptide ELISA, Western blotting and by RIPA.
Results All animals receiving SIVmac251 (LP), SIVcyn186 and SIVsm7 produced antibodies to the gag, pol and env viral proteins. Those receiving the SIVagm strains or SIVmac (HP) did not seroconvert. The two animals receiving SIVmac251 (LP) (rhesus 32H and cynomolgus 705B) were studied in greater detail. The rhesus 32H produced a persistent antibody response and virus was routinely re-isolated from this animal. In contrast, the cynomolgus 705B, produced only a weak antibody response, and died from a wasting syndrome 305 days p.i. The authenticity of the 32H and 705B SIV re-isolates was confirmed by PCR and sequence analysis.
Conclusion SIVmac251(LP) is pathogenic for cynomolgus macaques and can be used as an animal disease model for human AIDS.

W.C.P.8 STRAIN SPECIFICITY OF LYMPHOCYTE PROLIFERATIVE RESPONSES IN EXPERIMENTAL ANIMALS IMMUNIZED WITH RECOMBINANT HIV-1 gp120 ANTIGENS.

Wentworth, Peggy, Doe,B., Haigwood,N., Shuster,J., Scandella,C., and Steimer,K. Chiron Corporation, Emeryville, California, USA.

Objective: To determine if the helper T-cell responses to recombinant gp120 polypeptides are directed against conserved and/or variable regions.
Methods: The following non-glycosylated, denatured HIV gp120 proteins were produced in yeast: full-length gp120 from the HIV-SF2, HIV-HTLVIIIB and HIV-Zr6 isolates; N-terminal (aa 26-277) and C-terminal (aa 274-510) halves of HIV-SF2 gp120; HIV-SF2 gp120 with the third hypervariable domain (aa 300-332) deleted; and HIV-SF2 gp120 with all five hypervariable regions (aa 131-134, 156-198, 300-332, 388-414, and 457-463) deleted. In mammalian cells, glycosylated, native HIV-SF2 gp120 has been produced. Lymphocytes from animals immunized with purified gp120 antigens were tested in vitro for proliferative responses to the immunizing antigen and other gp120 polypeptides.
Results: Lymphocytes from various immunized animals have shown that both type and group-specific helper T cell responses are elicited, that conserved T-cell epitopes exist outside the major hypervariable domains of gp120, and that T-cell responses are directed against epitopes that map to both halves of gp120. Furthermore, lymphocytes from animals immunized with non-glycosylated gp120 clearly respond in vitro to the glycosylated molecule from the same isolate. However, preliminary results suggest that glycosylation may influence the strain specificity of T-cell responses.
Conclusions: These studies point out the complexity of the T-cell responses to HIV-1 gp120. Both type and group-specific responses have been observed, and there may be differences in the responses to glycosylated and non-glycosylated versions of the same molecule.

W.C.P.9 THE SIGNIFICANCE OF PREMATURE STOP CODONS IN ENV OF SIV

Kodama, T., Naidu, Y., Wooley, Dawn P., Kestler, H., Li, Y., and Desrosiers, R.
New England Regional Primate Research Center, Harvard Medical School, Southborough, MA USA

Objective. To determine the size requirements of the envelope transmembrane protein (TMP) of SIV for replication in cultured cells and in vivo.
Methods. DNA sequences of the TMP region in infectious molecular clones of SIVmac were determined. Virus was produced in cultured cells by transfection of cloned DNA using DEAE-Dextran and analysed by western blot.
Results. SIVmac251 and SIVmac142 infectious molecular clones have premature stop codons that yield virus with short (28-30K) TMP. SIVmac239 cloned virus does not have a premature stop codon; transfection of HUT-78 cells with this clone initially yields virus with 41K TMP. However, in HUT-78 cells there is strong selective pressure for a short 28-30K TMP. Upon growth of cloned SIVmac239 in HUT78 cells, virus with 41K TMP gradually disappears coincident with the emergence of virus with 28-30K TMP which eventually predominates. Cloned virus with 41K TMP grows very well upon serial passage in normal macaque lymphocytes and maintains a 41K TMP in these cells. Virus recovered from an infected macaque using normal macaque lymphocytes yielded virus with 41K TMP.
Conclusion. The natural form of the TMP in SIV appears to be the full length 41K version. Shorter forms of TMP in SIV result from growing the virus in unnatural cell types such as HUT-78 and MT4, human tumor T cell lines. Differences observed in the different cell types may be used to shed light on the role of the carboxy terminal portion of TMP either in virus entry or in the assembly and budding process.

W.C.P.10 CONSTRUCTION AND CHARACTERIZATION OF RECOMBINANT VACCINIA VIRUS EXPRESSING THE ENVELOPE GLYCOPROTEINS OF SIVmne.

Hu, Shiu-Lok ; Travis, B.M. ; Abrams, K. ; Chinn, J. ; Morton, W.R. ; and Benveniste, R. . Oncogen, Seattle, WA, USA; Regional Primate Research Center, Seattle, WA, USA; National Cancer Institute, Frederick, MD, USA.

Objective: To determine the biochemical and immunogenic properties of SIVmne envelope glycoproteins expressed by recombinant vaccinia virus.
Methods: A recombinant vaccinia virus has been constructed that contains the entire env gene of SIVmne. The biosynthesis and the processing of the recombinant-made env proteins were analysed by serological assays. The ability of these glycoproteins to induce syncytium formation was tested in HeLa-CD4$^+$ cells. The recombinant virus was inoculated into rodents and macaques for immunogenicity studies.
Results: Three glycoproteins were detected by SIV-positive macaque sera in cells infected with the recombinant vaccinia virus. By their mobility in SDS-PAGE and their immunoreactivity, these proteins correspond to the precursor gp160 and the mature forms gp130 and gp32. HeLa-CD4$^+$ cells infected with vaccinia-SIVenv recombinant virus did not form syncytia as readily as those infected with an analogous recombinant virus expressing the env glycoproteins of HIV-1. Results of immunogenicity studies will be presented.
Conclusion: The envelope glycoproteins of SIVmne are expressed and processed in recombinant vaccinia virus infected cells. Unlike their HIV counterparts, recombinant-made SIVmne glycoproteins do not mediate syncytia formation in CD4$^+$ cells efficiently. This recombinant will be useful for the study of the immunogenic properties of SIV envelope antigens.

W.C.P.11 FIV-AIDS MODEL FOR TESTING NOVEL VACCINE APPROACHES FOR HUMAN AIDS

Yamamoto, Janet K. and Okuda, T.
Department of Medicine, School of Veterinary Medicine, University of California, Davis, California, USA.

Objective. Heterologous feline T lymphocytes infected with feline immunodeficiency virus (FIV) were used as an inactivated whole cell vaccine against feline AIDS.
Methods. Hallmark of FIV-FAIDS is immunosuppression resulting in increased susceptibility of the infected cats to secondary infections and death resulting from these secondary infections. In this study FIV-AIDS was used as a small animal model of human AIDS to test novel vaccine approaches. Infected cell vaccine consisted of adjuvant and FIV-infected feline T lymphocytes ($1x10^7$ cells/specific pathogen free cat) inactivated prior to the study with gluteraldehyde. The adjuvant used in the vaccines was thronyl-muramyl dipeptide. Uninfected cell vaccine consisted of adjuvant and uninfected feline T lymphocytes (inactivated).
Results. No virus was isolated from any of the cats prior to virus challenge. By the 4th vaccination, all 3 cats with infected cell vaccine developed antibodies to viral p17, p28, gp40, p52, and p54, and by this time, 2/3 of these cats developed antibodies to envelope gp58 except for one cat which developed after the 8th (the last) vaccination. The results below were obtained from cats monitored over 17 weeks post-challenge (wk p.c.) with live virus.

Vaccine Type	1st Virus Isolation	No. of Cats Alive
Infected Cell + Adjuvant	4 wk p.c.	3/3 (100%)
Uninfected Cell + Adjuvant	1 wk p.c.	2/2 (100%)
Adjuvant	1 wk p.c.	0/1 (0%)
None	1 wk p.c.	3/6 (50%)

Conclusion. Cats with infected cell vaccine developed antibodies to majority of viral proteins detectable by immunoblot and in these cats, the onset of the cell-associated viremia was delayed by 3 weeks. Heterologous cell vaccines appeared to decrease the mortality of the cats challenged with live FIV. Additional monitoring of these cats should determine the efficacy of this vaccine over prolonged period of time.

W.C.P.12 EVOLUTION OF THE ENVELOPE GENE OF SIVmac-BK28

Edmonson, Paul F.*, Murphey-Corb, M.**, Hirsch, V.***, and Mullins, J.I.*. *Harvard School of Public Health, Boston, MA **Delta Regional Primate Research Center, Covington, LA ***Present address: NIH/NIAID, Twin Brook, MD., U.S.A.

Objective. Relative to HIV-1, many SIV isolates encode truncated Transmembrane Proteins (TMPs), as a result of a stop codon in the TMP gene. Previous work by our laboratory has demonstrated that this stop codon is required for the production of infectious virus when the BK28 molecular clone of SIV$_{mac}$ is cultured in HUT78 cells. Consequently we decided to address the role of genomic evolution in the pathogenesis of SIV infections, initially by assessing changes occurring in the vicinity of the TMP stop codon. Here we report on changes within the SIV$_{BK28}$ TMP gene in viruses replicating in cultured cells and in infected macaques.
Methods. 4 rhesus were inoculated with a combination of 2 derivatives of SIV$_{BK28}$: a stop codon-less construct, and a spontaneous "revertant" containing a stop codon, that arose during in vitro growth. A portion of the TMP gene was amplified directly from infected HUT78 cells and infected rhesus lymphocytes using the Polymerase Chain Reaction, and amplified products were cloned into pUC18 and their DNA sequences determined.
Results. These viruses showed no increase in pathogenicity over parental BK28, all 4 remain healthy at 17 months p.i. TMP genes recovered from an animal 10 months p.i. were all distinct from the virus inoculum. Eleven of 15 clones carried a 12bp deletion centered over the TMP stop codon permitting production of an extended, gp41 TMP. The other 4 clones carried a different 12 bp deletion which recreated a stop codon and permitting a truncated gp32 to be produced. The TMP genes of virus derived from this animal following propagation in H9 cells were exclusively of the latter type, indicating strong in vitro selection.
Conclusion. An extraordinarily high degree of mutation and selection occurs within the region surrounding the TMP stop codon of SIV$_{BK28}$. Whether the biological basis for selection for such mutations reflects requirements for glycoprotein structure or for the utilization of alternate splice acceptor sites for viral regulatory genes (see abstract by Viglianti and Mullins) remains unclear.

W.C.P.13 ISOLATION AND PRELIMINARY CHARACTERIZATION OF A NEUROTROPIC STRAIN OF FELINE LEUKEMIA VIRUS

Peter W Gasper, LR Whalen*, J Overbaugh*, DW Wheeler*, SW Dow, ML Poss.
Pathology Dept., *Anatomy and Neurobiology Dept., Colorado State University, *Microbiology Dept., School of Medicine, University of Washington, Seattle. U.S.A.

SIGNIFICANCE: We have isolated a strain of feline leukemia virus (FeLV-1390)which induced significant delays in motor nerve conduction velocities in 3 of 3 experimentally infected specific pathogen free (SPF) cats within 7 months post inoculation. This isolate may lead to development of a feline model of AIDS peripheral neuropathies to be utilized in future testing of therapies for AIDS.
METHODS: Bone marrow and CSF were harvested from 3 cats exhibiting neurologic abnormalities. All 3 cats were FeLV positive and FIV negative. Two cats were naturally infected. One cat (#1390) was experimentally infected with molecularly cloned (mc) FeLV-3281 2 years before developing neurological problems. All samples were cocultured with feline fibroblasts (AH927 cells). Six SPF cats were inoculated (intracisternally and intraperitoneally), 2 each, with cell free supernatants containing 10^5 ffu of the 3 potentially neurotropic strains of FeLV. Four additional SPF cats were similarly inoculated; 2 with 10^5 ffu of minimally pathogenic mc FeLV-61E, and 2 with virus-free medium. The cats were housed under barrier conditions in two gang cages (5 cats/cage). Electrophysiology was performed and the cats were euthanized between 6 and 7 months post inoculation.
RESULTS: All of the FeLV-inoculated cats became FeLV positive approximately 3 weeks post inoculation. One of the medium-inoculated cats tested FeLV positive 9 weeks post inoculation. We assume this cat (#1970) contracted FeLV-1390 horizontally from the infected cats with which it was housed. A virus restriction pattern similar to mc FeLV-3281 was identified by Southern blot analysis of the FeLV genomes present in cat # 1970 and the 2 cats inoculated with FeLV-1390. The motor nerve conduction velocities of #1970 and the 2 cats infected with FeLV-1390 were significantly decreased when compared to the velocities of uninfected age-matched control cats and cats infected with mc FeLV-61E.
CONCLUSION: FeLV-1390 induced significant delays in motor nerve conduction velocities analogous to HIV and/or HTLV-1 peripheral nervous system lesions.

W.C.P.14 IN SITU IMMUNOASSAYING SUGGESTS CENTRAL NEUROENDOCRINE INVOLVEMENT IN INFANT FELINE AIDS (FAIDS)

Torres-Aniel, Manuel J.*; Ray, B.*; Elliott, S.C.* and Tshikuka, J.G.*
*Univ. of Missouri at Columbia, USA.

Objective. To emulate in FAIDS, the human AIDS (HAIDS) demonstration that HIV infects and affects the CNS. In FeLV+FAIDS this link was, up until our work, conspicuously missing.
Methods. The samples were brain extracts from case vs. control infant kittens (N=29) with FAIDS induced with intracerebral injection of FeLV "A" (ATCC-717). The viral assays were based on commercial reagents: polyclonal anti-FeLV virion (Antibodies Inc., Davis, CA USA) or monoclonal anti FeLV gsa p27 (CITE™-AgriTech Systems, Portland, ME USA) antibodies. The results were confirmed with a commercial ELISA (LEUKOASSAY™F or II, Pittman Moore, Washington Cross, NJ USA). Endocrine affection was shown by a heterologous rabbit anti-rat growth hormone (GH) titration in hypophyses by immunostaining. The difference in GH in the adenopituicytes between controls and FAIDS cases was significant ($p<0.01$).
Results. This study further corroborates our preliminary reports on FeLV in CNS. Pituitary GH diminution coincided with growth impairment in the form of failure-to-thrive and an ensuing fatal wasting syndrome undistinguishable from our own results with rabies [1].
Conclusion: FAIDS in kittens, as a model for HAIDS in children, strongly suggests a neuroendocrine participation that, at least in part, may explain the immunodeficiency [1].
(The kind support of the manufacturers of commercial FeLV and RV bio-technology diagnostics, as mentioned, is kindly appreciated).

[1]. Torres-Anjel et al. Failure to thrive, wasting syndrome and immunodeficiency in rabies: a hypophyseal/hypothalamic/thymic axis effect of rabies virus. Rev Infect Dis. 1988:10 (Suppl.4):S710-25.

W.C.P.15 IN VIVO ANALYSIS OF THE MINIMAL INFECTIOUS DOSE OF AN ACUTELY LETHAL POOL OF SIV (SIV/SMM/PBJ-14)

McClure, Harold M., Anderson, D.C., Ansari, A. and Fultz, P.
Yerkes Regional Primate Research Center and Department of Pathology, Emory University, Atlanta, GA, U.S.A.

Objective. To determine the minimal infectious (lethal) dose of an acutely lethal virus pool of SIV derived from a chronically infected macaque.
Methods. Six groups of 2 pig-tailed macaques were inoculated IV with 10-fold serial dilutions of the PBj-14 isolate, or doses ranging from 10^4-0.1 TCID$_{50}$.
Results. All animals given 10 TCID$_{50}$ or greater became infected and developed acute clinical disease. Although there was no evidence the two recipients of 1 TCID$_{50}$ became infected, one animal that received 0.1 TCID$_{50}$ was infected and at 6 weeks P.I. had reduced numbers of CD4$^+$ cells that decreased progressively until death 9 months P.I. In the other animals, disease onset ranged from day 7 (10^4 TCID) to day 12 (10 TCID) P.I., with death occurring from day 8-16. One animal survived the acute disease but showed a progressive decrease in CD4$^+$ cells and died 7 months P.I., with emaciation, oroesophageal candidiasis, lymphadenopathy, splenomegaly, lymphopenia and a CD4/CD8 ratio of 0.16.
Conclusion. The lowest dilution (10^{-3} or 10 TCID$_{50}$) of a pool of the PBj-14 isolate of SIV/SMM to infect all animals also resulted in death of both animals within 16 days, supporting the contention that PBj-14 is the sole agent responsible for the acute lethal disease. There was a correlation between dose and onset of disease and death. Two longer term survivors showed decreasing CD4$^+$ cells, weight loss, lymphadenopathy, lymphopenia and opportunistic infections. Disease in these animals appeared to correlate with a marked reduction in CD8$^+$ cells. (Supported by NIH grant RR00165).

W.C.P.16 HIV-1 INFECTION IN A CONTINUOUS RABBIT MACROPHAGE LINE

Henrietta Kulaga*, David Recker**, Ellen Gugel** and T.J. Kindt**.
NIMH, St. Elizabeth's Hospital, Washington, D. C. **Laboratory of Immunogenetics, NIAID, NIH, Bethesda, MD 20892.

Objective: To characterize HIV-1 infection in a continuous rabbit macrophage line.

Methods: The rabbit cell line, 6083, an SV40-transformed macrophage was infected with HIV-1. Infection was monitored using standard methodologies including RT activity and the presence of p24Ag in cell-free supernatants, indirect immunofluorescence, electron microscopy, detection of viral nucleic acids and passage of infectious virus to a number of indicator cell lines.

Results: 6083 was shown to be permissive to HIV-1 infection by all parameters assessed with the exception that no RT activity was seen in supernatants from infected cells. Presence of viral proteins were evidenced by p24 Ag capture, indirect immunofluorescence and Western blot analysis. In addition to the presence of HIV-1 nucleic acids, electron microscopy indicated production of mature lentivirus particles in a fashion morphologically similar to that seen in human macrophages and different from T-cell infection. Although virus positive by the preceding assays, cell free supernatants from HIV-1 infected 6083 cultures gave negative RT results. Supernatants derived from uninfected 6083 cultures were also shown to abrogate RT activity in known positive samples. It was shown that the lack of RT activity was not due to a direct inhibitor of the enzyme; both infected and uninfected 6083 cells produce a factor which interfere with the assay at the level of the nucleic acid template.

Conclusions: 6083 supported productive HIV-1 infection which is similar to that seen in human macrophages. As is the case for human cell lines of this lineage, measurement of RT activity cannot be used as an accurate parameter of infection in rabbit macrophages.

W.C.P.17 REGULATION OF THE VISNA VIRUS LTR IN MACROPHAGES INVOLVES CELLULAR FACTORS WHICH BIND SEQUENCES CONTAINING AP-1 SITES

Gabuzda, Dana H.; Hess, J.; dela Torre, A.; Small, J.; Clements, J.
The Johns Hopkins Medical Institutions, Baltimore, Maryland, USA

Objective. To identify sequences in the visna virus long terminal repeat involved in the developmental regulation of gene expression in macrophages.
Methods. Deletion and linker-scanning mutants, gel shift assays, and DNase I footprinting were used to study regulation of the visna virus LTR in the U937 monocytic cell line. Similar experiments using human primary macrophages are in progress.
Results. Sequences in the visna virus LTR that are involved in the regulation of visna virus gene expression in U937 cells were identified, including a region containing an AP-1 binding site which is critical for basal activity and phorbol ester-inducible gene expression. Nuclear extracts from uninduced and phorbol ester-induced U937 cells protected the same sequences from DNase I digestion; however, protection of the AP-1 site was significantly increased in nuclear extracts from induced cells. A DNase I-protected region from -87 to -81 contains the sequence TTTTTTG, which is similar to DNase I-protected sequences in the HIV and HTLV-I LTRs.
Conclusion. Our data supports a model in which one or more of the proteins which interact with AP-1 sites may be involved in the developmental regulation of visna virus gene expression in macrophages. Understanding the molecular events which relate macrophage differentiation to the regulation of viral gene expression may provide insights into mechanisms controlling viral gene expression that may be relevant to disease pathogenesis.

W.C.P.18 INFECTION WITH SIMIAN IMMUNODEFICIENCY VIRUS (SIV) VIA CONJUNCTIVAL AND ORAL MUCOSAE IN A NEWBORN RHESUS MACAQUE

Jennings, Myra*; Lerche, N.*; Tillery, S.*; Yee, J.*; Antipa, L.* and Chesney, P.**. *Univ.of California-Davis, Davis, California, USA, **Univ. of Tennessee Memphis, TN, USA.

Objective. To determine if SIV can be transmitted post-natally via the mucous membranes in the newborn rhesus macaque and to determine if transmission can occur from infected infant to mother during the neonatal period as a result of close contact.
Methods. SIV was dropped on the conjunctival and oral mucosae of a newborn rhesus macaque at 0 and 93 days post-natally. Following exposure to virus, the infant was kept with the mother and both were tested for SIV infection.
Results. SIV was isolated from the peripheral blood mononuclear cells (PBMC) of the infant 22 days after the second exposure to virus and at all other sampling times thereafter. The animal died of cachexia and pneumonia 2 months after virus was detected. Generalized lymphoid depletion and interstitial pneumonia were noted at necropsy. The mother remains healthy, SIV antibody and virus negative.
Conclusion. SIV can be transmitted via conjunctival and oral mucosae in a newborn macaque. Despite intimate contact with the infected infant, the mother remains healthy and uninfected.

W.C.P.19 THERAPY OF MAIDS (LP-BM5 INFECTION OF C57BL-6 MICE) WITH DIETHYLDITHIOCARBAMATE (DTC).

Funk, C.*; Mosier, D.**; Petersen, E*; and Hersh, E.*.
*University of Arizona, Tucson, Arizona, 85724, USA, ** Medical Biology Institute, La Jolla, California, 92037 USA.

Objective. To determine the dose and time relationships in treating LP-BM5 with DTC. We have previously reported that DTC administered from the time of virus innoculation can prolong survival in mice and partially prevent both lymphadenopathy and hypergammaglobulinemia. We now report that there is a strict dose and time relationship for efficacy of this agent in the model.
Methods. Animals were innoculated with an amount of virus that results in 100% mortality by 26 weeks. DTC treatment was given 5 days per week IP. Node size, spleen weight, serum IgM and survival were measured.
Results. Dosage efficacy was 600 mg/kg (the maximally tolerated dose) >400 mg/kg >200 mg/kg; all given IP 5 days/wk. At each dosage level, therapy started 2 weeks after virus innoculation was more effective that dosing starting on the day of virus innoculation. If therapy was started as late as 10 weeks after virus (3 weeks before animals begin to die) lymphadenopathy was abrogated and mortality prevented. If therapy was stopped, disease progression resumed.
Conclusion. Determining the mechanism of action of DTC and the use of cogeners of DTC may lead to new approaches to AIDS therapy.

W.C.P.20 MOLECULAR CONSTRUCTION OF A CHIMERIC HIV/Akv MuLV PROVIRAL CLONE.

Pedroza-Martins Livia*, Chenciner, N.*, Cheynier, R.*, Delassus, S.*, Perez, L.*, Plata, F.* and Wain-Hobson, S.*
*Institut Pasteur, Paris - France ; *Actual address : Mount Sinai Medical Center, Fl - USA

Objective : to develop a chimeric HIV potentially infectious for murine cells, that could lead to a convenient animal model for AIDS research.
Methods : A molecular clone of HIV was constructed by substituting the 1.6 kb fragment of the HIV env gene coding for gp120 by a 1.8 kb fragment from the Akv MuLV env gene coding for gp70 and the extracellular part of p15E. The resulting virus thus has a hybrid MuLV/HIV env gene. The steps in construction were : 1) Akv MuLV and HIV env genes were subcloned in phage M13, and convenient restriction sites were introduced by site-directed mutagenesis. 2) The HIV env fragment was replaced by the Akv MuLV env fragment. 3) The hybrid env gene was reintroduced into a HIV proviral clone, and proviral DNA was transfected into human and mouse cells. 4) Virus production and infectivity were determined by reverse transcriptase assays and other virological techniques.
Results : A chimeric molecular clone of a MuLV/HIV provirus was obtained and characterized by restriction fragment analysis and DNA sequencing. The genetic sequences for HIV gp120 and vpu have been deleted. Production of virus particles with reverse transcriptase activity by human and mouse cells following transfection of chimeric proviral DNA is under study.

W.C.P.21 PATHOLOGY OF FELINE IMMUNODEFICIENCY VIRUS (FIV) INFECTION

Konno, Akihiro; Ishida, T.; Matsumura, S.; Washizu, T.; Tomoda, I.
Nippon Veterinary and Zootechnical College, Tokyo, Japan.

Objective. To study pathologic changes associated with feline immunodeficiency virus (FIV) infection.
Methods. A total of 15 cats naturally infected with FIV were examined pathologically. The cases included 2 PGL, 1 ARC, and 12 AIDS stages, and they were all examined post mortem.
Results. The lymph nodes of 2 PGL cats (one euthanatized and one died of renal disease) showed reactive changes with follicular hyperplasia. The latter had marked mast cell infiltration in the medulla. The nodes of the ARC cat died of pyothorax showed both hyperplastic changes and moderate dysplastic lesions in different nodes. All of the 12 AIDS cases had dysplastic nodes characterized by follicular atrophy, paracortical cell depletion, and fibrosis. Three cases showed extensive necrosis due to cryptococcal infection. Two AIDS cases had hypoplastic bone marrow, while the rest 8 AIDS cases showed hyperplasia with emperipolesis of megakaryocytes in 1 case. Seven AIDS cases had chronic stomatitis. Two were ulcerative stomatitis, and the rest were characterized by chronic active inflammation with extensive cellular proliferation. Many had bacterial or cryptococcal infection. Eight AIDS cases had primary hepatic lesions and 1 had metastatic mammary adenocarcinoma. Serous hepatitis, with accompanying peliosis hepatis in 1 case, was seen in 4 AIDS cases. These lesions were characterized by accumulation of proteineous material in the Disse's space compressing the hepatic cord. Other 4 cases showed cholangiohepatitis of unknown origin. Although cases with clinical renal failure were excluded from this study, many had moderate to intermediate changes. Glomerulonephritis and chronic interstitial nephritis was seen in 7 and and 4 cases, respectively. There were no P. carinii pneumonia cases. Interstitial pneumonia was seen in 4 cases, and bacterial lober pneumonia was found in 1 case. The cases studied here had no clinical evidence of neurologic disturbances, and showed no major histologic changes in the brain except for mild cell infiltration in some cases.
Conclusion. The lymphoid lesions suggested presence of the similar immunologic alterations as in HIV infection. The manifestations of AIDS phase disorders were, however, in part different from those in the human patients.

W.C.P.22 UN MODELE EXPERIMENTAL DU SIDA CHEZ LA SOURIS, QUI ELICITE DES INFECTIONS ET DES ANGIOSARCOMES (AS)

Dubé, Manon; Madarnas, p.[2], Rola-Pleszczynski, M.[1] et Nigam, V.N.[1] - [1]Département d'Anatomie et de biologie cellulaire et [2] département de Pathologie, Faculté de médecine, Université de Sherbrooke, CANADA

Les souris transgéniques contenant de l'ADN proviral du virus HIV (Science 242, 1665, 1988), les souris C57 BL/6 infectées par le mélange du virus murin de la leucémie LP-BM5 (J. Exp. Med. 161, 766, 1985) et les cellules cultivées du Sarcome de Kaposi (SK) injectées aux souris nues (Science 242, 430, 1988) sont quelques uns des modèles du SIDA infectieux ou du SK. Aucun ne combine les deux comme dans le cas des hommes homo et bisexuels avec le SIDA. Nous avons démontré auparavant, que les souris CD1 à laquelle on donne du diméthylhydrazine de façon hebdomadaire pour 25 semaines et ensuite le difluorométhylornithine, ont des tumeurs colorectales, une grande incidence d'angiosarcomes et des infections qui causent leur mort.

Le but de ce projet est de décrire les évènements qui suivent dans le développement des infections et des angiosarcomes. Les souris CD1 ont reçu 20 mg/kg de DMH une fois par semaine, de façon sous-cutanée. Un groupe de 5 de ces animaux et une souris normale du même âge sont sacrifiés à toutes les 2 semaines et nous déterminons les sous-population de cellules T spléniques et périphériques, les réponses mitogéniques aux LPS et à la concanavalin A et la production d'anticorps 5 jours après une injection i.p. de globules rouges de mouton (PFC). Jusqu'à présent, après 23 semaines, la réponse (PFC) et l'activité mitogénique aux LPS démontre une diminution chez les animaux traités au DMH, de même que des changements néoplasiques précoces dans le côlon. Les sous-populations de cellules T demeurent inchangées. Ces résultats semblent indiquer qu'une immunosuppression se développera et mènera au développement d'angiosarcomes et d'infections

W.C.P.23 ADAPTATION OF HUMAN IMMUNODEFICIENCY VIRUS SEROLOGIC TESTS TO THE SIMIAN IMMUNODEFICIENCY VIRUS MODEL.

Yee, JoAnn L., Jennings, Myra B., Lerche, Nicholas W., and Carlson, James R.
University of California, Davis, USA.

Objective. Simian Immunodeficiency Virus (SIV) in monkeys has emerged as an important model system for studying the Human Immunodeficiency Virus (HIV). HIV and SIV are antigenically similar so that commercially available HIV II antibody and HIV I antigen reagents can be used for the SIV model system.
Methods. We evaluated the use of HIV II enzyme immunoassay (EIA) and Western blot (WB) (Genetic Systems Corp., Seattle, WA and E.I. DuPont, Inc., Wilmington, DE) for the detection of SIV antibodies in sera from captive and wild caught monkeys. In addition, HIV I antigen EIA (Abbott Laboratories, No. Chicago, IL; Coulter Immunology, Hialeah FL; E.I. DuPont, Inc., Wilmington DE; Genetic Systems Corp., Seattle, WA) were evaluated for the detection of SIV antigen in monkey sera and peripheral blood mononuclear cell culture supernatants.
Results. HIV II antibody EIA and WB equalled the performance of WB using SIV antigen. The HIV I antigen EIA was as sensitive as reverse transcriptase for detection of SIV antigen in culture supernatant. The HIV I antigen assay detected SIV antigen in serum at reduced sensitivity when compared to HIV I.
Conclusion. Commercially available HIV reagents are suitable for serological studies in the SIV model system.

W.C.P.24 ENHANCEMENT OF ANTIVIRAL THERAPY IN HIV INFECTION USING BLOOD-BRAIN BARRIER (BBB) MODIFICATION WITH INSULIN: ANIMAL DATA AND CLINICAL CONSIDERATIONS

Ayre, Steven G.; Skaletski, B.; Hosnain, A.D. The Chicago Medical School, North Chicago, Illinois, USA.

Objective: HIV infection of the CNS is resistant to treatment with the nucleoside-analog antiviral compounds (AZT, ribavirin) due to poor BBB penetration of these agents. Left untreated, intra-CNS HIV will cause persistence of systemic HIV infection by acting as a source of continuous reinfection for extra-CNS tissues. Modification of the BBB using insulin can increase the passage of antiviral drugs into the substance of the brain, and allow for effective antiviral therapy in the HIV-infected host.
Methods: Using the tissue sampling technique of Oldendorf, the brain-uptake index (BUI) of AZT was measured in 6-8 week old Sprague-Dawley male white rats, both with and without pretreatment of the rats with doses of insulin.
Results: Compared to an antipyrine standard, the BUI of AZT was found to be 5.4 ± 0.8 ($\bar{X}\pm$S.D., n=13, range 4.4-6.6). Pretreatment of animals with 1.0 unit of regular insulin, 10 minutes before the AZT injection, resulted in a statistically significant ($p < 0.01$) increase in the BUI of AZT (7.8 ± 1.3, $\bar{X}\pm$S.D., n=7, range 6.8-10.6).
Conclusion: A combination of insulin and AZT increased the BBB passage of the antiviral drug in rat brain. Preliminary experience using this treatment strategy in conjunction with ribavirin in two human subjects with symptomatic HIV infection (CDC Group IV-A and IV-B) has produced long-term remissions in both cases (27 and 31 months). An FDA approved clinical trial using insulin in combination with AZT is currently in progress.

W.C.P.25 LACK OF VERTICAL TRANSMISSION OF SIVagm IN A BREEDING COLONY OF CERCOPITHECUS AETHIOPS

Birgit B. Kvinesdal*; L.S. Bruun* and C.H. Nielsen*
*Statens Seruminstitut, Copenhagen, Denmark.

Objective. To investigate the occurrence of vertical transmission of simian immunodeficiency virus (SIVagm) in a breeding colony of *C. aethiops* by testing for SIVagm antibodies.
Material and Methods. Wild-caught *C.aethiops* imported from Ethiopia and offspring from these born at Statens Seruminstitut. The breeding colony was founded with 21 female and 8 male monkeys imported in the period 1976 to 1988. Serum samples from the 29 imported and from 70 colony born monkeys were examined by an indirect immunofluorescence test for antibodies against SIVagm.
Results. Live offspring were produced in the colony by 14 of the 21 imported females. Six of the 14 female breeders were found SIVagm antibody positive and gave later on birth to 26 young. From 22 of the young first time bleedings were obtained around 6 months of age or later. None were found SIVagm antibody positive. From 12 of the 22 young another sample collected 1-4 years later was also SIVagm antibody negative. Samples from the remaining 4 young, taken at age 3 months or less, were SIVagm antibody positive. In 2 of the 4 SIVagm antibodies could not be demonstrated in samples drawn around 6 months of age; one died; the fourth remains to be tested, when 6 months old.
Conclusion. In *C.aethiops* vertical transmission of SIVagm is rare if at all occurring. Presumably maternally acquired SIVagm antibodies disappear within the first 6 months of life.

W.C.P.26 EXPERIMENTAL HIV-2 INFECTION OF OLD WORLD MONKEYS

Castro, Blesila A.; Eichberg, J.W.*; Lerche, N.W.** and Levy, J.A.
Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143, *Southwest Foundation for Biomedical Research, San Antonio, TX 78228, **California Primate Center, Davis, CA 95616 USA

Objective: To develop a model of HIV infection in Old World monkeys.
Methods: Peripheral blood mononuclear cells (PBMC) from baboons and rhesus macaques were screened for susceptibility to infection with four HIV-2 isolates from the Ivory Coast. Infected cells were cocultivated with uninfected PHA-stimulated monkey PBMC of the same species or with human PBMC. Culture supernatants were assayed for HIV reverse transcriptase activity. Animals whose cells showed high levels of virus replication and cytopathology *in vitro* were inoculated with the strains producing these results. Serum antibody, lymphoid cell counts, and virus production from the animals'PBMC were monitored monthly.
Results: All four HIV-2 strains tested were infectious for baboon and macaque cells, but some could be detected only upon addition of human PBMC. One isolate (UC-2) grew well in baboon cells. Two isolates (UC-2 and UC-7) replicated well in most macaque PBMC. All isolates generally showed enhanced growth in macaque and human PBMC cultures. UC-2 and UC-3 were most cytopathic for both types of animal cells, and were used for inoculation of the baboons and macaques. We have recovered HIV from PBMC of the infected macaques and seroconversion has been observed in the baboons. Serologic, immunologic and virus isolation data on the infected animals will be presented.
Conclusion: HIV-2 isolates show differential growth in non-human primate cells. Productive infection of primates with HIV-2 has been achieved after preselection of susceptible animals and specific virus strains.

W.C.P.27 MECHANISM OF DOWNREGULATION OF CD4 EXPRESSION BY PLASTIC ADHERENT HUMAN MACROPHAGES IN VITRO

Mathijs J.M., Kazazi F., Malafiej P., Foley P., and Cunningham A.L. Virology and Infectious Diseases Units, Westmead Hospital, NHMRC Special Unit in AIDS Virology Research, Sydney, Australia.

The 57kd non-polymorphic CD4 molecule acts as the major receptor for HIV on both CD4+ lymphocytes and blood monocytes. We have further investigated the regulation and function of monocyte/macrophage CD4 *in vitro*. Previously we found that the expression of CD4 antigen on the surface of Leu M3 positive human blood monocytes was variable with 65% - 90% of cells being positive by dual staining flow cytometry. When monocytes adhered to plastic, which activates macrophages, loss of CD4 expression was observed by Flow cytometry and immunofluorescence between by 3-5 days but the proportion of adherent cells expressing Leu M3 and OKM5 did not decrease. Monocytes cultured on teflon remained CD4 positive. Surface iodination of blood monocytes and plastic adherent macrophages followed by immunoprecipitation with anti-CD4 monoclonal antibodies also demonstrated a marked reduction in membrane CD4 expression by these macrophages. However CD4 mRNA levels quantitated by Northern blotting and total cellular CD4 protein levels (as demonstrated by immunoprecipitation) remained constant throughout the five day period, suggesting a selective loss of CD4 from the membrane, probably by endocytic cycling. Phorbol esters (PMA,PDB) also reduced the proportion of CD4 expressing monocytes from 90% to 8%. However no differences were observed in binding of radiolabelled PDB and PMA to blood monocytes and macrophages. Whether CD4 is is phosphorylated during downregulation and the effect of protein kinase C inhibitors on this phenomenon is under investigation. Activation of macrophages by lipopolysaccharide and interferon gamma had no effect on CD4 expression by monocytes maintained in teflon vessels, nor did other cytokines (M-CSF,GM-CSF,IL1,IL2,TGF-β TNFα).

W.C.P.28 CULTURE REQUIREMENTS FOR HIV-1 ISOLATION FROM INFECTED CHIMPANZEES

Piazza, Paolo A.; Kobb, K.E. and Eichberg, J.W.
Southwest Foundation for Biomedical Research, San Antonio, Texas, U.S.A.

Objective. To optimize conditions for the isolation of HIV-1 from peripheral blood lymphocytes (PBL) of infected chimpanzees.
Methods. PBL were obtained 4-9 times over a 4-month period from nine HIV-1 seropositive chimpanzees. Parallel cultures were generated each time following three protocols: (1) nonstimulated chimpanzee PBL were cocultivated with phytohemagglutinin (PHA) activated human PBL as indicator cells; (2) chimpanzee cells were PHA activated and then cocultured with human indicator cells; and (3) chimpanzee PHA activated PBL were cultured without human cells. All cultures were maintained in the presence of interleukin-2 and DEAE-dextran for 28 days and monitored weekly for production of HIV-1 in supernatants by antigen capture assay.
Results. HIV-1 isolation was successful in five out of nine chimpanzees by any protocol employed. In two of these five animals, HIV-1 could be isolated only by protocol (1) and (2); in one animal only by protocol (3), and by all three protocols in the other two animals.
Conclusions. The difficulty in isolating HIV-1 from chimpanzees is confirmed, suggesting a low level of virus integration in PBL; in some animals a clear preference for one culture condition is evident; an adverse effect of human PBL on the production of virus in one chimpanzee also indicates that requirements for virus isolation can differ dramatically between these animals and humans.

W.C.P.29 PRIMARY RETROVIRAL INFECTION VERSUS CHRONIC VIREMIA: DIFFERENTIAL RESPONSE TO THERAPY.

Ruprecht, Ruth M. *, **; Mullaney, S.*; and Andersen, J.*.
*Dana-Farber Cancer Institute, Boston, Massachusetts, USA, **Harvard Medical School, Boston, Massachusetts, USA.

Objective. To compare the therapeutic efficacy of candidate antiretroviral agents administered to animals exposed *de novo* to pathogenic retroviruses with that of therapy given to chronically viremic animals.
Methods. Adult female BALB/c mice were inoculated at time 0 with Rauscher Murine Leukemia Virus (RLV), a virus complex consisting of a lymphotropic replication-competent helper virus as well as a replication-defective spleen-focus forming virus. For post-exposure treatment, therapy was started 4 hr after virus inoculation and continued for 20 d. The animals were sacrificed and analyzed for RLV-induced splenomegaly and viremia. Therapy of chronically viremic animals was initiated only at 2 weeks after virus exposure and was continued throughout the animals' life span. Survival was analyzed by Kaplan Meier plots. 3'-azido-3'-deoxythymidine (AZT or Zidovudine), recombinant human interferonαA/D (rHuIFNαA/D), and castanospermine were administered as above.
Results. AZT and castanospermine were active in primary infection as well as in chronic viremia. In contrast, rHuIFNαA/D was able to suppress virus-induced splenomegaly by 94%, but was completely inactive in chronically infected animals: Median survival of animals treated with rHuIFNαA/D starting 14 d after virus exposure was identical to that of untreated control animals (6.7 vs 6.9 weeks, $p = 0.34$).
Conclusion. Biologically, the chronically viremic state differs significantly from primary retroviral exposure, as judged by the differential response to therapy. Evaluation of antiretroviral therapy should be carefully designed to differentiate between these situations.

W.C.P.30 PATHOLOGY OF EARLY LESIONS IN SIV ENCEPHALITIS

Sharer, Leroy*, Epstein, L.*, Michaels, J.*, Murphey-Corb, M.**, Martin, L.**, and Baskin, G.**
*New Jersey Medical School, Newark, NJ, USA, and **Delta Regional Primate Research Center, Covington, LA, USA.

Objective. To study central nervous system lesions early in the course of infection with simian immunodeficiency virus (SIV).
Methods. Twenty juvenile rhesus macaques were inoculated i.v. with SIV/Delta B670, with 4 controls. Four animals each were sacrificed at 2, 4, 8, and 24 weeks post inoculation; four became moribund and were sacrificed at 10, 11½, 20 and 23 weeks. Histologic preparations of fixed brain tissue were examined, using also immunoperoxidase for glial fibrillary acidic protein (GFAP) and for SIV antigen, employing a rabbit polyclonal antiserum.
Results. At 2 weeks there were lymphocyte infiltrates in choroid plexus (CP) and leptomeninges (LM), with a few perivascular lymphocytes in brain parenchyma; rare inflammatory cells in CP contained SIV antigen. At 4 weeks, macrophage infiltrates with positive antigen staining were observed around parenchymal vessels in 2 animals; lymphocyte infiltrates persisted in CP and LM, with rare multinucleated giant cells (MGC) in LM. The most severe lesions were observed in the moribund animals at 10 and 11½ weeks, with brain perivascular macrophage infiltrates, with MGC and karyorrhexis. Lesions were less marked in the 24 week animals. No animal exhibited myelin pallor or an excess of GFAP white matter staining, compared with controls.
Conclusions. SIV causes inflammation in LM and CP early in the course of disease, with infection occurring in the cerebrospinal fluid (CSF) compartment before it is seen in brain. The earliest occurrence of brain SIV antigen coincides with the appearance of perivascular macrophages.

W.C.P.31

HIV-1 ANTIGENEMIA IN ATHYMIC "NUDE" MICE

Wetherall, Neal T. and Andrea Eiring

Department Of Pathology, Vanderbilt University Medical Center, Nashville, TN., U.S.A. 37232-2561

Objective. Several small animal models of HIV infection have been proposed. We have developed a simple means to support the replication of HIV-1 which can produce large populations of infected mice for therapy screening and host-virus interactions.

Methods. Nude mice (3-4 wks old) were exposed to 600 R's of ^{137}Cs irradiation and inoculated with 1 x 10^7 HIV-1 infected CEM cells. The animals were followed daily for weight gain and tumor progression. Groups of 6 animals were exsangiunated at 8 intervals over a 9 week period and necropsies were performed.

Results. Plasma p24 antigen was detected at day 3 and rose over 9 weeks (>2200 pg/ml). Where possible, plasma antigen was neutralized with human antisera to HIV-1. The infected mice did not exhibit any weight loss, but a highly significant difference was seen in tumor progression when compared to controls. Using immunohistochemistry, sheep raised polyclonal antibodies to viral p24 and gp120 detected HIV proteins within tumor cells and mouse splenic macrophages. Electron microscopy revealed rare intracellular lentivirus particles in the CEM cells.

Conclusion. These findings suggest that the nude mouse transplanted with a well characterized HIV permissive cell line should be useful for many immunological and antiviral studies.

"This work is supported by the U.S. Army Medical Research and Development Command Under Contract No. DAMD 17-88-C-8071."

W.C.P.32

LANGERHANS CELLS IN RHESUS MONKEY ORAL MUCOSA BEFORE AND AFTER INFECTION WITH SIMIAN RETROVIRUS SEROTYPE 1 (SRV-1).

Hammerle,Christoph*; Schiødt,M.*+; Lackner,A.≠; Armitage*,G.; Wirthlin,W.*; MacPhail,L.*; Daniels,T.* and Greenspan,J.*. *Oral AIDS Center, University of California, San Francisco, ≠California Primate Research Center, Davis, California, +University Hosp. and Royal Dental College, Copenhagen, Denmark.

Objective. To study the influence of experimental SRV-1 infection on the number of Langerhans cells (LC) expressing characteristic antigens in oral mucosa of rhesus monkeys.

Methods. Ten monkeys were intravenously inoculated with SRV-1, and two animals were mock-inoculated. Status of infection was assessed by serology and virus culture from peripheral blood lymphocytes. Biopsies were taken from gingiva and cheek pouch before and 4 months after infection. Frozen sections were reacted with monoclonal antibodies (Leu-6, HLA-DR) and visualized by the immunoperoxidase technique. LC were counted in 3 sections of each specimen using each antibody, and the mean number of LC per surface mm was calculated. The examiner was blinded as to the identity of the slides.

Results. All animals except for the controls were viremic at 1 week after inoculation. The number of LC in oral epithelium did not differ significantly between the experimental and control groups at time 0 and time 4 months. The table shows LC of the experimental group.

LC in oral mucosa	Gingiva		Cheek pouch	
(no./surface mm)	Leu-6	HLA-DR	Leu-6	HLA-DR
Before infection	10.4	9.1	9.9	9.4
	P>0.05	P>0.05	P>0.05	P>0.05
4 months after infection	7.2	7.0	12.4	10.1

Conclusion. We have previously shown that SRV-1 commonly infects oral mucosal LC in rhesus monkeys. However, 4 months after SRV-1 infection the number of LCs in the oral mucosa did not change significantly.

Supp.by NIH PO1-DE07946, Danish Med.Res.Council (#12-8499,12-8465), and AIDS Fondet.

W.C.P.33

INOCULATION OF BABOONS AND MACAQUES WITH VIRUS PRODUCED FROM THE SIV/Mne MOLECULAR CLONE

Morton, W.R.[1]; Kuller, L.[1]; Clark, E.A.[1,2]; Gale, M.J.[1]; Foy, K.[1], Overbaugh, J.[1,2]; Katze, M.G.[1,2]; Heidecker, G.[3]; Benveniste, R.E.[3].
[1]Regional Primate Research Center, University of Washington, Seattle, Washington, [2]Dept. Microbiology, University of Washington, [3]Lab of Viral Carcinogenesis, NCI, Frederick Cancer Research Center, Frederick, Maryland, U.S.A.

A full length molecular clone of SIV/Mne (CL8) was shown to be infectious in vitro by transfecting the DNA into Hut 78 cells and showing the presence of reverse transcriptase activity. 1x10^{3} TCID of virus from transfected cells was inoculated into two pigtailed macaques and two baboons intravenously on November 5, 1987. The four inoculated animals, as well as the two control animals, were examined at regular intervals for the presence of antibodies to SIV/Mne and for the presence of virus in PBL and plasma. Animals were also monitored for changes in their clinical and immunological status. Both baboons developed marked peripheral lymphadenopathy by two weeks post-inoculation, but no virus was isolated from their PBL. One of the baboons died at 33 weeks post-inoculation with anemia and a wasting syndrome similar to that seen in macaques inoculated with SIV/Mne. Attempts at virus isolation were negative at the time of death. To determine if cells containing SIV/Mne viral genomes were present in this baboon's lymphocytes or monocytes, DNA was extracted from the spleen and lymph nodes. Utilizing the polymerase chain reaction (PCR) technique, we were unable to detect SIV/Mne sequences in either the spleen or lymph node tissues of this animal. The pigtailed macaques developed peripheral lymphadenopathy four and eight weeks post-inoculation, along with an erythematous rash on the lower abdominal and inguinal areas. Both animals seroconverted and virus could be isolated at various times post-inoculation. At 64 weeks post-inoculation, both animals remain in apparent good health. However, one has exhibited a steady decrease in CD4^{+} cells since November 1988, along with thrombocytopenia and absolute lymphocyte depletion, which in previous transmission studies, were forerunners of clinical disease.

W.C.P.34

MUTATIONAL ANALYSIS OF THE CYTOPLASMIC DOMAIN OF SIV TRANSMEMBRANE PROTEIN

L. Chakrabarti, P. Tiollais, and P. Sonigo. Institut Pasteur, Paris., FRANCE

Objective: To examine the role of the cytoplasmic domain of the transmembrane protein in absence of the *env* in-frame stop codon found in SIV infectious clones.

Methods: Oligonucleotide-directed mutagenesis was used to replace the in-frame stop codon by a glutamine codon. Point mutations and deletions were introduced in the *env* C-terminal domain in clones both with and without the in-frame stop codon. Phenotypes of different mutants were evaluated for virus production following transfection of SW480 cells and for infectivity in HUT78 cells.

Results: SIV in wich the in-frame stop codon was replaced by a glutamine codon infected HUT78 cells with delayed kinetics. Reversion of the slow phenotype frequently occured. Revertants having recovered a stop codon 3' to the original mutation were characterized. Deletions and termination 3' to the in-frame stop codon did not modify SIV infectivity. In contrast, mutants harbouring both the mutation of the in-frame stop codon and a deletion or a termination in the cytoplasmic domain-coding region were non infectious.

Conclusion: The *env* C-terminal domain is not necessary for *in vitro* replication. However, fusion of this domain to SIV transmembrane protein leads to a reduced infectivity. This negative effect is counterselected in vitro but may correspond to a function controlling the rate of spread of the virus in the natural host.

W.C.P.35

INFECTION OF RHESUS MACAQUES WITH MOLECULARLY CLONED HIV-2

Franchini, Genoveffa*, Markham, P.D.**, Gard, E.**, Robert-Guroff, M.*, Gallo, R.C., Wong-Staal, F., et al.
*National Cancer Institute, Bethesda, MD 20892, **Bionetics Research, Inc. Rockville, MD. U.S.A.

Objective: To develop a suitable animal model system to study infectivity and cytopathogenicity of HIV and to study viral genetic variation in vivo.

Methods: Rhesus macaques inoculated iv with molecularly cloned isolates of HIV-2 were monitored for humoral and cellular immune response, infectious virus, and physical and hematologic abnormalities. Selected viral genes from viruses reisolated from infected animals were analyzed by cloning and sequencing.

Results: Six of eight inoculated animals became persistently infected, e.g., recoverable virus, detectable genomic DNA, and/or persistent immune response. Some physical abnormalities began to appear in some animals with 6 months post-infection. Genetic changes occurring in vivo were found in virus reisolated 5 months post-infection.

Conclusion: Rhesus macaques are a useful infectivity model for HIV-2. Use of infectious molecularly cloned virus isolates provide a homogenous basis for evaluation of the generation of genomic variants in vivo.

W.C.P.36

CLINICAL AND IMMUNOLOGIC STAGING OF FELINE IMMUNODEFICIENCY VIRUS (FIV)INFECTION

Ishida, Takuo; Taniguchi, A.; Washizu, T.; Kobayashi, T.; Tomoda, I.
Nippon Veterinary and Zootechnical College, Tokyo, Japan.

Objective. To elucidate the relationship between disease progress and immunologic alteration in feline immunodeficiency virus (FIV) infection.

Methods. The initial phase of FIV infection was studied in 5 SPF cats infected with FIV. 700 naturally-infected cats were classified into clinical stage groups using criteria modified from those for HIV patients. Lymphocyte blastogenesis was monitored by glucose consumption assay using Con A as the mitogen.

Results. The experimental infection in SPF cats revealed development of the initial acute phase of FIV disease, with a 10- to 40-week duration, characterized by lymphadenopathy, cyclic neutrophilia, fever, and chronic diarrhea. Among 700 naturally infected cats, there were 41 cats (5.9%) under 2 years of age showing the acute phase signs. In the experimental infection, the acute phase was followed by the asymptomatic carrier (AC) phase. On the basis of the serologic survey, 12.4% of clinically healthy cats had antibody to FIV with positive virus isolation, and 10.8% of the 700 antibody positive cats were asymptomatic. The mean age of the asymptomatic carriers (4.2 yrs) was smaller than that of severely ill FIV infected cats. A majority (537/700=76.7%) of the infected cats, with a mean age of 5.3 yrs, were showing a combination of chronic illness such as PGL, weight loss, diarrhea, respiratory disease, stomatitis, and skin disease, and these signs were similar to those in human ARC. More severe illness, characterized by the presence of anemia, emaciation, opportunistic infections and/or malignancies in addition to ARC signs, were seen in 6.9% of the 700 infected cats. These cats were diagnosed AIDS, and 75% (36/48) of the cases died within 6 months. The stimulation indices (SI) of Con A blastogenesis of the FIV infected cats were 48.40±4.33, 21.30±13.00, and 5.18±4.90, in AC, ARC, AIDS, respectively. These figures were all significantly lower (p<0.01) than that of uninfected healthy cats (SI=91.60±5.13). The differences between AC and ARC (p<0.01), and ARC and AIDS (p<0.05) were also significant.

Conclusion. The disease progress in FIV infection parallels with the decrease in the immunologic responsiveness. The clear distinction between each clinical phases makes this cat system excellent for the animal model of AIDS.

W.C.P.37

ESTABLISHMENT OF FIV-PRODUCING CELL LINES FROM FIV SEROPOSITIVE CATS

Satoshi,Nagata*; Chiba,J.*;Kikuta,K.*;Tamura,S.*; Kobayashi,T.**; Ishida,T.** and Kurata,T.*.
* NIH Japan,Tokyo,Japan. ** Nippon Veterinary and Zootechnical college,Tokyo,Japan.

Objective. To establish feline T-cell lines that continuously produce FIV in the culture. Methods. Peripheral blood mononuclear cells from 4 feline immunodeficiency virus (FIV)-seropositive and feline leukemia virus (FeLV)-negative cats were stimulated with concanavalin A (Con A) for 3-5 days and maintained with recombinant human interleukin-2 (IL-2). Results. After 4-6 weeks. reverse transcriptase activity was detected in 2 out of 4 culture supernatants without marked cytopathic effects. One of the two lines (named GA-3) was further characterized. FIV antigens were detected and identified in GA-3 cells by indirect immunofluorescence and western blot analyses. FeLV and feline syncytium-forming virus were not detected by the same methods. The virus produced by GA-3 cells failed to replicate in feline fibroblastic cell, CRFK. GA-3 cells required IL-2 and interestingly re-stimulation with Con A every 2-3 weeks for their growth. GA-3 cells have been growing and releasing FIV for more than 2 months so far. Infectivity and pathogenicity of the FIV produced by GA-3 are under investigation. Conclusion. IL-2 dependent feline lymphoid cell lines which continuously produce FIV were established.

W.C.P.38

SEROLOGIC VARIABLES AT DIAGNOSIS WITH KAPOSI'S SARCOMA(KS): PREDICTORS OF SHORTENED SURVIVAL.

Cusick, P.S.**; Moss, A.*; Bacchetti, P.*; Winger, E.***; Edison*, R.J.; Feigal, D.W.;Volberding, P.A.*; * et al. *AIDS Activities Division, San Francisco General Hospital,Univ of California,SF;** Univ of Massachusetts, Worcester, MA; ***Immunodiagnostics,Inc., San Leandro, Calif. U.S.A.

Objective: To compare viral and patient characteristics at the time of KS diagnosis,and duration of survival, in early vs recent cohorts of KS patients.

Methods: Sera drawn from 115 patients at the time of KS diagnosis (median date of diagnosis:June 20, 1984) was analyzed for viral and hematologic characteristics. Values were compared for patients diagnosed before July 1984 ("early" KS) and those diagnosed after that date ("late" KS). Duration of survival following KS diagnosis was also compared for the two groups.

Results: Survival averaged 122.9 weeks in the "early" group and 71.9 in the "late." This difference was significant with p=.005. 55 early patients and 52 late patients had laboratory results as follows:

	KS Patient Group:mean (std error)				
	Early		Late		p-value
Beta-2 microglobulin mg/l	5.44	(.38)	4.16	(.24)	.006
Neopterin nmol/l	43.77	(6.74)	27.95	(4.58)	.06
p24 antigen pg/ml	48.78	(11.98)	99.65	(27.96)	.10
Hematocrit	40.25	(.74)	37.70	(1.08)	.06
Sedimentation Rate	31.0	(4.3)	28.1	(2.9)	.58
CD4:CD8 Ratio	0.38	(.03)	0.43	(.08)	.30
T4 helper cells	209.2	(51.8)	149.3	(24.9)	.31

Conclusion: KS survival has notably shortened since the start of the epidemic. While T4 counts, hematocrit, and p24 antigen were more favorable in the early group with longer survival, the abnormal Beta-2, and neopterin levels suggest an immune response to a concomitant infectious process in this group.

W.C.P.39

HUMAN RECOMBINANT IL-2 INDUCES CYTOTOXIC LGL FROM FeLV INFECTED IL-2 IMMUNOSUPPRESSED CATS

TOMPKINS, M., HOLCOMBE H., TOMPKINS, W.
North Carolina State University , Raleigh, NC 27606, USA

Feline leukemia virus (FeLV) causes a broad-spectrum of degenerative or neoplastic diseases in cats characterized by decreased immune competence and acquired immunodeficiency syndrome (AIDS). In other species, including human, retrovirus-induced AIDS is associated with decreased T helper (T_H) and cytotoxic lymphocyte functions. We describe, herein, the morphological and functional characteristics of IL-2-dependent cytotoxic lymphocytes derived from feline peripheral blood lymphocytes (PBL) and the effect of FeLV-induced T_H suppression on the function of these cells. Stimulation of feline PBL with concanavalin A (Con A) followed by culturing in the presence of 50-100 units/ml of Gibbon monkey interleukin 2 (IL-2) or recombinant human IL-2 (rHuIL-2) resulted in marked proliferation and establishment of long-term lymphocyte cultures. Cultured feline lymphocytes possess abundant cytoplasm with large granules similar to the large granular lymphocytes (LGL) in other species. These granules are bound by a bilipid membrane and contain smaller membrane-bound vesicles 50-60 nm in diameter. All feline LGL lines are cytotoxic for feline FL74 lymphoma cells, but none express self-lysis or lysis for other LGL lines, a characteristic of LGL in other species. To determine the effect of FeLV infection on cytotoxicity by PBL and on the establishment of LGL cultures, cats experimentally infected with the immunosuppressive Rickard strain of FeLV were studied. In all cases, PBL from cats with IL-2 immunosuppression failed to yield a primary cytotoxic response, whereas, IL-2 responsive PBL were cytotoxic. In contrast, rHuIL-2 induced cytotoxic LGL from cultured PBL of all FeLV-infected cats, whether or not they were IL-2 suppressed. The results indicate that, like the human HIV-1 infection, the target of FeLV immunopathology is the T_H cell and T_H-dependent cytotoxic functions, the latter of which can be restored by addition of exogenous IL-2.

W.C.P.40

ISOLATION AND PARTIAL CHARACTERISATION OF AN HIV1 RELATED VIRUS OCCURING NATURALLY IN CHIMPANZEES IN GABON

Peeters, Martine*; Cooper, R.W.*; Honoré, C.*; Huet, T.**; Bussi, P.*; Delaporte, E.*.
* Centre International de Recherches Médicales, BP 769, Franceville, Gabon;
** Laboratoire de Biologie Moléculaire, Institut Pasteur, Paris, France

Objective. To better understand the natural history and the evolutionary relationship of the HIV/SIV group of viruses, we tested several chimpanzees from Gabon for HIV antibodies.
Methods. The sera were tested for HIV antibodies with commercial HIV1 tests (ELISA, western blot). Virus was isolated from peripheral blood lymphocytes from the chimpanzee cocultivated with normal (HIV negative) human lymphocytes. Partial characterization was done by electron microscopy, radio-immunoprecipitation and nucleic acid hybridization.
Results. Two cases of wild born chimpanzees, positive for HIV1 antibodies were observed in Gabon. These animals were never experimentally exposed to HIV1 and had no history of inoculation with human blood products. A retrovirus was isolated from one of these chimpanzees and was refered to as SIVcpz. Partial characterization of this virus revealed that it had biological and morphological properties similar to other known human and simian retroviruses, but significant differences could be demonstrated. Several of the viral proteins differ in molecular weight from the known corresponding HIV/SIV proteins. SIVcpz did not induce severe cytopathic effects in human and chimpanzee lymphocytes. Antigenically SIVcpz seems to be closer to HIV1 than to HIV2 and the other SIV's. From nucleic acid hybridation experiments it appears that the virus is different from HIV1, -2.
Conclusion. Chimpanzees can be naturally infected with a novel retrovirus, antigenically close to HIV1.

W.C.P.41

HIV-1 INFECTION IN THE RABBIT

Kindt, Thomas J.*; Kulaga, H.**; Truckenmiller, M.E.*; Recker, D.*; and Folks, T.M.***.
*Lab of Immunogenetics, NIAID, NIH, Bethesda, MD 20892; **NIMH, St. Elizabeth's Hospital, Washington, D. C.; and ***Retrovirus Disease Branch CDC, Atlanta, GA, U.S.A.

Objective. To evaluate the rabbit as a model for HIV-1 infection.
Methods. Outbred New Zealand white rabbits were injected I.V. with human T-cell line A3.01 infected with HIV-1. Serum samples were monitored with a modified ELISA for anti-HIV-1 antibodies and peripheral blood leukocytes were tested for infection by reverse transcriptase activity and PCR after culture in IL-2.
Results. Injection of rabbits with human T-cells infected with HIV-1 has lead to seroconversion within about 4 wks in 19 of 20 rabbits injected and virus can be isolated from peripheral blood cells of infected rabbits after culture in IL-2. The identity of isolated virus as HIV-1 was shown by Southern blot analysis and by presence of predicted restriction enzyme sites in DNA fragments from infected cells after amplification by the PCR technique. Overt effects of HIV-1 infection in rabbits were minimal during the period of observation (9 mo) but pathologic examination upon necropsy revealed enlargement of spleen or thymus in the majority of infected animals and infiltration of lungs with lymphocytes. HIV-1 infection of rabbits previously infected with HTLV-1 caused more evident signs of illness with diarrhea in most animals along with weight loss in some. Several animals showed transient neurologic dysfunction and one had a rapidly progressing breast adenocarcinoma. Current efforts focus on determining the effects of HIV-1 infection on the immune status of the rabbits and in determining whether a homolog of CD4 plays a role in the infection process.
Conclusion. Rabbits can be infected with HIV-1 as shown by seroconversion and isolation of virus from PBL. Effects of the infection on immune function require further definition.

W.C.P.42

p24 ANTIGEN IN THE CSF AND SERUM OF PATIENTS WITH NON-HODGKIN'S LYMPHOMA TREATED WITH STANDARD CHEMOTHERAPY WITH OR WITHOUT GM-CSF

Kahn, James*; Crowe S**; Kaplan L*; Volberding, P*
*University of California San Francisco/San Francisco General Hospital, San Francisco, CA, USA.
**MacFarlane Burnet Centre for Medical Research, Fairfield Hospital, Melbourne, Australia.

Objective. To describe p24 antigen levels from the serum and CSF in patients with non-Hodgkin's lymphoma treated with standard CHOP chemotherapy and randomized to treatment with or without GM-CSF.
Methods. Patients with AIDS-related non-Hodgkin's lymphoma who fulfilled entry criteria for study were treated with standard chemotherapy consisting of cyclophosphamide 750 mg/m^2, vincristine 2 mg, adriamycin 40 mg/m^2 and prednisone 40 mg/m^2 on day 1 of a 21 day treatment protocol. Patients were also treated with methotrexate, 12 mg intrathecally on days 1, 8, 15 and 22. GM-CSF, 10-15 ug/kg was administered subcutaneously days 1-10. CSF and a corresponding serum sample were collected prior to the installation of chemotherapy. Serum and CSF was frozen and assayed using a standard commercial Abbott kit.
Results.

	CSF				Serum			
	Chemotherapy - GM-CSF							
Pt	Day 1	Day 8	Day 15	Day 22	Day 1	Day 8	Day 15	Day 22
1	180	424	441	ND	2928	243	ND	ND
2	0	0	ND	0	2061	24	ND	ND
3	53	0	0	0	156	17	348	286
	Chemotherapy alone							
Pt	Day 1	Day 8	Day 15	Day 22	Day 1	Day 8	Day 15	Day 22
4	0	0	ND	0	0	0	ND	0
5	0	Patient died			ND	ND	ND	ND
6	0	0	0	0	0	0	0	0

Conclusion. Preliminary results indicate that GM-CSF did not have a consistent effect on the p24 antigen from serum or CSF in patients with AIDS associated non-Hodgkin's lymphoma.

W.C.P.43 HIV-1 INFECTION OF HUMAN FETAL CENTRAL NERVOUS SYSTEM TISSUE

Soeiro, Ruy, Tanaka, K., Cihak, W., Udem, S., Rubinstein A., and Lyman, W.D.
Albert Einstein College of Medicine, Bronx, New York U.S.A.

Objective: It is believed that children with congenital HIV-1 infection have been exposed to HIV-1 *in utero*. Because a significant number of these children exhibit neurological manifestation associated with HIV-1 infection, this study was initiated to determine whether HIV-1 DNA could be detected in fetal CNS thereby suggesting a role in pediatric AIDS neuropathology.
Methods: Abortus tissue was collected aseptically from HIV-1 seropositive and control patients at the time of elective pregnancy terminations. Tissues were frozen in liquid N_2 deproteinized by standard phenol extraction. The presence of HIV-1 DNA was determined by molecular hybridization of a "GAG" sequence after amplification (30 cycles) using the polymerase chain reaction. Infected or uninfected H9 cell DNA or sero negative human lymphocyte DNA were included to indicated positive and negative hybridization.
Results: CNS tissue obtained at estimated fetal ages between 13 and 20 weeks showed positive reactions for HIV-1 "GAG" gene DNA in 4 samples from seropositive or risk group women. Other CNS samples from seronegative women failed to show HIV DNA.
Conclusion: Human fetal CNS tissue revealed the presence of HIV-1 DNA suggesting a role of viral infection in early AIDS associated CNS disease. (Supported, in part, by HL 07060, DA 05583, DA 04583, NS 11920, AI 20671, and the Diamond Foundation).

W.C.P.44 NATURAL ANTIBODY PERCEPTION OF AMINO ACID DIVERGENCE WITHIN AN HIV-1 NEUTRALIZATION EPITOPE

Goudsmit, Jaap*, Zwart G.*, Bakker M.*, Epstein L.**, Kuiken C.***, De Wolf F.*.
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, **UMD-New Jersey Medical School, Newark, NJ, USA, ***Dept of Infectious Diseases, Municipal Health Service, Amsteram, the Netherlands.

Objective. Gaining insight into the recognition by natural antibodies of a variable gp120 epitope.
Methods. Nine synthetic peptides were used to screen sera of 134 individuals infected with HIV-1. The oligopeptides were nine amino acids in length and corresponded to the isolate specific "neutralizing" domain in gp120 (V3 region) of HIV-1 strains. LAV-1, RF, SF2, NY5, CDC4, ELI, MAL, Z6 & Z3.
Results. Reactivity to the NY5 peptide was most frequently seen in European sera (67%), reactivity to the LAV-1 peptide in american (53%) and reactivity to the Z3 peptide in african sera (78%). 58% of the sera showed reactivity with more than one of the oligopeptides. Blocking experiments favoured crossreactivity as explanation. A cluster analysis was performed on the (cross-)reactivities of the sera. This analysis grouped together LAV-1, RF and SF2; NY5 and CDC4; Z6, MAL and ELI and Z3 stood alone. This clustering could not completely be explained by comparing physicochemical properties of the oligopeptides. However, the clustering showed the greatest resemblance to a phylogenetic tree of the complete gp120 molecule.
Conclusion. Multiple reactivities are mostly due to cross reaction. The complete envelope may be involved in the selection of B cell clones for the V3 epitope.

W.C.P.45 HIV-1 BRAIN INFECTION: DISTRIBUTION OF INFECTION AND CLINICAL CORRELATES

Cronin, KC; Rosenblum, M; Brew, BJ; Price, Richard W.
Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Objective: To define immunocytochemically: 1. The frequency and topographic distribution of productive HIV-1 brain infection; 2. The histopathological correlates and cell types infected in brain; and 3. The relation of productive infection to the presence and clinical severity of the AIDS dementia complex (ADC).
Methods: Avidin-biotin immunoperoxidase with a monoclonal antibody against a core protein (antibody 25-6, a gift from Genetic Systems, Seattle) was used to map infection in frozen brain sections from 50 HIV-1-infected patients, 37 of whom had been prospectively staged with respect to ADC.
Results: HIV-1 infection was detected 20 brains. The most commonly infected structures included globus pallidus (63% of *positive* brains); corpus callosum (57%); and caudate, putamen, substantia nigra, midbrain, pons and frontal white matter (40-43%). Cerebral cortex was among the least commonly infected (5-11%) and no infection was detected in choroid plexus or dorsal root ganglia. Productive infection was confined exclusively to macrophages, microglia and multinucleated cells derived from these 2 cell types. Infection was detected in 0 of 9 at ADC Stages 0-0.5, 6 of 11 at Stage 1, 1 of 4 at Stage 2, 4 of 6 at Stage 3 and 6 of 7 at Stage 4 and was frequently limited in relation to disease severity.
Conclusion: Productive HIV-1 brain infection correlates with later ADC Stage and is circumscribed both regionally and by cell type. Brain dysfunction is not clearly understood and does not relate to infection in a simple manner.

W.C.P.46 DIFFERENCES IN RISK FOR AIDS AND AIDS MORTALITY IN 49 INDIVIDUALS INFECTED WITH LOW-AND HIGH-VIRULENT HIV VARIANTS.

M. Tersmette, J.M.A. Lange*, R.E.Y. de Goede, J.G. Huisman, J. Goudsmit*, F. Miedema, Central Lab. Netherl. Red Cross Blood Transf. Service and Lab. of Exp. and Clin. Immunology of the Univ. of Amsterdam, *Academic Medical Centre, Amsterdam, The Netherlands.

Fourty-nine seropositive individuals (fourty of whom were asymptomatic at the start of the observation period) were studied longitudinally for the relation between in-vitro properties of their sequential HIV isolates and clinical course before and after the development of AIDS. Per individual 2-8 sequential isolates were studied. Based on the properties of their isolates (Tersmette et al., J.Virol.(1988) 62:2026-2032), the individuals could be divided in three groups. The presence of syncytium-inducing or high-replicating HIV isolates was significant predictive for the development of AIDS within ½-2 years. Azidothymidine (AZT) treatment in the asymptomatic period seemed to delay the onset of AIDS even in the highest risk group. Upon development of AIDS, significant differences in survival between the groups were observed. Also differences in clinical symptoms of AIDS patients from the three groups were observed. These observations stress the importance of the development of virulent HIV variants in the host as a mechanism for AIDS pathogenesis. The existence of a relationship between biological properties of HIV variants and clinical course may provide a possibility to identify asymptomatic HIV seropositive men at high risk for AIDS as a potential target group for early treatment with antiviral drugs.

W.C.P.47 CO-FACTORS IN THE DEVELOPMENT OF KAPOSI'S SARCOMA (KS): HHV-6 INFECTION.

Giraldo, Gaetano*; Beth-Giraldo, E.*; Serwadda, D.**; Katongole-Mbidde, E.**; Romano, F.*; Gallo, R.C.***.
*Ist. Naz. Tumori and University, Naples, Italy, **Mulago Hosp. and Uganda Cancer Inst., Kampala, Uganda, *** Nat. Cancer Inst., Beth., MD, USA.

Objective. To determine the in vivo effect of HHV-6 infection in compromising the immune system and/or its synergistic action in association with other cytopathic or transforming herpes- and retroviruses in Kaposi's sarcoma and various HIV+ and HIV- hospital and healthy populations.
Methods. Identification of antibody prevalence to HHV-6 vs HIV, HTLV-I, CMV, EBV and epidemiologic evaluation in endemic vs epidemic KS (equatorial Africa), classic vs epidemic KS (USA, Europa), in hospital populations and healthy subjects (>1000 sera, Uganda; >1000 sera, USA, Europe).
Results. Prevalence to HHV-6 in Kaposi's sarcoma and matched Blood Donors

KS endemic	(N.54)	Uganda	47yrs	0%	HIV+	67%	HHV-6+	15%	high-titer HHV-6
KS epidemic	(15)	Uganda	35 "	100%	"	55%	"	0%	"
KS classic	(58)	US-Eur	66 "	0%	"	47%	"	0%	"
Blood donors	(50)	US-Eur	60 "	0%	"	43%	"	0%	"
KS epidemic	(18)	US-Eur	34 "	100%	"	44%	"	0%	"
Blood donors	(50)	US-Eur	35 "	0%	"	73%	"	12%	"

Conclusion. a)There is a high prevalence of HHV-6 antibody in KS and healthy subjects; b)HHV-6 seropositive rates decrease with age; c)HIV-1+ patients have <high-titer HHV-6 antibody prevalence then matched HIV-1- controls, probably due to synergistic effect of double infection by HIV and HHV-6.

W.C.P.48 AIDS-KAPOSI'S SARCOMA (KS) DERIVED CELLS EXPRESS CYTOKINES WITH A POTENTIAL ROLE IN THE PATHOGENESIS OF KS LESIONS

Ensoli, Barbara; Nakamura, S.; Salahuddin, S.Z.; Wong-Staal, F.; Gallo, R.C.
Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD, U.S.A.

KS is a proliferative disease of unknown etiopathogenesis and frequent manifestation of AIDS. Cell cultures established from KS lesions of AIDS patients (AIDS-KS cells) are able to promote their own proliferation (autocrine) and proliferation of normal endothelial cells, fibroblasts and cells of hematopoietic lineage (paracrine). Furthermore, the AIDS-KS cells induce neoangiogenesis, and a KS-like lesion in nude mice. Studies at the molecular level indicated that the AIDS-KS cells express mRNA specific for basic and acidic fibroblast growth factor (bFGF, aFGF), interleukin-1 α and β (IL-1α and -1β), granulocyte-monocyte colony stimulating factor (GM-CSF), transforming growth factor β (TGFβ) and platelet derived growth factor β (PDGF-β). Particularly bFGF and IL-1β are expressed at high levels, released into culture media, and responsible for inducing AIDS-KS and normal endothelial cell proliferation. The results suggest that *in vivo* KS cell proliferation with cytokines production could be the final step leading to the appearance of the composite KS lesion.

W.C.P.49

MISCELLANEOUS CARCINOMAS DEVELOPING IN PATIENT'S WITH HIV INFECTION.

Parick Mark: Sharma D, Gill PS, Bernstein L, Bernstein-Singer M, and Levine AM. University of Southern California, Los Angeles, CA, USA.

Objective: To describe the occurrence of solid cancers excluding Kaposi's sarcoma in patients with various stages of HIV infection.
Methods: The pathologic tumor types of all solid tumors excluding Kaposi's sarcoma were examined in males ages 20 to 50 years of age diagnosed at the Los Angeles County/USC Medical Center from 1986 through 1988. Patients were then assessed for the presence of HIV infection by either serologic evidence or specific indicator diseases. For each patient identified with HIV infection and solid tumor, stage of HIV infection, extent of cancer, treatment modality and survival data were obtained.
Results: From a total of 359 males diagnosed with solid cancers 27 (7.5%) had co-existent HIV infection. 12 patients (pts) had Stage II disease, 7 pts Stage III and 8 pts Stage IV. Tumor types included Gastrointestinal 9 (33%), Germinal cell 4 (15%), Primary Lung 4 (15%), Basal Cell Carcinoma of skin 3 (11%), unknown primary 2 (7%) and 1 each (4%) of disseminated malignant melanoma, carcinoma-sarcoma of prostate, malignant schwanoma, squamous cell carcinoma of nose, and astrocytoma.
Conclusion: 1) Uncommon solid carcinomas are being diagnosed in pts with HIV infection; 2) Survival is often shortened because of the underlying immune dysfunction due to HIV; 3) More study is needed to establish the role of HIV in the development of these solid tumors.

W.C.P.50

49 UNUSUAL HIV-RELATED MALIGNANT TUMORS.

Tirelli Umberto, Vaccher E., Sinicco A., SabbataniS., Giudici M. G., Zagni R., Monfardini S. et al. Gruppo Italiano Cooperativo AIDS-Tumori (GICAT). ITALY

Objective. To evaluate the characteristics of unusual HIV-related tumors observed in Italy.
Results. Since 1986 the GICAT has collected 49 HIV-related tumors other than KS and NHL predominantly among intravenous drug abusers (IVDA), in accordance with the overall epidemiology of AIDS.

Neoplasia	N°	Risk Group	Clinical and Pathological Features
Testis ca.	13	9 IVDA	7 carcinoma, 5 seminoma.
Cervix ca.	9	9 IVDA	median age 24, 8/9 ca. in situ
Lung ca.	8	6 IVDA	median age 34, 5 NSCLC
Acute leukemia	5	3 IVDA	4L$_3$ (Burkitt-like), 1 M$_2$
Multiple myeloma	2	2 IVDA	age 29 and 39, 1 with KS
Colon ca.	2	1 IVDA	age 25 and 55, rapid course

Only 1 case was reported of glioblastoma, thyroid ca., thymoma, melanoma, renal ca. pancreatic ca., CLL,CML, oral ca. (male polytransfused) and anal ca. (female prostitute with anal intercourse). Testis ca. occurred in patients (pts) mainly in early HIV infection without adversely affecting full dose chemotherapy or radiotherapy. Cervix ca. in 8/9 pts treated with conisation would suggest PAP test screening in young IVDA. Lung ca. occurred in a young age group with rapid progression and death within 2 mo. Intensive chemotherapy in Burkitt-like ALL was not adversely affected by HIV infection and 2 CR were achieved (11 and 15 mo. duration).
Conclusion. In this IVDA-based series, while oral and anorectal tumors did not occur, there is a wide spectrum of unusual HIV-related tumors which is probably underestimated because not diagnostic of AIDS. The required therapeutic approach may not be consistently influenced by HIV infection, as for KS and NHL.

W.C.P.51

HIV-HPV INFECTION AND PENILE CARCINOMAS (PC) IN UGANDA

Buonaguro, Franco M.*; Beth-Giraldo, E.*; Tornesello, M.L.*; Katongole-Mbidde, E.**; Monaco, M.* and Giraldo, G.*.
*Natl. Cancer Inst., Naples, Italy, ** Makerere University, Kampala, Uganda.

Objective. To determine effects of HIV epidemic on the incidence and the evolution of PC in Uganda, by a possible modulation of HPV infection.
Methods. DNA extracted from PC biopsies and cell lines, of HIV negative and positive patients, are tested for the presence of HPV strains by dot blot and Southern blot analysis.
Results. HIV seropositive patients have been reported to present a significantly high prevalence of cervical dysplasia (C. Bradbeer, Lancet 1987; M. Byrne et al., Lancet 1988) and signs of HPV infection (P. Crocchiolo et al., Lancet 1988). We are determining HPV incidence in biopsies from ugandan patients with PC before and during the HIV epidemic. Furthermore, two permanent cell cultures, from penile carcinomas of Ugandan patients, have been established. Some of the markers typical of oncotypes of neuroectodermal origin have been identified. HPV 6, 11 e 16 DNA sequences have not been detected. A weak hybridization signal is present with a HPV 18 DNA probe in reactions performed at high stringency (Tm-20). A stronger hybridization signal is obtained at low stringency (Tm-50), suggesting the presence of an HPV strain with low homology to HPV 18.
Conclusions. We are going to a) determine the incidence of HPV in PC in Uganda, b) verify the HIV role on HPV incidence and PC evolution, and c) to isolate and characterize the eventual new HPV strain.

W.C.P.52

KAPOSI'S SARCOMA-LIKE CELL LINES FROM SIMIAN AIDS WITH SUBCUTANEOUS AND RETROPERITONEAL FIBROMATOSIS ASSOCIATED WITH TYPE D RETROVIRUS (SRV-2) INFECTION

Tsai,Cheng*;Tsai,C.**;Sligh, J.*;Woon,M.*;Roodman, S.*
St. Louis University, St. Louis, Missouri, USA, **Washington Regional Primate Research Center, Seattle, Washington, USA.

Objective. To establish KS-like cell lines from SAIDS associated with SRV-2.
Methods. Two KS-like lesions, subcutaneous and retroperitoneal fibromatosis from macaques with SAIDS associated with SRV-2 infection were cultured in regular RPMI or DMEM media supplemented initially with brain derived growth factor(BDGF). Immunocytochemical, cytologic, ultrastructural and viral studies were carried out on various passages of culture (over16) during a 12 months period.
Results. Both cell lines propagate vigorously in 10% FCS media without BDGF after 4th passage and can grow with only 0.5% FCS unlike the control monkey fibroblast. Cytology and immunochemistry of both cells are similar and demonstrated heterogeneous populations of endothelial(±60%), pericytic/smooth muscle(±15%), and primitive mesenchymal/fibroblastic differentiations. Arborizing multinuclear syncytial giant cells are prominent in early culture. Both cell lines are diploid (DI=1.02) with high prolifertive activity (S=25% G2/M=30%) but show no growth in soft agar. Evidence of autocrine/paracrine growth is further suggested by the presence of cytoplasmic phosphotyrosine and BDGF-like proteins in these cultured cells.
Conclusion. Two KS-like cell lines from simian AIDS associated with SRV-2 were established for future basic and clinical study.

W.C.P.53

CERVICAL NEOPLASIA IN HIV-INFECTED WOMEN

Friedmann, Wolfgang*; Schäfer, A.*; Schwartländer, B.**
* Dept. of Obstetric and Gynecology, Freie Universität Berlin, FRG; **AIDS-Center, Bundesgesundheitsamt, Berlin, FRG

Objective:

To evaluate the meaning of cervical neoplasia and Papillomavirus-infection (HPV) in HIV-Infected women.

Methods:

We investigated cytological smears and cervical tissue from 108 HIV-infected women for dysplastic alteration and HPV-infection.

Results (Selection):

Dysplastic alterations were seen 15 times more often in HIV-infected women than in women without HIV-infection. Histologically 10 CIN's and 5 invasive carcinoma of cervix were detected. Nearly half of the smears without dysplastic alteration and more than 60% of smears with dysplastic alteration showed signs of HPV-infection. There was a strong correlation of clinical status of HIV-infection and dysplastic alteration and cancer.

Discussion:

On the basis of a high prevalence of HPV a routine-screening for cervical dysplastic alteration is essential in HIV-infected (immunosuppressed) women.

CHARACTERISTICS OF IN VITRO CULTURE OF KS-DERIVED CELLS,

Peter Biberfeld*, Shuji Nakamura**, Zaki S. Salahuddin**, Barbara Ensoli**, Robert C. Gallo**, *Department of Pathology, Karolinska Institute, Stockholm, Sweden, **Lab. of Tumor Cell Biology, N.C.I., N.I.H., Bethesda, MD, USA.

Culture medium (CM) from retrovirus infected T-cell lines prompte the continuous, in vitro growth of cells from biopsies of Kaposi's sarcoma (1).
These cells have endothelial like features and produce in vitro several growth factors notably bFGF-like activity (2). These cells elicit a strong angiogenic reaction in nude mice and on chicken allantoic membranes. Studies are in progress on the identity of the CM with growth promoting activity to KS-derived cells and the possible expression of autocrine and paracrine activities by these in vitro cultured cells.

W.C.P.55 VACUOLAR MYELOPATHY: HIV-1 EXPRESSION CORRELATES WITH EXTENT OF CLINICAL AND PATHOLOGIC DISEASE.

Barbara Weiser, N Peress, D Eilbott, D LaNeve, R Seidman, H Burger, SUNY, Stony Brook, NY, USA.

Spinal cord (SC) disease and a distinct vacuolar myelopathy (VM) characterized by vacuolation and macrophage infiltration of SC white matter both occur following HIV-1 infection. We have shown previously in 3 SC from AIDS patients with severe myelopathy that HIV-1 RNA was expressed in the 3 SC and localized to macrophages in vacuolated areas of white matter. To determine if (1) HIV-1 RNA is present in the SC of AIDS patients with a range of cord pathology and (2) HIV-1 expression is correlated with clinical and pathologic disease, we studied 17 SC from AIDS patients and 9 controls. In situ hybridization was used to detect HIV-1 RNA, and immunohistochemistry, to identify cell type. Immunohistochemical staining of the 10 cords with VM showed macrophage infiltration of vacuolated regions of SC white matter, with the degree of infiltration parallel to the degree of clinical myelopathy. Cords from AIDS patients with SC lymphoma and toxoplasmosis showed focal macrophage infiltration, and 6 cords from controls without SC disease showed rare, if any, macrophages. Of the 17 cords obtained from AIDS patients at autopsy, HIV-1 RNA was detected in 6 of 10 with vacuolar myelopathy, 0 of 5 without SC pathology, and 0 of 2 with focal macrophage infiltration secondary to other SC disease (toxo and lymphoma). Three control cords obtained from patients with other SC disease showed no HIV-1 RNA. In the 10 AIDS cords with VM, the amount of HIV-1 RNA expression correlated with the extent of both SC pathology and clinical disease. These data support a direct role for HIV-1 in the pathogenesis of AIDS myelopathy.

W.C.P.56 HIV-1 ANTIGENIC VARIANTS WITH DISTINCT BIOLOGICAL PROPERTIES EMERGE AT THE DECLINE OF THE HOMOLOGOUS ANTIBODY

De Jong, Jean-Jacques*, Tersmette M.**, Krone W.*, Meloen R.**, Miedema F.**, Goudsmit J.*.
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, the Netherlands

Objective. To study the antigenic variability of the V3 region (aa 296-331) of the external envelope of 120 kDa (gp120) of HIV-1 in natural infection.
Methods. Sequential isolates of two patients progressing to AIDS and showing a transition from non-syncytium to syncytium forming capacity were used to study antigenic variability in the V3 domain of gp120. The V3 coding domain was amplified using the polymerase chain reaction (PCR). Direct sequences of the V3 coding domain were determined and confirmed by cloning and sequencing. Antibody recognition of sequential sera of these individuals was determined for peptides covering the complete V3 domain of the isolates.
Results. The transition from non-syncytium to syncytium inducing isolates was marked by clustered nucleic acid changes of which three were consistent. This resulted in one amino acid change crucial to antibody binding. Decline of the antibody to the syncytium forming antigenic variants preceded the emergence of these variants.
Conclusion. Antigenic variants appear to be selected by antibody to the V3 domain of gp120 during natural infection.

W.C.P.57 EARLY APPEARANCE OF CROSSREACTIVE ANTIBODIES SPECIFIC FOR A COMMON EPITOPE IN GP41 and HLA CLASS II ANTIGENS CAN INTERFERE WITH NORMAL IMMUNE FUNCTIONS IN AIDS PATIENTS.

Hana Golding*; Shearer, G.M.**; Hillman, K.*; Manischewitz, J.*; Golding, B.*
*DV and DBBP, CBER, FDA, **NCI, NIH, Bethesda, MD, U.S.A.

Amino acid sequence comparison between HIV-1 envelope and human HLA class II antigens identified a highly homologous sequence in the C-terminus of gp41 and the N-terminus of all class II beta chains. Screening of sera from HIV-1 infected individuals, reveals a high frequency (35-40%) of antibodies specific for the common epitope in both early and late stages of the disease. These sera as well as murine mAb against this sequence reacts also with class II-bearing (uninfected) cells (B, T, Macrophages).
Objective. To study if the crossreactive Ab (CRAb) can interfere with T cell immune functions and contribute to elimination of class II^{+} cells.
Methods. Patients' and controls' sera were added to normal T cells stimulated with tetanus toxoid or allogeneic stimulators. Sera were tested in Ab-Dependent Cellular Cytoxicity (ADCC) of class II^{+} cell lines. CRAb were purified by affinity chromatography (peptide-sepharose-column).
Results. Sera containing CRAb were found to be potent inhibitors of the proliferative responses of normal CD4^{+} T cells. The same sera could also kill class II-bearing (uninfected) cell lines. Both reactivities could be adsorbed by peptide linked-sepharose beads. The purified CRAb were all IgG. In many cases such CRAb were present in sera from asymptomatic patients who still had CD4^{+} T cells ($>500/mm^{3}$), but demonstrated in vitro unresponsiveness to various recall antigens (influenza, tetanus toxoid, etc.).
Conclusions. HIV-1 infection may lead to generation of CR autoantibodies capable of impairing immune functions early during the course of disease.

W.C.P.58 HIV-INFECTED HUMANS, BUT NOT CHIMPANZEES, HAVE CYTOTOXIC T LYMPHOCYTES THAT LYSE UNINFECTED CD4^{+} CELLS

Patricia Moran*; Ledbetter, J.*; Sias, J.*; Fultz, P.**; Eichberg, J.***; and Zarling, J.*. *Oncogen, Seattle, Washington, USA; **Yerkes Primate Research Center, Emory University, Atlanta, Georgia, USA; ***Southwest Foundation for Biomedical Research, San Antonio, Texas, USA.

Objective. It has been suggested that autoimmunity contributes to the depletion of CD4^{+} T cells in HIV-1 infected humans, based on findings that some HIV-1-infected humans have autoantibodies reactive with antigens on uninfected CD4^{+} cells. We asked whether HIV-1-infected humans also have CTL lytic for uninfected CD4^{+} cells that may contribute to the depletion of CD4^{+} cells.
Methods. Fresh PBL from humans and chimpanzees were tested for their ability to lyse ^{51}Cr labelled uninfected CD4^{+} cells and other cells.
Results. HIV-1-infected homosexuals, but not uninfected homosexuals or heterosexuals, have PBL that lyse uninfected CD4^{+} T cells from humans and chimps but not human B lymphoblastoid cells or mouse T cells. The cytotoxic PBL were concluded to be CTL that are CD3^{+},CD8^{+},CD4^{-}, CD16^{-},TCR-1-αβ^{+}, based on findings that lysis of uninfected CD4^{+} cells was diminished by (1) mAb to CD3, which inhibits CTL but not NK activity; (2) treatment of PBL with a mAb to CD8, but not to CD16 and C; (3) mAb WT31 to TCR-1-αβ which is expressed on MHC-restricted CTL; and (4) mAb to HLA class I framework determinant. In contrast, PBL from HIV-1-infected chimpanzees, which do not develop AIDS, lacked detectable CTL lytic for uninfected CD4^{+} cells.
Conclusion. Circulating CTL, lytic for uninfected CD4^{+} cells, that we detected in blood from HIV-1-infected humans but not from chimpanzees, may contribute to HIV-1-induced immunopathology in man.

W.C.P.59 INDUCTION OF HUMAN IMMUNODEFICIENCY VIRUS FROM CHRONICALLY INFECTED CLONES BY CYTOKINES AND PHARMACOLOGICAL AGENTS REQUIRES PROTEIN KINASE C ACTIVATION.

Kinter, Audrey, Maury, W., Poli, G., Fauci, A.S., Folks, T.M. NIAID, NIH, Bethesda, MD. U.S.A.

Objective. This study was designed to define second messenger pathways by which cytokines and pharmacological agents induce HIV expression from chronically infected cells.
Methods. The U1 (promonocytic) and ACH-2 (lymphocytic) chronically HIV infected clones express low to undetectable constitutive levels of HIV. Virus replication in these cells can be increased 2-20 fold by phorbol esters (PMA), recombinant cytokines [rTNFα,rGM-CSF (U1 only)], and cytokine enriched cell supernatants. We have tested inhibitors (isoquinolinesulfonamide derivatives) and activators of protein kinases (PK) as well as agents which modify calcium activity, for their effect on baseline and cytokine induced virus expression in the U1 and ACH-2 clones. Virus expression was measured as supernatant reverse transcriptase activity, by western blot and nuclear run-on analysis.
Results. H7, the most potent inhibitor of PKC activity, effectively blocked (75%-90%) HIV induction by all cytokines and pharmacological agents in both the U1 and ACH-2 clones. Those inhibitors, H8 and HA1004, which are more selective for cyclic nucleotide dependent kinases, did not suppress viral induction. Specific activation of PKC, by synthetic diacylglycerol and bryostatin, resulted in a 2-8 fold increase in viral replication in both clones. Activators of cyclic nucleotide kinases were not effective in inducing virus. Agents which increase intracellular levels of calcium can potently synergize with PKC mediated induction in U1 but not ACH-2 cells.
Conclusion. Upregulation of HIV by cytokines and pharmacological agents requires the activation of PKC. Evidence exists of a calcium related, but ultimately PKC dependent, event which can also upregulate virus expression.

W.C.P.60 MORPHOLOGICAL CHANGES OF THE VACUOLAR MYELOPATHY IN AIDS

Artigas, Juan; Niedobitek , F; Grosse, G; Bonk, G. and Heise W.*

Department of Pathology and * Department of Medicine;
Auguste-Viktoria-Krankenhaus, Rubensstraße 125; 1000 Berlin 41
FEDERAL REPUBLIQUE OF GERMANY

Objective. To describe the morphological changes of the vacuolar myelopathy (VM). Such morphological studies are rare and thus the pathogenesis of this frequent condition is poor understood.
Methods. The spinal cord of 42 HIV-infected patients was examined with conventional histology, immunhistochemistry and electron microscopy.
Results. In 24 cases a mild (7 cases), moderate (12 cases) or severe myelopathy (5 cases) was found. Fusiform vacuoles, 50 to 180 µm in diameter and 200 to 800 µm in lenght, delimited by a thin sheat of distended myelin, are present in the white matter. Clusters of macrophages, phagocytising axons of apparently preserved structure, are found into the vacuoles. The foamy macrophages contain rest of axons; only in one case with severe tissue disruption they contain myelin debris too. In 5 cases, some macrophages, microglia cells and multinucleated cells show HIV-antigen (p24 and gp41). A strong astrogliosis is present in the white and grey matter. Proliferation of microglia cells is present between the neurons in the grey matter.
Conclusions. VM is a more frequent condition as previously thought. In VM a process of phagocytosis directed against the axon cylinders occurs simultaneously with vacuolar degeneration of the white matter. The vacuoles arises between the axolemma and the myelin sheat.

W.C.P.61 HIV-1 INFECTION OF HUMAN FETAL CENTRAL NERVOUS SYSTEM ORGANOTYPIC CULTURES.

Lyman, William, Tricoche, M.; Kress, Y.; Hatch, W.; Chiu, F.-C. and Soeiro, R. Albert Einstein Coll. Med., Bronx, NY. USA.

Objective. Most cases of pediatric AIDS are likely congenital and the product of fetal infection by HIV-1 *in utero*. Because a significant number of children with AIDS exhibit neurologic disease, this study was initiated to determine if HIV-1 can infect fetal central nervous system (CNS) cells and characterize the resultant pathology.
Methods. Explants of human fetal cerebra were established and maintained in organotypic culture for up to 8 weeks. Initial studies, using light and electron microscopy (LM and EM) in combination with immunocytochemistry and Western blot technology, confirmed that the cultures contained normal nervous tissue cellular elements. Test cultures were exposed to either infectious or heat-inactivated HIV-1 isolates. Infection of tissue was determined by immunocytochemistry, molecular hybridization, and an infectious centers assay. Pathology was assessed by LM and EM.
Results. Cultures exposed to infectious HIV-1 (IIIB strain) for up to seven days showed an array of morphologic changes. HIV-1 infection of the cultures was confirmed *in vitro* tests and virus-like particles were observed in CNS tissue culture cells.
Conclusion. Organotypic cultures of human fetal CNS tissue may provide a valuable experimental model to define the targets and mechanisms associated with the neuropathology of AIDS.
(Supported, in part, by DA 05583, DA 04583, NS 11920, NS 25873, AI 20671, and the Diamond Foundation).

W.C.P.62 USE OF POLYMERASE CHAIN REACTION (PCR) TO DETECT THE PRESENCE OF HIV-1 DNA IN SUBPOPULATIONS OF PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMCS) IN INFECTED INDIVIDUALS

Schnittman, Steven*; Psallidopoulos, M.C.**; Lane, H.C.*; Baseler, M.***; Salzman, N.P.** and Fauci, A.S.*. *NIAID, National Institutes of Health, Bethesda, MD, USA, **Georgetown University, Washington, DC USA, ***PRI, Frederick, MD, USA.

Objective. We have previously demonstrated that within PBMCs, HIV is expressed in vivo in AIDS patients predominantly in the T cell subpopulation which, in contrast to in vitro infection, continues to express CD4. Our prior studies utilized methods which detect HIV in cells actively producing virus. The present study determines which subsets of PBMCs harbor HIV DNA (both latent and active) and what is the precursor frequency of these virus-infected cells.
Methods. Highly purified (>98-99%) subpopulations of PBMCs were obtained from HIV infected individuals by fluorescent activated cell sorting. PCR was then performed on the DNA from these cells to detect specific HIV-1 DNA.
Results. Cells were sorted for CD4 (T helper), CD8 (T suppressor), CD14 (monocyte), and CD19 (B cell) populations. HIV-1 specific DNA was detected in the purified CD4+ T cell population in all 15 patients examined by PCR. HIV-1 DNA was not present in the CD8 or CD19 cell subsets, and rarely in the peripheral monocyte fraction. PCR performed on serial dilutions of the sorted CD4+ T cells revealed that > 1/100 cells are infected in AIDS patients, a viral burden much greater than previously reported.
Conclusions. The CD4+ T cell is the reservoir for HIV in the peripheral blood of infected individuals, and greater than 1% of these cells may contain virus in vivo in patients with AIDS. This high level of infection may be the primary cause for the progressive decline in CD4+ T cell function and number in AIDS patients.

W.C.P.63 HIV-INFECTION ALTERS THE INTERACTION OF MACROPHAGES WITH *TOXOPLASMA* AND *LEISHMANIA*.

Kalter, D. C., Gendelman, H., Orenstein, J*, Meltzer, M. S.**, and Reed, S***.
H. M. Jackson Fndn.,*George Washington Univ.,**Walter Reed Army Inst. Res., Washington DC, ***Seattle Biomedical Res Inst., Seattle WA, USA.

Objective. Examine ability of HIV-infected macrophages to ingest and kill intracellular parasites.
Methods. Monocytes from normal donors were cultured in medium with colony stimulating factor-1 (MCSF, Cetus Corp, Emeryville CA). Monocytes were infected at 7 days with a monocytotropic HIV-1 strain, ADA. Ten days after virus infection, *T. gondii* or *L. mexicana* promastigotes were added to HIV-infected and control monocytes. Cultures were examined 4 and 20 hrs after addition of parasites: percent monocytes infected with parasites and number of parasites/infected cell were quantified by microscopic analysis.
Results. At 4 hrs, 40% of control and 10% of HIV-infected monocytes were free of parasites. The number of parasites/monocyte in HIV-infected cultures was significantly greater than that in control cultures at both 4 and 20 hrs. Electron microscopy revealed virus particles and parasites within the same monocyte.
Conclusions. Monocytes infected with HIV *in vitro* ingest parasites, but show altered infectivity and microbicidal activity. These observations may explain the pathogenesis of opportunistic infection in tropical areas.

W.C.P.64 INFECTION OF HUMAN FETAL BRAIN MACROPHAGES AND MIXED NEURAL CELLS IN TISSUE CULTURE BY HIV-1.

Humazaki, Kai*,**; Goldman, H.*; Bai, X-Q**; Vong, I.*; and Wainberg, M.A.*,**
*McGill University-Montreal Children's Hospital Research Institute, Montreal, Quebec, Canada; **Sir Mortimer B. Davis - Jewish General Hospital, Montreal, Quebec, Canada.

Objective. To clarify the role of brain macrophages and other neural cells in the pathogenesis of neurological disorders associated with AIDS.
Methods. Cultures of macrophages and mixed neural cells were established from human fetal brains of legally-induced aborted fetuses and infected with the HTLV-III$_B$ strain of HIV-1.
Results. Expression of HIV-gag gene products (p17 and p24) was detected by immunofluorescence after 6 days and peaked at 10 days after inoculation of both the macrophage and mixed neural cell cultures. Positive results were also obtained when the culture fluids of both the macrophage and mixed neural cell cultures were assessed by both antigen capture (p24) and reverse transcriptase (RT) assays. In addition, cellular disarrangement and the appearance of multinucleated giant cells was observed. Cultures of mixed neural cells derived from the substantia nigra and infected with HIV-1 revealed both giant cell formation and massive reduction of cell numbers.
Conclusion. These results indicate that brain macrophages and other neural cells are susceptible to primary infection by HIV-1. These systems afford good opportunities for investigations of the neurological consequences of HIV-1 infection and for anti-viral drug studies in neurological tissue.

W.C.P.65 GENERAL DECREASE OF LEUKOCYTE VIABILITY OF AIDS PATIENTS IN SERUM-FREE MEDIUM

Guetard, Denise* ; Favier, V.* ; Hardefelt, M.* ; Adams, M.* and Montagnier, L.* .
* Viral Oncology Unit, Institut Pasteur, Paris, France.

Objective. To study the mechanism of AIDS pathogenesis and to design an *in vitro* test for the follow up of antiviral drugs.
Methods. PBMC of HIV seronegative, HIV seropositive and patients with ARC or AIDS were separated from heparinized blood on a sepracell gradient. After washing, cells were incubated in a serum-free medium specially designed for lymphoid cells. Cell viability was evaluated daily by blue-trypan exclusion.
Results. While PBMC of uninfected individuals show very little loss of cell viability after 3 days of culture, cells from AIDS patients display a rapid decay varying from 10 to 40% of dead cells after 3 days. HIV positive and ARC patients show intermediate values. Cell death was often preceeded by production of cytoplasmic debris and membrane bullous formation. Fractionation of PBMC in subpopulations indicate that T8 as well as T4 lymphocytes and non T cells are decaying at about the same rate under these culture conditions.
Conclusion. An increased cell fragility, amplified by the serum-free conditions, may be an important parameter in AIDS pathogenesis. Results of antiviral treatment on such a parameter will be described.

W.C.P.66 MECHANISMS OF HIV-INFECTIONS IN MACROPHAGES

Zorr, Bernd; Kaunath, Th. and Habermehl, K.-O.
Institute for Clinical and Experimental Virology, Free University of Berlin, Hindenburgdamm 27, 1000 Berlin 45, FRG.

Blocking experiments with receptor-specific monoclonal antibodies (OKT4a) lead to the conclusion that the T4 molecule is an essential receptor-component for monocytes/macrophages. Neutralization tests with T4-positive MT4 cells and peripheral blood monocytes which process the T4 molecule and Fc-receptors (FcR) were performed in order to investigate if antibody-virus-complexes are infectious for monocytes/macrophages. Using a HIV (wild type) and a respective type-specific antiserum it can be demonstrated that antibody-virus-complexes which are not infectious for MT4 cells are still able to infect monocytes/macrophages. Moreover, in certain ranges of antibody concentration, an enhancement of infectivity can be observed. Human non-immune sera did not show this effect. Simultaneous application of a monoclonal antibody against OKT4a together with the antibody-virus-complex leads to a complete protection of the monocytes/macrophages. This indicates that antibody-virus-complexes are able to enhance the infectivity for monocytes/macrophages in vitro. The specific interaction of the HIV with the T4 molecule, however, is an essential prerequisite for the initiation of the cycle of virus-reproduction. The results indicate that the enhancement of infectivity is caused by an interaction between the Fc-receptor of the macrophage and the antibody of the complex. The high affinity of the T4-gp120 binding on the one hand and the genetic variability of the env-region on the other are essentials for the effectivity of the interaction with the T4-receptor.
This mechanism gives an explanation for the fact that at present immunisation with vaccines against infections with lentiviruses seems to be rather harmful than beneficial.

W.C.P.67 CNS AND LYMPH NODE CHANGES IN HIV INFECTION.

Peter Biberfeld*, Carlo Parravicini**, Anna-Lena Petrén*, Marianne Ekman*, Anna Forwit*, R.C. Gallo***, *Immunopathology Lab., Department of Pathology, Karolinska Institute, Stockholm, Sweden, **Cattedra di Anatomia Patologica, Università di Milano, Ospedale "L. Sacco", Milano, Italy, ***Lab. of Tumor Cell Biology, N.C.I., N.I.H., Bethesda.

HIV-induced lesions in brains and lymph nodes of infected individuals were studied by immunohistochemistry and in situ hybridization. Micronodular lesions in the brains were mainly composed of microglial cells, monocyte/macrophages and lymphoid cells, predominantly CD8+.

Gag and env. coded antigens as well as virus RNA were associated with glial cells and monocyte/macrophages. The glial cells and monocyte/macrophages expressed antigens defined by the Mab's KiM6 and 9.4 and to variable degree CD4. In lymphadenopathic nodes only gag antigens were demonstrable and exclusively in germinal centers, mostly associated with dendritic follicular cells (DFC). Rare cells showed evidence of HIV replication also predominantly located to the germinal centers. Follicular involution was associated with destruction of DFC and follicular infiltration of CD8+ cells. Both in CNS and lymph nodes, antigen presenting cells constitute the main source (reservoir) of virus replication. A possible cytotoxic role of CD8+ cells to HIV-infected cells is suggested.

W.C.P.68 CYTOMEGALOVIRUS (CMV) INDUCTION OF TUMOR NECROSIS FACTOR (TNF) SECRETION BY HUMAN MONOCYTES/MACROPHAGES MAY CONTRIBUTE TO TISSUE INFLAMMATION IN AIDS PATIENTS.

Smith, Phillip D., Lamerson, C.L., Saini, S.S., Wahl, L.M. and Wahl, S.M.
NIDR, National Institutes of Health, Bethesda, MD.U.S.A.

Objective. To determine whether CMV induces monocyte and tissue macrophage expression of TNF.

Methods. CMV isolated by standard techniques from an AIDS patient with CMV colitis was inoculated into cultures of purified human monocytes. Infection was confirmed by immunoperoxidase staining with monoclonal antibody to the 68 kD immediate early (IE) antigen. TNF secretion was measured by bioassay and TNF gene expression was analyzed by Northern blot. TNF expression by mucosal macrophages obtained from AIDS patients and normals was monitored by in situ hybridization.

Results. Monocytes inoculated with the clinical isolate, but not mock-infected cells, expressed CMV IE antigen. Although neither CMV-infected nor control monocytes spontaneously secreted TNF, infected monocytes produced several-fold greater amounts of TNF in response to a second stimulus. In parallel, CMV-infected monocytes expressed enhanced levels of TNF mRNA. In addition, TNF-specific RNA was detected in mucosal macrophages in biopsy specimens from 2 AIDS patients with CMV colitis, but not in specimens from healthy subjects or AIDS patients without CMV colitis.

Conclusions. TNF is expressed in increased amounts in CMV-infected monocytes in vitro and in mucosal cells during CMV enteritis. TNF secretion by tissue macrophages may contribute to the inflammatory changes that occur in various organs in patients with AIDS and CMV disease.

W.C.P.69 ALTERED BRAIN METABOLITES IN AIDS DEMENTIA AS MEASURED BY MAGNETIC RESONANCE SPECTROSCOPY

Jensen, Peter C., Hubesch, B., Parks, R., Deicken, R., Krell, P., Weiner, M. W., et al.
Department of Medicine, Veterans Administration Medical Center and The University of California, San Francisco, California, USA

Eight controls and 17 HIV seropositive patients with clinical evidence of the AIDS Dementia Complex (ADC) were evaluated with neurologic, psychiatric, and neuropsychological testing. Patients with focal brain lesions were excluded. All subjects were scored on the basis of cognitive, behavioral and neurologic function utilizing a standardized form. Subjects were studied with Magnetic Resonance Imaging and Spectroscopy (MRI/MRS). Brain concentrations of adenosine triphosphate (ATP), phosphocreatine (PCr), inorganic phosphate (Pi) and other phosphate-containing metabolites, such as phosphomonoesters, were assessed by MRS. Preliminary results suggest that patients with moderate to severe ADC have lower brain ATP/Pi ratios than do normal subjects. There was no correlation between ATP/Pi or PCr/Pi ratios and clinical stage of HIV infection, nor with the degree of cerebral atrophy and ventricular enlargement as measured by MRI. Cerebral atrophy, when present, was positively correlated with lower dementia scores. These preliminary findings suggest that brain energy metabolism, as measured by phosphate metabolites, may be reduced in patients with ADC. This altered metabolism may be independent of the presence of cerebral atrophy. Further studies to validate these early findings are in progress.

W.C.P.70 INDUCTION OF HIV-1 FROM A LATENTLY INFECTED CNS-DERIVED CELL LINE

Mark A. Laughlin, Janet M.Harouse, F.Gonzalez-Scarano
University of Pennsylvania Medical Center, Philadelphia, PA, U.S.A.

Objective: HIV-1 causes a persistent, latent and non cytopathic infection of MED 217 cells (a medulloblastoma derived cell line). We further defined the nature of this infection in terms of level of baseline viral gene expression and methods of induction of viral transcription, p24 production and production of infectious virions.

Methods: MED 217 were exposed to HIV-1_{3B} and a modified infectious center assay performed to rescue virus. The cellular RNA was extracted and probed for viral specific nucleic acid and in addition the supernatant assayed for tne production of p24 and infectious virions. A number of manipulations (such as treatment with phorbol esters, growth factors and UV light) were then performed in an attempt to induce viral replication. Results: Although in general infection in these CD4 negative cells was inefficient, with increasing time of exposure to virus approximately 1:10 cells became infected. Under baseline conditions no viral specific RNA, supernatant p24 or infectious virions could be demonstrated. Treatment with phorbol myristate acetate results in the production of viral specific RNA, p24 (≈20 fold increase over baseline sensitivity) and infectious virions. Treatment with UV light similarly results in the production of p24, but the time course is markedly different, indicating different mechanism for the activation of viral replication by these methods. Treatment with cloned growth factors is being perfomed. Conclusions: By increasing the time of exposure to virus, infection of MED 217 cells can be made efficient, allowing the dissection of mechanisms of induction of viral replication. Initial results indicate that accepted mechanisms of activation of the HIV-1 promoter will induce viral replication.

W.C.P.71 IN VIVO ACTIVATION OF ALVEOLAR MACROPHAGES AND LYMPHOCYTES IN SPONTANEOUS INTERSTITIAL LUNG DISEASE DUE TO THE VISNA-MAEDI VIRUS IN SHEEP

Cordier, Geneviève*; Cadoré, J.L.**; Cozon, G*. and Mornex J.F.***.
*INSERM U80, CNRS URA 1177, UCB, Hopital E. Herriot, Lyon, France ; **Laboratoire associé de Recherches sur la pathologie des Petits Ruminants, INRA-Ecole Vétérinaire, Lyon, France.***Laboratoire d'Immunologie et de Biologie Pulmonaire, Hopital Louis Pradel ; Lyon, France

Objectives. Chronic and/or degenerative disorders involving the joints, the nervous system and the lungs are a common feature of lentivirus infection in humans and animals. Sheep infected by the retrovirus visna/maedi develop a chronic interstitial lung disease characterized by an alveolitis including macrophages, neutrophils and lymphocytes. Lung parenchymal damage associates [illegible] and interstitial fibrosis which might be related to the activation of accumulating alveolar cells. In order to investigate the respective role of lymphocytes and macrophages in the pathogenesis of the disease we performed phenotypical and functional characterization of the alveolar cells.

Methods. Bronchoalveolar lavage were obtained from healthy (n=19) and maedi (n=17) animals. Diagnosis was made by pathology and evidence of a macrophage lentiviral infection. Monoclonal antibodies and indirect immunofluorescence analysed by flow cytometry were used to assess the expression of cell membrane antigens. The release of a neutrophil chemotactic factor was quantified in a micro-chemotaxis assay; fibronectin was dosed in ELISA.

Results. In maedi when compared to healthy animals, a significant decrease of the $CD4^+$ lymphocytes was observed (20%±3.7 vs 42±3.4; p<0.05) without significant changes in $CD8^+$ lymphocytes (31%±7.3 vs 26±3.4; ns). Activated lymphocytes expressing MHC class II antigens were present in both subpopulations. Both the total number of alveolar macrophages (1.8±0.5 10^6/ml vs 0.9±0.1) and the percentage of MHC Class II-positive macrophages (50.4%±4.5 vs 15.5±4.0) were significantly higher (p<0.05). In keeping with the neutrophilic alveolitis, the spontaneous release of a neutrophil chemotactic factor was increased in maedi (30.3±21.5 U/ million macrophages x 3h vs 13.2±14.7, p<0.05). Further evidence of alveolar macrophage activation was brought, in maedi, by an increased spontaneous release of fibronectin (31.0±8.7U/10^6 cells vs 9.2±2.8, p<0.01).

Conclusion. Although restricted to macrophages infection by visna-maedi induces activation of both lymphocytes and macrophages in the alveola. Macrophages release excess amounts of mediators able to play a role in the pathogenesis of the disease. In addition, through increased expression of Ia-like antigen they might potentiate the lymphocyte response.

W.C.P.72 MORBIDITÉ SYSTÉMIQUE ET EXPRESSION RÉTROVIRALE (infection productive) CHEZ LE PORTEUR HIV.

Leibowitch, Jacques*; Mathez, D.*; Cesari, D.*; Bélilovsky, C.*/**;
Gerin, I.**; Deleuze, J.** et Paul, D.***.
*Hopital Raymond-Poincaré/Université René-Descartes, Garches/Paris-ouest, France; **Hopital Tarnier, Paris, France; ***Abbott Laboratories, North Chicago, Etats-Unis.

Objectifs: relations entre statut clinique et immunologique, progressivité éventuelle et infection rétrovirale productive in vivo.

Méthodes: évaluations du statut clinique (CDC), lymphocytes T4/µl, antigénémie p24/25 (S-p24) ; le niveau d'infection rétrovirale productive in vivo est quantifié ex-vivo à partir des cellules mononucléées du sang à division/maturation bloquée (60000 rads, CMN RAD). La vitesse moyenne de propagation (score % du maximum) du matériel HIV aux lymphoblastes in vitro est fonction pour un spécimen donné du nombre de cellules contenant du HIV préformé in vivo (abstract connexe). Les mêmes systèmes de co-culture et quantifications sont appliqués aux CMN non-irradiées.

Résultats:

SCORE CMN RAD (% du maximum)	CLINIQUE (a)	T4/µl ±sd	S-p24 +/n
00-20	II-III(8)	752±222	2/8
21-40	II-III(5),IV (3)	580±320	5/8
41-60	II-III(3),IV(5)	560±455	4/8
61-90	II-III(1),IV(10)	231±263	9/11

		PROGRESSEURS							NON PROGRESSEURS

Conclusions: la progression de la maladie HIV systémique (clinique, lymphopénique) est associée à une expression HIV active in vivo, mesurable ex vivo.

W.C.P.73 ALTERED IgG-SUBCLASS DISTRIBUTION IN LYMPH NODE CELLS AND SERUM OF PATIENTS WITH HIV INFECTION

Müller, Fredrik*; Frøland, S.S.** and Brandtzaeg, P.*
*Lab.for Immunohistochemistry and Immunopathology and **Medical Department A, University of Oslo, The National Hospital, Rikshospitalet, Oslo, Norway.

Objective. To study the distribution of plasma cells producing IgG subclasses in lymphoid tissue of patients with HIV infection and compare this with IgG subclass levels in serum.
Methods. Lymph node specimens from 15 patients with persistent generalized lymphadenopathy (HIV+) and 11 patients with lymphadenopathy of other causes (controls), were processed for paired immunofluorescence. Sections were stained with subclass-specific antibodies and an anti-IgG antibody. The proportion of cells containing each subclass was then calculated. IgG subclasses in serum was measured by ELISA (Nycomed A/S, Oslo, Norway) in 14 of the patients with HIV infection and 12 blood donors. Results are given as medians and 25-75 percentiles.
Results. The fraction of lymph node cells producing IgG1 was 84% (81%-88%) in HIV+s versus 76% (67%-83%) in the controls ($p<0.05$). For IgG2, the fraction was 3% (2%-8%) in HIV+s versus 8% (3%-15%) ($p<0.05$). No differences were observed for IgG3 or IgG4. In serum, total IgG was 17.6 g/l (15.1-20.8 g/l) in HIV+s and 11.9 g/l (10.6-13.4 g/l) in the blood donors ($p<0.005$). IgG1 was elevated in HIV+s: 8.9 g/l (7.5-9.6 g/l) versus 5.4 g/l (5.1-6.5 g/l) ($p<0.005$). Conversely, IgG2 was reduced in HIV+s: 1.5 g/l (1.3-3 g/l) versus 3.6 g/l (3-4.2 g/l) ($p<0.05$)
Conclusion. In lymph nodes from patients with HIV infection, the proportion of cells producing IgG1 is increased whereas that producing IgG2 is reduced. This shift is in accordance with the IgG subclasses seen in serum.

W.C.P.74 THE EFFECT OF HIV ON MEMBRANE LIPIDS OF LYMPHOCYTES

A. Klein*, P. Gordon*, S. Ramcharitar*, L. Marcure**, A. Malkin* and M. Wainberg**
*Clinical Biochemistry Dept., Sunnybrook Medical Centre, University of Toronto, Toronto, Ontario. Canada, **Lady Davis Institute, Jewish General Hospital, McGill University, Montreal, Quebec, Canada.

High content of unsaturated fatty acids (FAS) in membrane lipids lead to an increase in cell membrane fluidity and can explain cell fusion and death through the loss of membrane integrity. In the present work after H-9 and MT-4 lymphocyte cell lines were infected with HIV, a quantitative and qualitative analysis of their FAS were made. These cell lines were chosen because MT-4 is killed after HIV infection and H-9 is not. Infected and non-infected cells were extracted with methanol:chloroform solutions. The lipids were transmethylated to produce FA methyl esters and analyzed by gas chromatography. HIV infection was characterized by: 1) a significant rise (180-250%)($p<0.05$) in the desaturation of essential FAS-represented by linolenic (18:3) and arachidonic (20:4) acids-in both cell lines, 2) a significant elevation ($p<0.05$) in the concentration of the saturated FA stearate (18:0) (180%) and palmitate (16:0) (187%) only in the MT-4 cell line, and 3) a significant rise ($p<0.05$) in the desaturation of stearate to oleate (18:0 to 18:1) (171%) only in the MT-4 cell line. The results demonstrate that infection by HIV is characterized by elevated desaturation of essential FAS, whereas, killing of cells shows increase in both formation of non-essential FAS and desaturation of stearate. The mechanism by which these changes take place is not at all clear.

W.C.P.75 SIMIAN IMMUNODEFICIENCY VIRUS INHIBITS BONE MARROW HEMATOPOIETIC PROGENITOR CELL GROWTH.

Watanabe, Mamoru; Ringler, D.J.; DeLong, P.A. and Letvin, N.L. Harvard Medical School, New England Regional Primate Research Center, Southborough, Massachusetts, USA.

Objective. To explore pathogenic mechanisms of depressed hematopoietic function in AIDS.
Methods. Granulocyte/macrophage (CFU-GM) and erythrocyte (BFU-E) progenitor cell colonies were assessed in two layer agar and methylcellulose culture systems, respectively. SIV_{mac} isolations from bone marrow were assessed in adherent cell cultures in the absence of lectin or cytokines.
Results. Both bone marrow CFU-GM and BFU-E were decreased in number in many SIV_{mac}-infected rhesus monkeys. SIV_{mac} was readily isolated from bone marrow cells of infected monkeys and was shown to be harbored in macrophages rather than T lymphocytes. The *in vitro* infection of normal bone marrow cells by SIV_{mac} inhibited colony formation. A striking *in vivo* correlation between increased SIV_{mac} load in bone marrow cells and decreased hematopoietic progenitor cell colony growth was also shown. Finally, inhibition of SIV_{mac} replication in bone marrow macrophages by anti-CD4 antibody resulted in increased progenitor cell colony growth from those bone marrow cells.
Conclusion. The infection of bone marrow macrophages by the AIDS virus leads directly to depressed bone marrow hematopoietic progenitor cell growth. Moreover, inhibition of AIDS virus replication in these macrophages should induce significant improvement in hematopoietic function.

W.C.P.76 INFECTION OF GLIAL CELLS EXPRESSING THE CD4 MOLECULE

Janet M. Harouse, Mark A. Laughlin, Jeffrey Hastings, Harvey Friedmann, Brian Godfrey, F.Gonzalez-Scarano
Departments of Neurology, Microbiology and Medicine, School of Medicine, University of Pennsylvania, PA USA 19104-6076

Objective: The U373 glioblastoma-derived cell line can be infected with HIV-1 (several strains) to cause a persistent, latent and non-cytopathic infection. A number of measures, including treatment with phorbol esters (PMA) will induce viral replication. To determine whether CD4, which is normally not present in these cells, could affect replication we prepared stable transfectants containing the human CD4 molecule.
Methods: We prepared stable transfectants of glioblastoma line U373 with a plasmid expressing the human CD4 molecule under the control of the Moloney murine sarcoma virus LTR by co-transfecting with a plasmid expressing the hygromycin resistance gene. The stable transfectants were further selected with anti-CD4 antibody by panning and by antibody dependent cell cytoxicity. Results: A variable level of expression of CD4 was seen in the initial transfectants but all of the epitopes tested, including the carboxy and amino regions of the molecule were represented. We cloned the high expressing cells and used several different strains of HIV-1 and HIV-2 in infections. We monitored viral replication by antigen capture for p24 and by the production of infectious virus and compared these with two other cell populations: (1) clones of U373 glial cells uniformly infected with $HIV\text{-}1_{3B}$ (2) randomly infected U373 cells. After infection with $HIV\text{-}1_{3B}$ there was an initial round of low-level replication ([p24] = 100 pg/ml) followed by a persistent latent infection. Conclusions: These results indicate that other factors besides the entry pathway are responsible for the characteristics of HIV-1 infection of glial cells and allow us to begin to dissect the diverse elements that determine tropism.

W.C.P.77 ROLE OF ENDOTOXIN IN MODULATION OF HIV EXPRESSION IN A MONOCYTIC CELL LINE

Molina,Jean-michel*;Chhay,H.*;Amirault,C.*; Dinarello,C.** and Groopman,J.*.
*Harvard University,Boston,Massachusetts,USA,
**Tufts University,Boston,Massachusetts,USA.

Objective. To determine the role and mechanism of action of endotoxin (LPS) in modulating HIV expression in monocytic cells.
Methods. THP-1 cells, chronically infected with HIV-1/IIIB, were stimulated for 24 hours with LPS (0.5-10 µg/ml), recombinant TNFα (rTNFα), recombinant IL-1β (IL-1β) (0.1 to 10 ng/ml) and polyclonal antibodies against TNFα and IL-1β. TNFα and IL-1β were measured in supernatants using RIA. Viral expression was assessed by the level of reverse transcriptase activity (RT) in the supernatants.
Results. LPS stimulation of THP-1 cells resulted in a dose-dependent increase of RT (20 to 100% over unstimulated cells $p<0.01$), and in significant production of TNFα (1 ng/ml) and IL-1β(0.1ng/ml). Antibodies against TNFα, but not against IL-1β were able to block 50% of the increase in RT after stimulation with 10 µg/ml of LPS ($p<0.05$). Furthermore, rTNFα but not rIL-1β increased RT in a dose dependent manner($p<0.01$).
Conclusion. LPS stimulation of HIV-infected monocytic cells can significantly increase virus production and this effect may be due in part, to the release of TNFα by LPS stimulated cells.

W.C.P.78 PRODUCTION DE TNFα ET D'IL-1β PAR LES CELLULES DE LA LIGNEE MONOCYTAIRE INFECTEES PAR LE VIH

Molina,Jean-michel*;Scadden,D.*;Ferriani,R.*; Byrn,R.*;Dinarello,C.** and Groopman,J.*.
*Université de Harvard,Boston,Massachusetts,Etats-Unis,
**Université de Tufts,Boston,Massachusetts,Etats-Unis.

Objectif.Mesurer la production de TNFα et d'IL-1β par les cellules de la lignée monocytaire infectées par le VIH.
Méthodes.TNFα et IL-1β ont été mesuré par RIA et l'ARNm par Northern Blots.La lignée THP-1 infectée par VIH-1/IIIB a été stimulée par 5µg/ml d'endotoxine (LPS).Les macrophages ont été infectés par VIH-1/IIIB,VIH-1/BaL et VIH-2.
Résultats.Les cellules THP-1 et les macrophages infectés par differentes souches de VIH ne produisent pas spontanément de quantité détectable de TNFα, d'IL-1β ou d'ARNm . Après stimulation par LPS des cellules THP-1,TNFα,IL-1β et de l'ARNm sont produits,sans difference significative entre cellules non infectées ou infectées de façon chronique.En revanche,les cellules THP-1 en phase aigüe d'infection,plus differenciées, produisent après stimulation,des quantités de cytokines 2 à 13 fois plus élevées que les cellules non infectées ou infectées de façon chronique ($p<0.01$).
Conclusion.Les cellules de la lignée monocytaire infectées par le VIH ne produisent pas spontanément de TNFα ou d'IL-1β mais peuvent en réponse à un stimuli comme LPS produire des quantités importantes de ces deux cytokines.

W.C.P.79 HIV-2 ENVELOPE GLYCOPROTEINS AND CELL FUSION.

Mulligan, Mark J., Kumar,P., Hui,H., Ritter,D., Hahn,B., Compans,R.
University of Alabama at Birmingham, Birmingham, Alabama USA

Objective: To utilize recombinant vaccinia viruses (rVV) to study the expression and function of env genes of HIV-2/ROD, the HIV-2 prototype which is fully pathogenic *in vitro*, and HIV-2/ST, a recent isolate with less virulent *in vitro* behavior, .
Significance: The envelope gene products of HIV-1 and -2 are essential to virus attachment, entry, and pathogenicity, as well as cell fusion and host immune responses. Most data indicate virus entry into CD4+ target cells occurs via viral-cell membrane fusion at neutral pH. The infected cells can produce syncytia with uninfected CD4+ cells at neutral pH. A virus unable to produce cell fusion despite normal infectivity may have an altered molecular mechanism of cell entry and membrane fusion. We hypothesize such a change in HIV-2/ST. Unlike other HIVs, this virus does not induce cell fusion or cell death; infected cells exhibit fully productive infection (mRNA production, RT activity), but the rate of free virus entry into cells is retarded.
Methods: HIV-2/ST had been isolated from a healthy West African prostitute; HIV-2/ROD was provided by L. Montagnier. The env genes were inserted into rVVs and evaluated for production of envelope glycoproteins using metabolic labelling and RIP/PAGE. Function of recombinant env gene products was assessed by infection of CD4+ cells and quantitating cell fusion. Hyperimmune rabbit antisera was produced using recombinant envelope glycoproteins.
Results: Recombinant HIV-2/ROD env gene product gp160 is produced and recognized by antisera. Infection of CD4+ cells indicates the products are cleaved and transported to the cell surface in functional form where they mediate cell fusion. rVV-ST has been constructed.
Conclusions. Recombinant VV carrying HIV-2 env genes synthesize, process, and transport functional recombinant envelope glycoproteins. The env gene product of HIV-2/ROD causes infected cells to fuse with uninfected CD4+ cells. These methods will be useful to determine whether the cell fusion defect of HIV-2/ST is a function of its env gene.

W.C.P.80 CMV IS NOT A COFACTOR IN THE PROGRESSION OF HIV INFECTION.

Brodie, HL*; Byrne WR*; Drew, W.Lawrence**; Graham C***; Kadekis A*; and Williams MT*. *Letterman Army Medical Center, Presidio of San Francisco, California, USA, **Mount Zion Hospital and Medical, San Francisco, California, USA, ***Sociometrics, Inc., Hyattsville, Maryland, USA.

Objective.To determine if coinfection with CMV affects the decline of CD_4 cells in HIV infected patients.
Methods.We have compared to rate of decline of CD_4 cells in HIV seroconverting military personnel who are CMV seropositive versus those who are CMV seronegative. Regression analysis was used to calculate the daily decline in CD_4 counts following HIV seroconversion. Blood samples were obtained at 6 months intervals to permit calculation of the rate of CD_4 cell decline.
Results.The mean initial CD_4 counts were 519 in the CMV seropositives and 457 in the seronegatives (NSS;p0.51). Fifty CMV seropositives showed a slope of CD_4 decline/day of - .3101 versus - .2044 in 7 CMV seronegatives. This difference is not statistically significant (P=0.71) when the rates are compared using students T test.
Conclusion.We conclude that CMV is not a necessary cofactor in the pathogenesis of HIV infection.

W.C.P.81 ABERRANT CIRCADIAN PHYSIOLOGIC, IMMUNE AND ENDOCRINE RHYTHMS IN HIV-INFECTED INDIVIDUALS.

Rhame, Frank*; Sothern, R.B.*, Sackett-Lundeen, L.**; Suarez, C.* Hrushesky, W.J.M.*; and Haus, E.**
*University of Minnesota, Minneapolis, **St.Paul-Ramsey Medical Center, St. Paul, Minnesota, USA.

Objective: To assess circadian variation of parameters relevant to the pathophysiology and laboratory monitoring of HIV infection.
Methods: For 24h in a clinical research setting, 8 HIV-infected persons (3 AIDS, 3 ARC and 2 asymptomatic; all free of acute illness) underwent 4-h assessments of oral temperature lymphocyte subsets (CD3, CD4, CD8, B1), monocytes, neutrophils; HIV antigen, neopterin (n=6), beta-2-microglobulin; plasma cortisol, aldosterone, beta endorphin; and serum zidovudine and urinary excretion (n=3). Two patients underwent detailed zidovudine pharmacokinetics at midnight and noon. Healthy, age-matched adults served as controls.
Results: A significant circadian rhythm in oral temperature was found in 6 of the 8 patients, with unusual early morning peaks in 2 patients. Usual lymphocyte rhythmicity peaking between 6 P.M. and midnight, including all studied subsets, was lost. The normal circadian rhythm in neutrophil and monocyte concentrations was absent in patients with low counts. Rhythmicity in HIV antigen and neopterin could be demonstrated for some patients, but not as a group phenomenon since the daily peaks and valleys differed from patient to patient. HIV-infected subjects had elevated beta-2 microglobulin and rhythmicity, which was not seen in controls. Circadian variation similar to controls in beta-endorphin, aldosterone and cortisol concentrations was seen. Following constant dosing, substantial within-day variation in serum and urine zidovudine levels was seen, but half-lives at midnight and noon were similar.
Conclusion: The normal marked lymphocyte rhythmicity is ablated in HIV-infected persons, even if asymptomatic, and cannot be explained by loss of cortisol rhythmicity.

W.C.P.82 REGULATION OF CYTOKINE RECEPTOR EXPRESSION BY HIV

Lau, Allan S; Dion M; and Livesey J F.
Division of Infectious Diseases, Hosp for Sick Children, Toronto, Canada.

Interferons (IFN) have been shown to interact synergistically with tumor necrosis factor (TNF) in cytotoxic and antiviral activities. Both cytokines are capable of suppressing the replication of HIV in vitro. To elicit biological activities, these cytokines bind to specific high affinity cell surface receptors. We have previously demonstrated down regulation of IFN-α receptors on blood lymphocytes from AIDS patients and consequent hyporesponsiveness of the cells to IFN in vitro. We postulate that HIV gene products are capable of down regulating the expression of cytokine receptors. The expression of IFN-α receptors on CD4+ cells (specifically CEM, HUT, and Jurkat) was studied using IFNα2 (Schering) labeled with ^{125}I to high specificity by a lactoperoxidase method. Saturation binding curves were generated with the ^{125}I-IFNα2 and the binding characteristics were analyzed to obtain the receptor numbers. CD4+ cells were infected with HIV in vitro and the levels of p24 antigen and reverse transcriptase activities were determined to monitor the replication of HIV. We have demonstrated a progressive down regulation of IFN-α receptors during the progress of HIV infections in vitro. To evaluate the effects of HIV on the induction of IFN regulated enzymes, HIV infected HUT cells were treated with IFN-α2 and assayed for 2-5A synthetase activities. We have shown diminution in 2-5A synthetase induction in infected cells, compared to controls. Similarly, we have demonstrated down regulation of TNF-α receptors in CD4+ cells by measuring the binding of ^{125}I-TNF-α (Genentech) during the course of HIV infection. We are currently investigating the role of individual viral genes in the regulation of cytokine receptors. Thus, these studies indicate that HIV is capable of suppressing the expression of IFN-α and TNF-α receptors. This may be one of the mechanisms by which HIV evades the antiviral actions of IFN and TNF in vivo.

W.C.P.83 ENHANCED PRODUCTION OF TUMOR NECROSIS FACTOR IN SYMPTOMATIC HIV INFECTIONS.

Lau, Allan S; Read SE; Der S.
Division of Infectious Diseases, Hosp for Sick Children, Toronto, Canada.

Tumor necrosis factors (TNF) are polypeptides produced by macrophages and monocytes in response to inflammation and sepsis. They are also potent mediators of cachexia and autoimmune processes. We have previously demonstrated upregulation of TNF receptors and induction of TNF synthesis by the acid-labile IFN-α present in AIDS sera. We were interested to determine whether synthesis of TNF is enhanced during the progress of HIV infections in patients. Blood mononuclear cells (PBM) were obtained from normal controls and patients with asymptomatic HIV infection (CDC classification group II), persistent lymphadenopathy (III), constitutional disease (IVa), and opportunistic infections (IVc). TNF production by the cells was measured by a cytotoxicity assay on L929 cells using Hu-TNF-α (Genentech) as a standard. One unit of TNF is defined as the concentration of the cell culture supernatant which produces cytopathic effects on 50% of the L cells. PBM from normal controls produced low levels of TNF (1.1±0.96 U/ml, n=14). The levels of TNF production by the cells from Group II, III, IVa, and IVc patients were 2.2±2.0 (n=9), 7.8±7.9 (n=12,$p<.05$), 6.4±7.2 (n=5,$p<.05$), and 18.7±14.7 (n=13,$p<.01$) U/ml respectively. The cytotoxic activities in the supernatants can be completely neutralized by anti-TNF-α antibodies. Moreover, the cells from symptomatic patients (group III and IV) were hypersensitive to endotoxin resulting in further induction of TNF synthesis, compared to normal controls and asymptomatic patients. Thus these results indicate that the synthesis of TNF is enhanced during the progress of HIV infections and the cells from the symptomatic patients are hypersensitive to TNF inducers. This may be one of the mechanisms involved in the pathophysiology of cachexia and sepsis in symptomatic AIDS patients.

W.C.P.84 ANALYSIS OF BRAIN FROM AIDS PATIENTS FOR HIV-1 DNA SEQUENCES USING THE POLYMERASE CHAIN REACTION (PCR)

Gadler, Hakan*; Hahn, BH**; Shaw, GM**; Brew BJ*; Rosenblum M*; Price, RW* *Memorial Sloan-Kettering Cancer Center, New York, NY, and **University of Alabama at Birmingham, Birmingham, AL, USA

Objective: To determine whether HIV-1 proviral DNA can be detected by PCR in the brains of patients with mild AIDS dementia complex (ADC). While it is clear that HIV-1 infection can be demonstrated by a variety of techniques in the brains of AIDS patients, such demonstration is confined almost exclusively to those with more advanced symptomatology and pathology. The presence and role of HIV-1 in milder ADC has not yet been established.
Methods: DNA was extracted from 56 frozen brain samples obtained at autopsy from 27 HIV-1-infected individuals and assessed using a primer pair from the HIV-1 *env* gene flanking the immunodominant region. Dilution experiments, using cloned HIV sequences from which the primer pairs were derived, indicated a sensitivity of 8.2 fg DNA by visual inspection of the gel and 66 ag when probed by Southern blotting using a reacting sequence.
Results: In samples from brains known to be HIV-1 "positive" by immunohistochemistry or Southern blot, HIV-1 DNA was amplified. However, in most "negative" brains, PCR was also negative and in those with circumscribed infection by immunohistochemistry, PCR was likewise limited.
Conclusion: These initial results suggest that viral sequences in brains of patients with milder ADC are below the level of PCR detection using this single primer pair. Further studies using additional primer pairs and well-characterized tissue specimens are needed to determine if early ADC relates to active HIV-1 replication, restricted gene expression or indirect factors.

W.C.P.85

EFFECTS OF TUMOR NECROSIS FACTOR (TNF-a), GAMMA INTERFERON AND GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM-CSF) ON HIV REPLICATION IN HIV-INFECTED HUMAN MYELOMONOCYTIC CELL LINES

Cortes, Eduardo**; Koeffler, HP*; Zhao, JQ*; Mitsuyasu, RT*. *University of California, Los Angeles, USA; **Faculdade de Medicina UFRJ, Rio de Janeiro, Brazil.

Objective. To study the effects of TNF-a, gamma interferon, and GM-CSF on HIV antigen expression in chronically infected human myelomonocytic leukemic cell lines.
Methods. HTLV-IIIB infected ML-3 (myelomonoblastic), THP-1 (monoblastic), and U-937 (monocytic) cells at a concentration of 3 x 10^5 cells/ml were incubated with cytokine at 3 log concentrations for 24-102 hours. Cell viability was assessed by trypan blue exclusion and HIV replication by HIV p24 antigen capture on cell free supernatants of cultured viable cells.
Results. TNA-a had a marked cytolytic effect on HIV infected and uninfected cells at concentrations of 10^2-10^4 u/ml. No HIV inhibitory effects were seen with any of the cytokines alone or in combination. HIV p24 was significantly increased in ML-3 cells by TNF-a and by GM-CSF and in U-937 cells by GM-CSF alone.
Conclusion. The effect of these cytokines on HIV expression in chronically infected cells appears to be cell specific and may represent differences in viral regulation in cells at different stages of maturation.

W.C.P.86

PRESENCE OF HIV-1 IN THE SPERMS OF HIV-SEROPOSITIVE INDIVIDUALS BY DNA-HYBRIDIZATION AND IMMUNOGOLD METHODS

Bagasra, Omar**; Freund, M.*; Condoluci, D.***; Heins, B.*; Weidman, J.** and Comida J.*** Departments of Microbiology*, Obstetrics and Gynecology** and Medicine*** University of Medicine and Dentistry of New Jersey, Camden, New Jersey, USA.

Objective. To explore the role of sperm in the transmission of HIV-1.
Methods. Semen specimens were collected at weekly intervals from three patients who were seropositive for HIV-1. Semen specimens were washed and pellets were examined for presence of HIV by electron microscopy, by use of HIV-specific monoclonal antibodies and immunogold labelling and by HIV-specific DNA probes and *in situ* hybridization.
Results. Electron microscopic analysis of sperm showed HIV-1 like particles in the sperm of all 9 specimens. Further evaluation with HIV specific DNA probes and immunogold labelled monoclonal antibodies confirmed the presence of HIV-1 in the sperm of HIV seropositive individuals but their absence in HIV-seronegative individuals.
Conclusion. Presence of HIV-1 in the sperms of HIV-seropositive individuals indicates a potential mechanism for the venereal transmission of HIV by sperm from HIV seropositive individuals to their sexual partners.

W.C.P.87

PRESENCE OF TUMOR NECROSIS FACTOR IN THE CEREBRAL SPINAL FLUID (CSF) OF AIDS PATIENTS WITH HIV ENCEPHALOPATHY

Perez, Victor L.*; Janssen, R.*; Spira, T.*; Fauci, A.S.**; DuBois, R.***; Folks, T.*, *Centers For Disease Control, Atlanta, GA, USA; **National Institutes of Health, Bethesda, MD, USA; ***Atlanta Medical Associates, Atlanta, GA USA.

Objective. To assess the presence of Tumor Necrosis Factor-alpha (TNF) in the CSF of HIV seropositive patients with HIV encephalopathy (HIVE).
Methods. CSF from 3 patients with HIVE, 6 AIDS patients without central nervous system (CNS) disease, 5 patients with HTLV-I associated myelopathy/tropical spastic parasis (HAM/TSP), and 1 HIV seronegative control individual, was tested for the presence of the TNF using the Wehi 164-clone 13 bioassay. Positive samples were confirmed by neutralization with a rabbit antibody to human TNF-alpha.
Results. TNF was detected in significantly more patients with HIVE (3/3) than AIDS patients without CNS disease (1/6, p=.05). There was a trend toward significance comparing presence of TNF in patients with HIVE (3/3) to HAM/TSP patients (1/5, p=.07, Fisher's Exact Test, 1-tailed). No TNF was detected in the HIV seronegative control individual.
Conclusion. The current data suggest that detectable TNF levels are present in the CSF of patients with HIVE but to a much lesser degree in HIV+ patients with no neurological manifestations or in patients with HTLV-I associated neurologic disease.

W.C.P.88

DETECTION OF UNINTEGRATED VIRAL DNA IN HIV-1 INFECTION: USE OF A RAPID AND EASY PCR METHOD

Jurriaans, Suzanne*, Geelen J.*, Epstein L.**, Clement M.*, Lange J.*, Goudsmit J.*.
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, **UMD-New Jersey Medical School, Newark, NJ, USA.

Objective. To study the kinetics of unintegrated viral DNA (UVD) in HIV-1 infected cells *in vitro* and presence of UVD *in vivo* in HIV-1 infected children and in homosexual men.
Methods. UVD was detected by use of the polymerase chain reaction (PCR) in which the long terminal repeat (LTR) in covalently closed circular viral DNA was amplified. The specificity of the amplified sequences was confirmed by Southern blot analysis using an LTR-specific probe and sequencing the primed fragment.
Results. Closed circular viral DNA was detected within one day post-infection in HTLV-IIIB infected Molt-3 cells. Depending on the infecting virus titer, UVD was undetectable for a short period early in infection, but persisted thereafter.
Brain and spleen tissues of HIV-1 infected children with HIV-1 associated progressive encephalopathy were analyzed for the presence of UVD. In both tissues high levels of UVD were detected, indicating active infection at both sites. In blood of AIDS-patients UVD could also be detected.
Conclusion. UVD can be detected in HIV-1 infected cells both *in vivo* and *in vitro* by use of the PCR and it may be used as a marker for active infection and disease progression.

W.C.P.89

SERUM CAPACITY TO INHIBIT REVERSE TRANCRIPTASE IN VITRO DISTINGUISHES HIV-1 INFECTION FROM HIV-2 OR SIV INFECTION

Wolfs T.*, Goudsmit, Jaap*, Geelen J.*, Schellekens H.**, Barin F.***
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, ** Primate Center TNO, Rijswijk, the Netherlands, ***Laboratoire de Virologie, LHRU Bretonneau, Tours, France.

Objective. To study the inhibition of HIV-1 and SIV reverse transcriptase by human and rhesus macaque serum positive for HIV-1 or HIV-2/SIV antibodies.
Methods. Inhibition of HIV-1 or SIV reverse transcriptase activity was assayed after incubation with HIV-1 or HIV-2/SIV antibody positive serum.
Results. The domain to which reverse transcriptase inhibiting antibodies were elicited appeared to be highly antigenic. Sixty-seven percent (48/72) of individuals had HIV-1 reverse transcriptase inhibiting (RTI) antibodies one year after seroconversion for HIV-1, 90% (9/10) of HIV-2 antibody positive persons had SIV-RTI antibodies and all four experimentally SIV-infected rhesus macaques developed SIV-RTI antibodies. Low cross-reactivity between HIV-1 and HIV-2/SIV-RTI antibodies was observed. Of 10 HIV-1-RTI sera 2 reduced SIV-RT activity by more than 50% (mean reduction 85% versus 24%). Only 1 of 9 SIV-RTI human sera reduced HIV-1-RT (mean reduction 74% versus 25%). This serum however showed a shared reactivity against both HIV-1 and HIV-2 envelope proteins.
Conclusion. These results indicate that the HIV-1 domain inducing RTI antibodies is antigenically different from the HIV-2/SIV domain.

W.C.P.90

EXPRESSION OF A POTENTIAL HIV RECEPTOR ON HUMAN GASTROINTESTINAL EPITHELIAL CELLS (GIECs)

Moyer, Mary Pat; Huot, R.; Wideman, D., and Martin, D.
The University of Texas Health Science Center at San Antonio, TX, USA.

Objective. To determine if human GIECs express a CD4-related receptor which might allow HIV attachment.
Methods. Immunoassays of tissue sections and early passage cultures of GIECs from human normal GI (small intestine and colon) or human colon cancer (HCC) sources were done using Leu3a and OKT4 monoclonal antibodies. In addition to an immunoreactive subpopulation of lamina propria lymphocytes in tissue sections, staining was observed at the microviller surface, or glycocalyx, in a subset (2 to 25%) of GIECs in sections or in cell cultures derived from different individuals. Reactivity of well characterized GIECs maintained for 10 or more subcultures, and protein immunoblot detection of 80kd and 106kd proteins verified that carryover of CD4+ lymphoid cells did not explain the immunoreactivity. Furthermore, the established HCC lines tested in these experiments were not immunoreactive.
Conclusion. These observations suggest that GIECs bear CD4-related epitopes, which are associated with the cell surface or mucinous glycolyx. Since such surface molecules could serve as sites for HIV attachment and subsequent viral infection, these data are relevant to virus transmission, gastroenteropathies associated with AIDS or ARC, and the possibility that GIECs may serve as a reservoir for HIV. Support was provided by PHS grant R01 DK40825 and The UTHSCSA Center for Human Cell Biotechnology.

W.C.P.91 CELL-SPECIFIC CONTROL OF HIV PRODUCTION IN CHRONICALLY INFECTED GLIAL CELLS

Mellert, W.*, Fesl, H.*, Kleinschmidt**, A.*, Müller-Lantzsch, N.***, Erfle, Volker*

*GSF-Abteilung für Molekulare Zellpathologie, D-8042 Neuherberg, **Medizinische Poliklinik der Universität München, D-8000 München, ***Institut für Medizinische Mikrobiologie und Hygiene, D-6500 Homburg, West-Germany.

Objective. Evaluation of HIV regulation in potential virus reservoir cells in the brain (glial cells).
Methods. Establishment of chronically infected glioma cell lines. Measurement of HIV proteins, RNA expression, and production of infectious virus.
Results. We established chronically HIV-1 infected glioma cell lines harbouring an integrated HIV genome. The cell lines express structural proteins, which can be detected in the cytoplasm but they release extremely low amounts of infectious virus in comparison to other infected cell types (T-cells, monocytes/macrophages, mesenchymal cells). Furthermore, high amounts of intracellular nef protein with a molecular weight of 27 kD is produced in these cells.
Conclusion. Chronically infected glial cells control virus production by a cell-specific mechanism using nef protein induction and may thus represent a virus reservoir in the brain.

W.C.P.92 NEUTRALIZING AND ENHANCING ANTIBODIES IN DIFFERENT STAGES OF HIV-INFECTION

D. Tóth F.*, Szabó, B.*, Ujhelyi, E.**, Horváth, A.***, Füst G.**, Bánhegyi, D.**** et al.
*Inst.Microbiol.Univ.Med.School, Debrecen, **Natl.Inst.Haematol.Blood Transf. Budapest, ***Natl.Inst.Dermat.Venerol., ****Municip. László Hosp.Inf.Dis., Budapest, Hungary

Objectives. Enhancing antibodies (ENH AB) were reported to be present in the blood of HIV-infected patients and believed to influence the course of infection. In the present study the incidence of these antibodies were investigated in parallel to that of the neutralizing antibodies (NEU ABS). Methods. Reclustering assay on MT-4 cells was used for detection of ENH and NEU AB. HIV-seropositive (HIV+) sera were filtered through 50 nm filters and heat treated (56°C, 30 min). The same sera were tested for NEU and ENH AB after 1:1 mixing with fresh, complement-sufficient (CS) pooled HIV-seronegative serum (CS-serum). Results. The following results were obtained in the 39 serum samples tested:

Group	No sample tested	NEU AB in heated serum	NEU AB in CS-serum	ENH AB in CS-serum
asympt.HIV+	19	19	8	4
ARC, AIDS	20	11	0	12

Conclusion. These findings support the results of Robinson et al. (1988) on the presence of complement-dependent ENH AB in HIV-infected persons and suggest that their appearance in parallel to the loss of NEU AB may signal a bad prognosis.

W.C.P.93 LOW PLASMA CYSTEINE AND ELEVATED GLUTAMATE LEVELS IN HIV-1+ PATIENTS MAY CONTRIBUTE TO LOSS OF T CELL FUNCTIONS.

Dröge, Wulf, Frey, H. and Eck, H.-P.
Institute of Immunology and Genetics, German Cancer Research Center, Heidelberg, F.R.G.

Objective. To investigate the hypothesis that the immunological deficiency may be partly the consequence of a virus-induced metabolic disorder.
Methods. The plasma glutamate and thiol (cysteine) levels of groups of HIV-1 infected patients with different stages of disease have been studied; and the influence of abnormal extracellular concentrations of glutamate and cysteine on lymphocyte and macrophage functions has been analyzed in vitro.
Results. HIV-1 infected patients have markedly reduced plasma cysteine and elevated glutamate concentrations. Similar variations of the extracellular cysteine or glutamate concentrations have profound effects on proliferative responses in lymphocyte cultures. Lymphocyte responses are augmented by cysteine and inhibited by elevated concentrations of glutamate or by its structural analogues quisqualate and N-methyl-D-aspartate (NMDA) but not with kainate. This suggests that glutamate may act on cell surface receptors analogous to the quisqualate and NMDA sensitive excitatory glutamate receptors in the vertebrate central nervous system. Elevated extracellular glutamate levels inhibit also the capacity of macrophages, monocytes and fibroblasts to release cysteine into the extracellular space.
Conclusion. A metabolic defect in HIV-1 infected patients may cause an insufficient supply of cysteine for lymphocytes and may thereby be responsible -at least in part- for the insufficient immunological reactivity.

W.C.P.94 IDENTIFICATION OF PHENOTYPIC ULTRASTRUCTURES OF LYMPHOCYTES REACTING WITH AUTO-ANTIBODIES IN AIDS

Pekovic, Drasko*, Garzon, S. **and Strykowski, H.** N. Lapointe,*** and Ajdukovic, D. ****
*AIDS Research Centre, Biomedco Canada Inc., Canada, ** Faculté de Médecine de l'Université de Montréal, *** St.Justine Hospital, ****Institut Armand Frappier, Montréal, Québec, Canada

Understanding the mechanisms of immune suppression and lymphocyte depletion in HIV-positive patients is perhaps central to the understanding of the initiation and the evolution of AIDS. There is general agreement that the etiologic agent of AIDS is HIV but the precise mechanisms by which the virus affects the immune devastation are unknown. Anti-lymphocytes auto-antibodies (Ab) are lympholytic *in vitro* and undoubtedly contribute to the destruction of lymphotic tissues *in vivo*. Present studies aim at determining the specificity of anti-lymphocytes auto-Ab in AIDS.

HIV antigens were identified in peripheral blood lymphocytes (PBL) obtained from 94 patients at different stages of HIV infection using immunofluorescence (IF) and immuno-electron microscopy (IEM) techniques. *In vivo* studies of the phenotype of HIV-containing lymphocytes by double labelings showed that OKT4+ cells are the principal target of the virus. Almost all infected PBL and approximately 30 percent of uninfected PBL displayed Ab-C3 complexes on the cell surfaces as demonstrated by IF. Sera from HIV-positive patients contain Ab reacting with cell membranes and intracellular structureds of PBL from normal subjects, as demonstrated by IEM. Double immunogold labelings showed that the pattern of reaction of serum Ab is different among phenotypic lymphocyte populations and that this pattern changes with the evolution of HIV infection.

The presence of Ig-C3 complexes on a high percentage of HIV-positive or negative PBL suggests that the Ab-C-mediated lympholysis may represent a major mechanism of lymphatic tissue destruction in AIDS.

W.C.P.95 LONGITUDINAL STUDY OF HIV ANTIBODY RESPONSES OF INFANTS BORN TO SEROPOSITIVE WOMEN IN ZAIRE

Katzenstein, David*; Hendry, R.M.,*; Nsa, W.**; Ryder, C.** Brown, C.**; Quinn, T.C.**; et al.
LRR, DV, *Center for Biologics Evaluation and Research, FDA and NIAID, NIH, Bethesda, MD, USA, **Projet SIDA Kinshasa, Zaire

Objective. To determine if neutralizing antibodies (NA) or antibodies on isotype specific Western Blots (ISWB) are associated with transmission of HIV from pregnant women to their infants.
Methods. Paired maternal and infant sera were collected at the Mama Yemo Hospital in Kinshasa, Zaire. Sera were obtained every 3 months from infants born to HIV seropositive women. Sera were studied from 2 groups based on infant's outcome; healthy at 18 mo. (Gp 1), AIDS at 12-18 mo. (Gp2). ISWB were developed for IgG, IgG 1-4, IgA, or IgM. NA were assessed by inhibition of syncytia formation using HIV_{IIIB}.
Results. Maternal sera from both groups reacted strongly with all HIV antigens in IgG blots. Among Gp1 infants, 1/8 had anti-HIV IgM Ab and 4/8 developed new IgG Ab. Among Gp 2 infants 8/10 had IgM and 9/10 had IgG by 9-12 mo. of age. NA were detected in most maternal sera at titers from 1:8 to 1:256. Significantly, 8/10 Gp 2 infants developed NA compared to 1/10 Gp 1 infants ($p < .03$, Fisher's exact test).
Conclusions. Infants with NA and evolving ISWB patterns had AIDS by 18 months, although 5/8 healthy infants had ISWB suggesting HIV infection. IgM responses to HIV were not observed in the first 6 months of life, even in infants who had other evidence of infection. We did not find a relationship between maternal NA and transmission of infection to infants.

W.C.P.96 NEUTRALIZING ANTIBODY IN SEROPOSITIVE SUBJECTS FROM AFRICA, SOUTH and NORTH AMERICA AGAINST 4 DIVERGENT STRAINS OF HIV

Katzenstein, David*; Vujcic, L.*; Latif, A.**; Galvao, B.***; Halsey, N.****; Quinnan, G.V.*; et al. LRR, DV, *Center for Biologics Evaluation and Research, FDA, Bethesda, MD, **Univ. of Zimbabwe, Harare, Zimbabwe, ***Johns Hopkins School of Pub. Health, Balt., MD, USA, ****Fiocruz, Brasil

Objective. To assess cross reactivity of neutralizing antibodies (NA) against different isolates of HIV in serum of HIV infected individuals from North and South America and Africa.
Methods. Virus isolates HIV-IIIB, RF, MN, and Z-2 were tested with sera from Haiti, the U.S., Brasil, Zaire, and Zimbabwe. NA titers of sera were the reciprocal of the serum dilution that decreased the number of syncytia by >50% in Molt-3 cells.
Results. None of 50 sera from seronegative subjects had NA, while sera from seropositive subjects had NA against HIV_{MN}, HIV_{IIIB}, HIV_{RF} and HIV_{Z2} in 94%, 80%, 56%, and 57% respectively. Asymptomatic subjects (AS) were less likely to have NA than subjects with AIDS or ARC (SYM) (87/115 AS vs 72/86 SYM for HIV_{IIIB} and 56/114 vs 53/70 for HIV_{RF}, $p < .016$, X^2). Analysis of individual geographic cohorts demonstrated similar geometric mean titers (GMT) of NA against each isolate, although the GMT was significantly higher against HIV_{MN} in 60 U.S. sera (1929) than in 40 Zairean (475), 53 Zimbabwean (733) or 50 Haitian (372) sera ($p \leq .05$, Student's T).
Conclusion. Symptomatic HIV seropositive subjects have higher titers of NA against HIV compared to AS. NA in seropositive subjects in the Americas and Africa have broadly cross reactive NA against genetically divergent strains of viruses from the U.S., Haiti, and Africa.

W.C.P.97 SPECIFIC DEFECT IN TISSUE FACTOR EXPRESSION IN MONOCYTES FROM AIDS PATIENTS

Lathey, Janet L.*; Agosti, J.M.**; Carey, L.**; Edgington, T.S.*; Oldstone, M.B.A.*; and Nelson, J.A.*.
*Research Institute of Scripps Clinic, La Jolla, California, **University of Washington, Seattle, Washington, USA

Monocytes/macrophages can be infected with human immunodeficiency virus (HIV). Such cells are important in regulating immune and coagulation systems. Hence, infection of the host may alter these cells, disrupting the expression of modulating factors. Thus, tumor necrosis factor (TNFα), tissue factor (TF), and interleukin I-ß (IL-1ß) mRNAs were evaluated in monocytes from HIV seropositive patients. RNA was extracted from monocytes with or without LPS stimulation, and hybridized with cDNA probes for TNFα, TF, and IL-1ß. A significant depression (66%) in TF mRNA expression in monocytes from AIDS patients occurred after LPS stimulation, contrasting the "normal" responses observed for TNFα and Il-1ß. Induced TF mRNA reduction was also observed to a lesser degree in ARC patients (20%) but not in asymptomatic seropositives. A similar pattern was found for TF procoagulant activity in the same cells. TF is necessary for the initiation of the coagulation protease cascade, leading to thrombin production and fibrin deposition, important effector components for a delayed hypersensitivity reaction (DTH) and an inflammatory response. Indeed, DTH responses were concordantly reduced in study patients. Thus, TF's selective reduction may be related to the diminished resistance to secondary infections observed in ARC and AIDS patients.

W.C.P.98 ANTIBODIES TO gp41 peptide (HIVIS, aa 583-599) DO NOT CORRELATE SIGNIFICANTLY WITH PROTECTION FROM DISEASE IN HIV INFECTION.

Chiengsong-Popov, Rachanee.; Caun, K.; Panagiotidi, C.; Blomberg, J. and Weber, J.
Department of Infectious Diseases, Royal Postgraduate Medical School, London W12 0NN, University of Lund, Sweden and St Mary's Hospital, London W2, UNITED KINGDOM

Objective. To examine the association between antibodies to a putatively immunosuppressive domain on gp41 (pHIVIS, amino-acids 583-599) and disease outcome in a cohort of subjects infected by HIV-1.
Methods. Peptides derived from HIV-1 gp41 were made as previously described (Klasse, Pipkorn and Blomberg, PNAS 1988;85). Peptide 583-599 is partially homologous to the p15e domain on C-type retroviruses, which is thought to be immunosuppressive in vitro. Control peptides were derived from an immunogenic conserved domain on gp41, amino-acids 586-606. Antisera were assayed in a direct anti-globulin ELISA, with batteries of positive and negative controls. Sera were derived from a cohort of homosexual men followed prospectively, and well defined clinically, over a six year period.
Results. Antibodies to the peptides were found in the following proportions in these patients, grouped by clinical outcome at 6 years post infection.

	Asymptomatic	ARC	AIDS
HIVIS	3/14	1/13	2/8
Control	12/14	4/4	7/8

Conclusions. These results suggest that there is no statistical association between antibodies to the HIVIS peptide, and protection from disease progression in HIV infection, in this cohort of subjects; these results will be compared to the original results of Klasse et al.

W.C.P.99 AUTOIMMUNITY AGAINST NEUTROPHILS AND THROMBOCYTES IN DIFFERENT STAGES OF HIV-INFECTION

R.J.L. Klaassen*, J.W. Mulder**, A.B.J. Vlekke*, J.M.A. Lange**, A.E.G. Kr. von dem Borne*. *Central Laboratory of the Netherlands Red Cross Blood Transfusion Service and **Municipal Health Service, P.O. Box 9190, Amsterdam, the Netherlands.

Objective. To get insight in the role of autoantibodies against neutrophils and platelets in the pathogenesis of HIV-infection.
Methods. We investigated the prevalence of these autoantibodies in subjects in different stages of HIV-infection [Group3 (n=13) asymptomatic with T4> 0.5x10^9/l; Group4 (n=27) asymptomatic with T4< 0.5x10^9/l; Group5 (n=9) with ARC(CDC 4A); Group6 (n=12) with opportunistic infections (CDC 4C1/4C2); Group7 (n=10) with malignancies (CDC 4D)] and in heterosexuals (n=19, group1) and promiscuous HIV- homosexuals (n=20, group2). Presence of the autoantibodies was determined by immunofluorescence. The specific autoantibody nature was investigated by preparation of acid-eluates from the cells.
Results. Platelet- and neutrophil-autoantibodies were almost absent in group 1 and 2, but frequently found in asymptomatics (between group 3 and 4 no difference) ($p<0.002$, <0.05 respectively, as compared to HIV- individuals). In the majority of symptomatics (between group5, -6 and -7 no difference) antibodies against platelets and neutrophils were found ($p<0.002$ and <0.005 respectively, as compared to the asymptomatics). However, no correlation between the presence of the autoantibodies and the cell-count was observed.
Conclusion: In this study the presence of autoantibodies against platelets and neutrophils is limited to HIV-infection and related to the stage of HIV-infection, which suggests a role in pathogenesis.

W.C.P.100 HIV TARGET CELLS IN TESTES AND EPIDIDYMIDES FROM AIDS PATIENTS

Elbrock Axel*, Vazeux R**, Hénin D***, Hadchouel M*, Katlama C***, Aaroun M* et al.
* INSERM U56 and Centre Hospitalier Universitaire, Bicêtre, France; **Institut Pasteur, and *** Centre Hospitalier Universitaire Salpêtrière, Paris, France.

Objective: To elucidate possible mechanisms of sexual HIV transmission, we have studied mononuclear cells in testes and epididymides from AIDS patients and searched for HIV antigen expression.
Methods. Thirty-two testes (27 AIDS patients, 5 controls) and 17 epididymides (15 AIDS, 2 controls) were obtained post-mortem. Frozen sections were incubated with monoclonal antibodies to CD3, CD4, CD8, monocyte/macrophages, HIV P18 and P 24, and revealed by an indirect immunoperoxidase technique. Standard pathological examination was performed.
Results. No lymphocyte nor macrophage was found in the seminiferous ducts of controls. Macrophages could be found in the epithelium and ducts of control epididymides, however. HIV antigens were found in the testes of two patients in interstitial macrophage-like cells. Very high numbers of CD4+ macrophages were found in the testes and epididymides of most patients, occasionally in the seminiferous and epididymal ducts and constantly in the epididymal epithelium. High numbers of CD3+ cells, mostly CD8+, were also observed with a similar distribution. There was no pathological evidence of opportunistic infection responsible for mononuclear cell infiltration.
Conclusion. Although HIV antigenic expression was found in only two patients, abnormally high numbers of CD4+ macrophages were found in the testes and epididymides of AIDS patients, often in very close contact with germ cells. This suggests that CD4+macrophages play an essential role in the sexual transmission of HIV and raises the possibility of contamination of germ cells by direct contact with CD4 macrophages.

W.C.P.101

W.C.P.102 NOVEL SPOROZOITE SURFACE LECTIN IN CRYPTOSPORIDIUM PARVUM

Thea, DM; Pereira, MEA; Sterling, C; Keusch, GT.
New England Medical Center, Boston, MA, USA

Objectives: To determine whether or not the sporozoite (S) stage of *C. parvum* (CP) produces a sugar binding lectin, to purify and characterize this protein, and to determine its role in pathogenesis of CP infection.
Methods: CP oocyts (O) were obtained from the stool of AIDS patients, purified by gradient centrifugation, and allowed to excyst *in vitro*. A hemaglutination (HA) assay was developed using intact-S, S-sonicates, intact-O, or O-membranes. S were solubilized in 0.5% triton-X-100 plus protease inhibitors and centrifuged at 100,000 g for 90 min to localize HA in the soluble and membrane fractions. Binding specificity was studied by HA inhibition in the presence of over 20 simple and substituted mono and disaccharides, and glycoproteins. Cation and pH requirements were also determined. Lectin purification was attempted by affinity chromatography.
Results: HA was present in intact S and increased 128-fold in sonicates. Isolated O had less HA activity than S, and O membranes showed none. The best inhibitor of HA was bovine submaxillary mucin (BSM). HA was optimal at pH 6, did not require divalent cations, and was present in S membranes and not in cytosol or cytoskeletal fraction. Intact S formed rosettes around erythrocytes, indicating a surface location of the HA. Partial purification of the lectin has been achieved on a BSM-Sepharose 4B column.
Conclusion: we have identified a novel *C. parvum* lectin, which is found on the sporozoite surface (the infective form of the parasite). The most effective *in vitro* hapten inhibitor tested was BSM. The *in vivo* receptor and role of lectin in attachment/invasion of host cells is not yet known.

W.C.P.103 A POSSIBLE BLOCK OF VIP DEPENDENT NEURONAL SURVIVAL BY GP120 IN AIDS DEMENTIA COMPLEX

Kimura-Kuroda,J., Yasui,K. and Iwasaki,T..
Dept. of Microbiology, Tokyo Metropolitan Institute for Neurosciences, 2-6, Musashidai, Fuchu-shi, Tokyo, 183, JAPAN.

Objective. Vasoactive intestinal peptide (VIP) has been shown to increase neuronal survival in mouse brain culture (Brenneman,D.E.,et al., PNAS, 83:1159, 1986), and its amino acid sequence shows some homology with a sequence of the gp120, called peptide-T. Pert et al. have reported that the VIP attenuated the neuronal cell death caused by gp120 in mouse hippocampal cultures (Brenneman,D.E., et al., Nature, 335:639, 1988). To determine the mechanism of VIP dependent neuronal survival, We studied the effects of VIP and/or peptide-T on rat brain cultures, and tried to clarify the pathogenesis of AIDS dementia complex.
Methods. Neural cells of hippocampus or cerebral cortex were obtained from 18-19 day old fetal rat. VIP and/or peptide-T was added to the culture on day 0 or 7. After 12 days, the cells were stained with specific antibodies to neuron or astrocyte, and the survival of neurons was measured.
Results. Addition of 0.1 nM VIP to brain culture produced a significant increase of neuronal survival. On the other hand, 100 nM peptide-T decreased the number of neurons. Peptide-T (100 nM) antagonized the function of VIP (0.1 nM). They did not affect the numbers and shapes of astrocytes, the major glial cells in culture.
Conclusion. We confirm that VIP is important for neuronal survival in cultures of hippocampus and cerebral cortex of rat. The results suggest that peptide-T binds to VIP receptors and antagonizes the VIP-dependent neuronal survival. Possibly, the gp120 of HIV also blocks VIP-dependent neuronal survival, and the resulting death of functional neurons causes the AIDS dementia.

W.C.P.104 THE EARLY STEPS OF T LYMPHOCYTE ACTIVATION ARE INHIBITED BY HIV-2, STLV-III, AND DIFFERENT STRAINS OF HIV-1.

B.HOFMANN, P.NISHANIAN, P.INSIXIENGMAY, J.L.FAHEY.
UCLA School of Medicine, Los Angeles, CA. U.S.A.

Objective. To show the suppressive effect of different HIV isolates on T lymphocyte proliferation and show the effect of HIV on lymphocyte activation.
Methods. Addition of inactivated HIV preparations to PHA stimulated cultures of lymphocytes.
Results. We and others have earlier reported a suppressive effect of a HIV lysate on lymphocyte proliferation. Here we have extended these studies using different beta-propriolactone inactivated preparations of STLV-III, HIV-2, and four different isolates of HIV-1, and showed that these all had a suppressive effect on T lymphocyte proliferation. Further investigation of a preparation of beta-propriolactone inactivated HTLV-IIIB showed that the addition of this preparation to cultures of peripheral blood lymphocyte severely decreased the proliferation induced by both CD3 (T cell receptor) and CD2 (alternative pathway) monoclonal antibodies as well as the responses induced by phorbol esters (PMA) or the ionophore A23187, whereas the responses to different combinations of PMA/A23187 were either suppressed or enhanced. Studies of purified CD4 and CD8 T cells showed that addition of HIV inhibited the response to PHA in both cell subsets. The inhibitory effect of inactivated HIV seem to be on the early steps of activation since pulsing with HIV for less than five minutes followed by washing was sufficient to inhibit the proliferation in response to PHA. However, if HIV was added to already stimulated cells no inhibitory effect was found. Flow cytometry analysis of PHA stimulated lymphocytes cultured with or without HIV showed that HIV decreased the development of granularity. Further, the expression of IL-2 receptors and transferrin receptors were decreased on both CD4 and CD8 cells. Cells expressing IL-2 receptors, especially the bright type, were lacking. This indicates a decrease in the number of receptors expressed. Preliminary experiments showed that the increase in free intracellular Ca2+ after stimulation with PHA was not inhibited by addition of HIV and that HIV alone did not cause an increase in free intracellular Ca2+. Studies are in progress to determine the effect of HIV on the intracellular pathways of protein kinase C.
Conclusion. The current studies indicate that HIV has a suppressive effect on both CD4 and CD8 T lymphocytes independent of infectivity and that this effect occurs in the early steps of activation and may be related to the protein kinase C pathway. The results with PMA/A23187 may propose that the inhibition was due to preactivation.

W.C.P.105 VIRAL ANTIGEN STIMULATION OF THE SECRETION OF HUMAN MONOKINES CAPABLE OF REGULATING HIV-1 EXPRESSION.

Clouse, Kathleen A*; Washington, I. Robbins, Fernie, B., Ostrove, J.M., Fauci, A.S
*Georgetown University, Washington, D.C.; *LIR, NIAID, NIH, Bethesda, MD. U.S.A.

Objective. We have previously described model systems for cytokine-induced regulation of HIV-1 in chronically infected T lymphocyte and promunocyte clones. Our current objective was to determine whether viral antigens can stimulate human macrophages to secrete monokines capable of upregulating HIV expression in infected cells.
Methods. Chronically HIV-1 infected T cells (ACH-2) or promonocytes (U1) were tested for inducibility with monokine-enriched supernatants obtained following stimulation of elutriated human monocytes with bacterial lipopolysaccharide or purified, inactivated viruses (viral antigens). Induction of HIV expression was monitored by reverse transcriptase activity.
Results. We found that certain herpes-group viruses, including cytomegalovirus and Epstein-Barr virus augment HIV expression by stimulating monokine production. Other herpes viruses, such as herpes simplex virus, varicella zoster virus, and human herpes virus-6 were unable to function in this capacity. When non-herpes group viruses were tested, we found that human adenovirus, hepatitis B virus, and vaccinia virus all failed to stimulate the production of monokines capable of activating HIV in the chronically infected cell lines. Furthermore, HIV-1 can augment its own expression by inducing the secretion of monokines which upregulate HIV expression in the infected cell lines. Monokine production mediated by viral antigens was not attributable to contaminating endotoxin.
Conclusion. These studies provide a model to determine whether other opportunistic infections may induce the expression of HIV by indirect mechanisms, such as the stimulation of cytokine production.

W.C.P.106 EFFICIENT HIV ISOLATION FROM HEALTHY SEROPOSITIVE INDIVIDUALS USING NORMAL MONOCYTE TARGETS: IMPLICATIONS FOR HIV CELL TROPISM

Poli, Guido, Massari, F.E., Schnittman, S.M., Lane, H.C., Fauci, A.S. LIR, NIAID, NIH, Bethesda, MD. U.S.A.

Objective. To determine the efficiency of viral isolation and in vivo cellular source of HIV from peripheral blood mononuclear cells (PBMC) of healthy seropositive individuals.
Methods. PBMC from healthy, HIV-seropositive individuals were cocultured with either allogeneic PHA blasts or monocytes obtained by elutriation. Supernatants were assayed for reverse transcriptase activity and p24 antigen. Cells were seperated into highly purified lymphocyte and monocyte fractions by rosette and FACS techniques. Polymerase chain reaction (PCR) was used to amplify proviral DNA.
Results. When HIV isolation was attempted onto PHA blasts or monocyte targets we found: in 1/23 (4%) patients, HIV could only be isolated by PBMC coculture with PHA blasts; in 7/23 (30%) patients, virus could only be isolated when PBMC were cocultured with monocytes and in 5/23 (22%) patients virus could be isolated using both systems. Leukopheresis was performed on five of the seven patients whose viral isolation was accomplished only on monocytes. PBMC from these individuals were fractionated by rosette and FACS techniques (99% purity) and PCR was performed on each fraction. Despite the fact that virus could only be isolated onto monocytes, 4 out of 5 individuals had proviral DNA detectable only in their T cells, and in the other individual in both monocyte and lymphocyte fractions.
Conclusion. In healthy seropositive individuals, HIV could be isolated with greater than 50% efficiency using monocytes as targets as compred to 26% efficiency when using PHA blast targets. In 4 out of 5 patients from whom virus could only be isolated onto monocytes viral DNA could be detected in vivo only in T cells. Thus, in vitro monocyte tropism does not necessarily indicate in vivo monocyte infection with HIV.

W.C.P.107 TNF-α CAN INDUCE THE EXPRESSION OF HIV FROM CHRONICALLY INFECTED CELLS IN AN AUTOCRINE FASHION.

Poli, Guido, Justement, J., Kinter, A., Clouse, K.A., Folks, T.M., Fauci, A.S. et al. LIR, NIAID, NIH Bethesda, MD; Georgetown University, Washington, DC. U.S.A.

Objective. To investigate the hypothesis that tumor necrosis factor alpha (TNF-α) can induce the expression of HIV in chronically infected cells in an autocrine fashion.
Methods. The T lymphocytic (ACH-2) and promonocytic (U1) cell lines are chronically infected with HIV-1, and the constitutive low level expression of HIV can be potently induced (10-20 fold increase of reverse transcriptase) by treatment with phorbol esters (PMA) or TNF-α. We therefore investigated the possibility that ACH-2 and U1 cells could synthesize and secrete TNF-α (as assessed by a specific Biokine kit) and could express TNF-α molecules on the plasma membrane (by immunofluorescent stain and FACS analysis). We also studied the expression of TNF receptors (R) on ACH-2 and U1 cells and on their parental uninfected cell lines in unstimulated and PMA stimulated conditions.
Results. TNF-α is not detectable in supernatants of unstimulated ACH-2 and U1 cells, but significant amounts (150 pg/ml) of TNF-α are present in the supernatants of both cell lines after 24 to 48 h stimulation with PMA 10^{-7} M, in parallel with the expression of HIV. Furthermore, TNF-α is present on the plasma membrane of ACH-2 cells after treatment with PMA. Of interest, PMA stimulation of ACH-2 and U1 cells resulted in the upregulation of TNFR (2-5 fold) whereas the levels of TNFR were found unchanged or downmodulated in the uninfected parental cell lines that had been exposed to PMA.
Conclusions. TNF-α can act as an autocrine cytokine capable of inducing the upregulation of viral expression in cells of lymphocytic and promonocytic origin that chronically carry integrated HIV provirus.

W.C.P.108 QUALITATIVE DIFFERENCES IN HIV-1 AND HIV-2 INFECTIONS OF A PANEL OF $CD4^+$ T CELL CLONES

Poli, Guido, Duh, E., Rabson, A., Clavel F., Fauci, A.S. LIR, LMM, NIAID, NIH, Bethesda, MD. U.S.A.

Objective. To investigate the patterns of HIV-1 and HIV-2 infection in vitro in a panel of T cell clones expressing comparable amounts of CD4.
Methods. A panel of T cell clones were obtained from the CEM-derived A301 cell line. Four clones expressing comparable levels of CD4 were selected from an original panel of 42 because of their differences in response to HIV-1 and HIV-2, as measured by reverse transcriptase activity (RT) released in the culture supernatant and by the kinetics and extent of cytopathic effect (CPE). Cell extracts were made from the four clones and tested for the presence of transcription factors by gel mobility shift assays for NF-kB and Sp-1.
Results. Two out of four clones were "fast/high" (peak RT activity 5000-9000 cpm/μl observed between day 4 and 7 post-infection) and two were" slow/low" (peak RT below 2000 cpm/μl, observed between day 10 and 18 post-infection) in terms of patterns of infection with both HIV-1 and HIV-2. Phenotypic analysis of multiple surface markers did not show any evident correlation with the infection patterns described. HIV-1 and HIV-2 showed similar efficiency of infection in terms of RT and downmodulation of the CD4 molecule. The only difference between HIV-1 and HIV-2 was that HIV-2 infection was frequently associated with a second burst of viral replication occurring in the absence of CPE in cells that had already lost the CD4 molecule from the plasma membrane. When cell extracts from the four clones were examined, no differences were noted in terms of binding to Sp-1 specific sequences. On the other hand, only 1 out of 2 "fast/high" responder clones showed measurable binding to NF-kB.
Conclusion. Significant biological differences were observed among T cell clones expressing comparable levels of CD4 molecules in response to HIV-1 and HIV-2 infection. Different constitutive levels of NK-kB transcription factor could partially explain these results.

W.C.P.109 GM-CSF INHIBITION OF SUSCEPTIBILITY OF M-CSF TREATED HUMAN MONOCYTES TO IN VITRO INFECTION WITH HIV.

Massari, Ferdinand, Poli, G., Fauci, A.S., LIR, NIAID, NIH, Bethesda, MD. U.S.A.

Objective. To determine the effects of granulocyte-macrophage colony stimulating factor (GM-CSF) on the susceptibility of M-CSF treated monocyte cultures to HIV infection.
Methods. Peripheral blood monocytes (PBM) were purified by elutriation (95% purity), resuspended in medium containing 1000 U/ml of M-CSF in the absence or presence of 10 U/ml GM-CSF. After 12-14 days of culture, cells were challenged in vitro with different strains of HIV and the cultures were monitored for 30-90 days for the production of HIV p24. The ability of monocytes to proliferate and their phenotype were also assessed.
Results. Monocyte cultures maintained in the presence of M-CSF showed a productive infection with different strains of HIV. The presence in culture of GM-CSF before HIV infection resulted in the complete block of HIV expression with all the strains tested thus far. This inhibitory effect was not observed if GM-CSF was added after the infection with HIV. GM-CSF caused a dramatic increase of ^{3}H-thymidine uptake by monocytes when compared to untreated (100 fold increase) or M-CSF treated cells. The presence of GM-CSF did not affect the expression of the CD4 molecule on the plasma membrane of cultured monocytes.
Conclusion. GM-CSF is a potent inhibitor of the susceptibility of M-CSF treated monocytes cultures to HIV infection. This effect is inversely correlated with the ability of GM-CSF to stimulate monocyte proliferation. Further, the inhibitory effect of GM-CSF is not mediated through a downregulation of the CD4 molecule on the monocyte membrane.

W.C.P.110 THYMUS INVOLVEMENT IN AIDS PATHOGENESIS: IN VITRO STUDIES OF THYMUS INFECTION.

De Rossi A.*,Calabrò M.L.*,Bernardi D.*,Panozzo M.* ,Tridente G.**,Chieco-Bianchi L.*.
*Institute of Oncology, University of Padova, **Inst. of Immunopathology,University of Verona, ITALY

Objective. In vivo observations suggest a thymus involvement in AIDS pathogenesis, but whether thymocytes constitute a direct target of HIV infection is under debate. To study this aspect, we infected total and fractionated thymus cell populations in vitro with HIV-1, strain HTLV-IIIB.
Methods. Kinetics of infection were evaluated by assessing R.T.activity and viral antigen expression. Viral genome in the infected cells was detected by Southern blot and dot blot techniques, using pBH10 probe. Viral transactivation activity was evaluated by CAT assay, in HIV-1 infected cells, 72 hrs after transfection with pl5CAT.
Results. Normal thymic lymphocytes and the immature CD1+CD4+CD8+ enriched fraction, retrieved by panning, were permissive to HIV-1 infection and, specifically, immature CD1+ cells showed a marked susceptibility to viral infection and replication. When total thymic lymphocytes or CD1+ cells were infected in parallel with autologous PBL or peripheral CD4+ lymphocytes, respectively, thymic cells were more susceptible to viral replication and transactivation.
Conclusions. Thymic CD4+CD8+ cells, which most likely represent the precursors of mature peripheral CD4+ and CD8+ lymphocytes, are very susceptible targets for HIV-1 infection. The implications of this finding may be relevant in the pathogenesis of AIDS.

W.C.P.111 INHIBITION OF HIV-1 REPLICATION WITH REVERSE TRANSCRIPTASE INHIBITING (RTI) ANTIBODY IN LYMPHOCYTE CULTURES

Takasaki, Tomohiko*;Imagawa, D.*; Lee, M.*; Kusakabe, H*; Sugita, K.***; Nishanian, P.**; Concepcion, N.*. *Harbor-UCLA Medical Center, Torrance, CA. **UCLA School of Medicine, Los Angeles, CA. U.S.A. ***Osaka Medical College, Japan and L.A. Multicenter AIDS Cohort Study (MACS)

Objective: Previous studies showed protective effect of RTI antibody in HIV-infected individuals, thus the effect of purified RTI antibody on HIV-1 replication in lymphocyte culture was determined.
Method: RTI antibody was purified from high titered human serum by affinity chromatography to sepharose 4B-200 coupled with purified RT protein. This purified RT antibody or high titered RTI serum was added to 6 x 10^6 donor PHA-stimulated peripheral blood lymphocytes (PBL) infected with HTLV-III b (1.5 x 10^5 virus particles). HIV replication was monitored by a P24 antigen capture ELISA assay (Abbott) of the culture supernatant. Donor human serum and borate-buffered saline served as controls.
Results: Addition of purified RTI antibody or high titered RTI serum to HIV-infected PBL cultures showed decreased virus replication compared to controls in 2 separate experiments.

Mean P24 Antigen in Culture Supernatant (ng/ml)

Days in Culture	High Titer RTI Serum	Purified RTI Ab	Borate-Buffered Saline	Donor Serum
9d	0	78.5	242.5	248.5
20d	0	308.5	418.5	>500.0

Conclusion: This study shows that RTI antibody to HIV inhibits virus replication in lymphocyte cultures. This RTI antibody therefore may play a role in preventing the progression of disease in HIV-infected individuals.

W.C.P.112 VIROLOGIC MARKERS OF CENTRAL NERVOUS SYSTEM HIV INFECTION IN HIV SEROPOSITIVE HOMOSEXUAL MEN WITHOUT NEUROLOGICAL SYMPTOMS.

Robert W Coombs, AC Collier, K Chaloupka, J Dragavon, HH Handsfield, L Corey et al. University of Washington, Seattle, WA, USA.

Objective. To determine the frequency of central nervous system (CNS) HIV infection in asymptomatic HIV seropositive homosexually active men.
Methods. Forty-four CDC class II and III patients without overt neurologic disease had peripheral blood mononuclear cells (PBMC), cell-free plasma, and cerebrospinal fluid (CSF) submitted for HIV culture. Serum and CSF HIV antibody were measured by enzyme-immunosorbent assay (EIA) (Genetic Systems) and confirmed by immunoblot; HIV p24 antigen (Ag) was measured by EIA antigen capture (Abbott).
Results. HIV was cultured from 40/44 (90%) PBMC, 7/44 (16%) plasma, and 24/44 (54%) CSF specimens after ≤28 days of culture. HIV was cultured from the CSF of 5/7 with plasma viremia (HIV+) versus 19/37 plasma HIV- patients (p=NS). HIV p24 Ag was detected at ≥30 pg/ml in 7/40 (18%) serum and 0/40 CSF specimens. The mean calculated ratio of serum/CSF HIV EIA antibody was lower for CSF HIV+ (2.58, CI 2.05-3.11) versus CSF HIV- (4.81,CI 3.15-6.47) specimens (p=0.013). Using a serum/CSF antibody ratio of 5.5, intrathecal HIV-specific antibody synthesis was found in 21/21 CSF HIV+ and 13/19 (68%) CSF HIV- specimens (p=0.014).
Conclusions. HIV infection of the CNS occurs relatively early after HIV infection, and was present in 37/44 (84%) CDC class II and III homosexual men without neurological symptoms. Plasma viremia was highly specific (90%) but not sensitive (21%) for CSF HIV isolation. CSF HIV p24 Ag also was insensitive for detecting CSF infection. The inability to isolate HIV from the CSF in 13/34 (38%) patients with increased intrathecal HIV antibody synthesis suggests either compartimentalized or restricted HIV replication in the CNS. Prospective studies are required to determine if this early detection of CNS HIV infection will predict progression to symptomatic neurologic disease.

W.C.P.113

IN VITRO INTERACTIONS OF HIV WITH NEURONS, ASTROCYTES AND MICROGLIAL CELLS

M. TARDIEU, C. HERY, D. BOESPFLUG, S. PEUDENIER, R.M. VAZEUX, D. GUETARD, L. MONTAGNIER
INSERM U 56, Institut Pasteur, Paris FRANCE.

Cultures containing human embryonic neurons, astrocytes and microglial cells, (as characterized by immunostaining) were established from spinal cord of 10-12 week-old embryos. Cultures enriched in microglial cells (60 % KiM+, non specific esterase + cells) were subsequently obtained. After infection with HIV1 (5 X 10^4 cpm of virus, 4 different isolates of HIV1, including one from CSF, 2 differents isolates of HIV2), neurons and astrocytes were morphologically unaltered and no evidence of viral replication was obtained. Cultured microglial cells replicate poorly HIV1 or 2. When 10^2 HIV1-infected U937 or HL60 cells (two cell lines of monocytes-macrophage lineage) were cocultured with uninfected spinal cord cultures in 35 mm petri dishes astrocytic lesions were induced which were not observed after cocultures of neurons and astrocytes with uninfected U937 or HL60 cells, infected lymphocytes, or supernatants of infected macrophages. An adherence of infected macrophages to astrocytes is required to induce lesions.

In conclusion : (1) in vitro, embryonnic human neurons and astrocytes are resistent to HIV1 or HIV2 infection (2) HIV infected cells from monocyte macrophage lineage can induce indirect morphological lesions on cultured astrocytes.

W.C.P.114 RAISED LEVELS OF CIRCULATING TUMOUR NECROSIS FACTOR-α/ CACHECTIN IN PATIENTS WITH ACQUIRED IMMUNODEFICIENCY SYNDROME: PATHOGENETIC IMPLICATIONS

Lähdevirta, J.*, Maury, C.P.J.**, Teppo, A-M.** and Repo, H.***.
*Aurora Hospital, Helsinki, **Fourth and ***Second Departments of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

Objective. Rapid ageing and wasting are characteristic features of acquired immunodeficiency syndrome. The mechanisms underlying the weight loss are not well known. Tumour necrosis factor-α/cachectin (TNF) is a mononuclear phagocyte-derived factor implicated in the pathogenesis of cachexia in chronically infected experimental animals.
Methods. TNF was measured by a specific radioimmunoassay in 53 serum samples from 39 subjects with human immunodeficiency virus infection.
Results. TNF levels were elevated in all 9 subjects with AIDS and in 5/9 with AIDS-related complex. In contrast none of the 8 asymptomatic subjects and only 2/13 in the lymphadenopathy syndrome group had elevated levels. In the follow-up samples from patients with AIDS and AIDS-related complex, marked fluctuations in TNF levels were noted, but initially elevated levels remained elevated.
Conclusion. Patients with AIDS have elevated levels of circulating TNF. Since TNF suppresses lipoprotein lipase in vitro the present results may be relevant with respect to the pathogenesis of cachexia in AIDS.

W.C.P.115 ANAEMIA AND LYMPHOPENIA IN HIV INFECTION: RELATION TO SERUM LEVELS OF TUMOUR NECROSIS FACTOR-α

Maury, C.P.J.* and Lähdevirta, J.**.
*Fourth Department of Medicine, University of Helsinki. **Aurora Hospital, Helsinki, Finland

Objective. Haematological abnormalities are common findings in patients with AIDS and AIDS-related complex. However, the underlying causes of the abnormalities are not well understood.
Methods. TNF levels in serum were measured by a double antibody radioimmunoassay in 37 HIV-seropositive subjects.
Results. Significant inverse relationships were found between serum TNF levels and haemoglobin values ($r = -0.83$, $p < 0.001$), as well as between TNF levels and peripheral erythrocyte ($r = -0.78$, $p < 0.001$) and lymphocyte ($r = -0.66$, $p < 0.001$) counts.
Conclusion. Since TNF suppresses the colony formation of erythroid and myeloid progenitor cells in bone marrow cultures and causes anaemia when administered to humans and experimental animals, the demonstrated relationship between TNF and cytopenia in HIV infection may be causal.

W.C.P.116 ~~REPLICATION OF HIV-1 GAG AND POL INSERTION AND~~ DELETION MUTANTS IN HUMAN CELL LINES

Heisig, Volker*; Jahn, G.** and Zagury, D.**.
*IMMI, ~~Hamburg~~, FRG. **Université P. et M. Curie, Paris, France.

OBJECTIVE. Development of retroviral vectors for human gene transfer. HIV-1 gene expression and virus production in established T4 lymphocyte lines containing incomplete provirus.
METHODS. We have constructed various HIV-1 mutants, twelve containing insertion linkers and twelve with deletions in the gag or pol regions giving rise to a frameshift. All constructs were derived from pU, a plasmid containing the complete HIV-1 proviral genome, a hygromycin B gene for selection and the 3'LTR with deletions in the -138 to -40 region. Cells were analysed using immunofluorescence assay (IFA), reverse transcriptase activity (RT), Southern and Western Blots.
RESULTS. All lymphocyte lines showed more than 60% cells positive when tested, using AIDS patient serum, one, two and five months after transfection. Supernatants were RT negative. When analysed by Western blotting the presence of p17, p24, p51, p55 and gp160 proteins was revealled in two cell lines, pU-H9 and a gag deletion mutant. Viral preparations from supernatants are RT negative even when separated by sucrose gradient.
CONCLUSION. The transfected plasmids are stably transfected and express viral proteins. All cell lines are RT negative but at present we do not know if the 3'LTR deletion is responsible. Two cell lines, that release particles into the supernatant, are WB positive for the pol protein.

W.C.P.117 IMMUNOHISTOCHEMICAL ANALYSIS OF GERMINAL CENTERS (GC) IN RECTAL BIOPSIES OF PATIENTS WITH HIV-1 INFECTION.

Racz, Paul*, Tenner-Racz, K**, Schmidt, H*, Hartmann*, Dietrich, H*, Popovic, M***.
*Institute for Tropical Diseases, Hamburg, Germany;
**A.K. St. Georg, Hamburg, Germany.
***National Cancer Institute, Bethesda, USA.

Objective: To investigate the role of the GC-s of the rectum in the pathogenesis of HIV we studied 33 rectal biopsies from patients with HIV-1 infection.
Methods: Detailed histological and immunohistological analyses of the rectal biopsies were performed.
Results: Immunohistochemical reactions revealed gag proteins within the GC-s. The network of follicular dendritic cells was often disrupted. An important characteristic was the decreased numbers of CD4 lymphocytes. A similar decrease was observed in the numbers of Leu7 positive cells. There were increased numbers of CD8 lymphocytes.
Conclusion: Our findings indicate that the GC-s are important reservoirs of HIV. CD4 lymphocytes and macrophages circulating through the the GC may become infected with HIV there. We suggest that HIV can persist in the GC of the rectal mucosa for long periods or can be transported to the regional lymph nodes via the lymphatic vessels. The lymphatics then, quite possible serve as thoroughfares for HIV-1.

W.C.P.118 EVIDENCE FOR INTRAFOLLICULAR VIRUSREPLICATION IN GERMINAL CENTERS OF LYMPH NODES OF CATS INFECTED WITH FeLV: AN ULTRASTRUCTURAL EVALUATION.

Tenner-Racz, Klara*, Noronha, F.**, Schmidt, H.***, Racz, P.***.
*A.K.St. Georg, Hamburg, Germany; **Cornell University, Ithaca, USA; ***Institute for Tropical Diseases, Hamburg, Germany.

Objective: Many cats infected with the feline leukemia virus develop follicular hyperplasia, severe immunodeficiency and die of opportunistic infections, very similar to human infection with HIV. Therefore we used the feline model to investigate the cellular mechanisms of the pathomorphology and pathogenesis.
Methods: Ultrathin sections of 33 lymph nodes among 5 cats infected and 1 control animal were taken 5 or 9 months after inoculation, according to standard methods.
Results: The ultrastructural changes of the very hyperplastic follicles revealed a high concentration of virus particles in the vicinity of follicular dendritic cells (FDC) as shown in HIV-Infection. FeLV was found to replicate in different cell types: lymphocytes, plasma cells, macrophages and FDC.
Conclusion: The results suggest that FDC, as antigen trapping cells, capture FeLV. Virions held on FDC infect different target cells. Quite possible that a genomic shift may occur at the time of transmission of the virus to a novel target, therefore, GC may be one of the anatomic sites where variants with altered cell tropism and pathogenicity may be generated.

W.C.P.119 ESTABLISHMENT OF A CELL LINE CHRONICALLY INFECTED BUT NOT PRODUCING HIV-1 FROM AN ASYMPTOMATIC SEROPOSITIVE SUBJECT.

Titti Fausto; Federico, M.; Borsetti, A.; Ceccarelli, L.; Verani, P. and Rossi, G.B.
Laboratory of Virology, Istituto Superiore di Sanità, Rome, Italy.

Objective. To study a) the latency and the chronicity of HIV-1 infection and b) the control of HIV-1 gene expression.
Methods. PBL from an asymptomatic HIV-1 seropositive and HTLV-1 seronegative (ELISA, W.B.) subject were cloned by limiting dilution in presence of IL-2. The past medical history of the subject was characterized by recessive LAS (3 years ago) with virus isolation from lymphnodes. Further attempts, even at time of cloning, to reisolate virus were negative, as determined by antigen capture and reverse trascriptase assays. Cell subset characterization was made using monoclonal antibodies anti-T and -B lymphocytes, monocytes and macrophages membrane antigens.
Results. Two cell clones (URS1, URS4) carrying but not expressing the HIV-1 genome were isolated. The two clones have been maintained in culture for >5 months. Both are negative for extracellular virus production. Clone URS4 shows giant cells and an absolute requirement for exogenous IL-2. Cytofluorymetric analysis indicated that both clones are not terminally differentiated. PCR-DNA analysis, using SK01, SK02 HIV-1 gag primers followed by hybridization using oligonucleotide probes specific for gag region, was positive. Preliminary PCR-RNA analysis indicated the absence of active transcription of HIV-1 genome.
Conclusion. Cells with an integrated but not expressed HIV-1 genome are present in an asymptomatic seropositive individual. Further biological, immunological and molecular characterization of these clones is in progress.

W.C.P.120 INCREASED PRODUCTION OF ARACHIDONIC ACID METABOLITES (PROSTAGLANDIN E_2 AND THROMBOXANE B_2)BY MONOCYTES FROM DRUG ADDICTS (IVDA) INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS.

Fernández-Cruz, Eduardo; Zabay, J.M.; Longo, N.; Gómez, G.*; Roselló, J.*; Gelpí, E.* et al.
Hospital General "Gregorio Marañón", Madrid, Spain. *Centro de Investigación y Desarrollo del C.S.I.C., Barcelona, Spain.

We have analyzed the production of PGE$_2$ by monocytes from 19 IVDA with different clinical manifestations of HIV infection and from 16 healthy normal individuals or HIV-negative IVDA. The quantification of PGE$_2$ and TxB$_2$ from culture supernatants of purified monocytes was performed by high performance liquid chromatography and radioimmunoassay. The results showed that in the AIDS group 5 of 11 patients showed PGE$_2$ levels (736,419,208,372,1863 pg/ml) higher than the mean + 2 SD values from healthy controls (73 ± 21 pg/ml). This group with increased production of PGE$_2$ included: 3 patients with AIDS and opportunistic infections (OI), 1 patient with AIDS without active OI and 1 patient with AIDS-subgroup A. We also studied 8 patients with different clinical expressions of disease without AIDS. One of 8 patients showed PGE$_2$ levels (567 pg/ml) higher than the mean + 2 SD values from controls. This patient was asymptomatic but had low CD4 counts. In all cases synthesis and secretion of PGE$_2$ was inhibited by addition of indomethacin. Similar results were obtained regarding synthesis and release of TxB$_2$. We also tested the effect of concentrations of PGE$_2$ comparable to those released by monocytes from AIDS patients on the production of interleukin 2 (IL-2) by normal PHA-stimulated PBMC. The higher concentrations of PGE$_2$ produced by monocytes from AIDS patients induced a marked suppresion of IL-2 production. HIV infection may alter the synthesis and secretion of PGE$_2$ in monocytes which may lead to the immune dysfunction of AIDS.

W.C.P.121 Ras oncogene co-transfection induces transactivation of the HIV-LTR through NF-KB binding site

Arenzana-Seisdedos, Fernando; Israel,N; Bachelerie,F.; Hazan,U.; Alcami,J.; Doutry*,F.; Virelizier,J.L., Lab. d'Immunologie Virale. Institut Pasteur. Paris. *Lab. d'Oncologie Moleculaire. Villejuif, France.

Objective. To ascertain whether p21ras (the product of ras protooncogenes induced during T cell activation and a G protein with known transductionnal properties) can induce signals leading to HIV-LTR transactivation.
Methods. Human cells of two different lineages, fibroblasts (MRC-5) and astrocytes (U373MG astrocytoma cell line) were transiently transfected with vectors permitting the expression of the CAT reporter gene under the control of either the whole LTR of HIV-1 (LAV-1-BRU) or various subcloned fragments of the LTR. A vector permitting the expression of c-Ha-ras coding for a p21 protein with gly-val12 mutation was co-transfected with LTR-CAT vectors.
Results. Co-transfection of c-Ha-ras consistently resulted in a clear (up to 22 fold) transactivation of the whole HIV-LTR. We have performed further co-transfection of an HIV-1 infectious provirus clone (pNL-43) in this system, and shown that transcription of the provirus, including tat-3 protein function induction, was induced by c-Ha-ras transfection. Deletion of the LTR TAR region did not decrease ras induced transactivation. The LTR enhancer was shown to be a main responsive element in this system, since a 96 bp fragment containing the enhancer, or a synthetic oligonucleotide with the exact sequence of the twice repeated NF-KB binding site of the LAV-1-BRU enhancer cloned upstream a TK promoter, were as responsive to ras than the whole LTR.
Conclusion. Our observations are compatible with the hypothesis that endogenous p21 ras, induced during cell activation, participates in HIV-genome transcription through transactivation of the HIV enhancer.

W.C.P.122 CYTOKINE MODULATION OF HIV-REPRODUCTION IN MONOCYTES/MACROPHAGES

Kaunath, Thomas, Zorr, B. and Habermehl,K.-O.
Institute for Clinical and Experimental Virology of the Free University of Berlin, Hindenburgdamm 27, 1000 Berlin 45, FRG.

Objective: Reproduction of different primary HIV-isolates (HIV-1/-2) at a given multiplicity of infection (m.o.i.) in adherent monocytes/macrophages. Modulation of HIV-1 replication in monocytes/macrophages by cytokines and phorbolester.
Results: All HIV-wildtypes (n=49) isolated from patients by cocultivation with peripheral blood lymphocytes (PBL) lead in our investigations to an infection in monocytes/macrophages. There were graduations regarding the productivity.of replication, between low level and productive HIV-infection. The role of interfering defective particle will be discussed. Cytokines effected the HIV-replication in monocytes/macrophages in vitro. Compared to control cells there was a stronger HIV-reproduction with rM-CSF and rGM-CSF especially if the cytokines were applied before HIV-infection. Also rIL-3 enhanced the HIV-replication in a positiv manner. Treatment of monocytes/macrophages with phorbolester (TPA) lead to time-dependent supression or activation of HIV-1 replication.
Conclusion: Low level HIV-replication in monocytes/macrophages can be changed to a more productive HIV-infection by different cytokines. Possible meanings about the in vivo situation will be discussed.

W.C.P.123 HIV-ASSOCIATED CHANGES IN TRANSMMEBRANE SIGNAL TRANSDUCTION IN MACROPHAGES

Sudhir Gupta and Vayuvegula B.
University of California, Irvine, California, USA.

Objective. Macrophages play an important role in the pathogenesis of AIDS. However, the mechanisms of HIV-induced dysfunctions in macrophages are not well understood. We hypothesize that the macrophage dysfunctions in HIV infection are a result of a deficit in transmembrane signal transduction. Furthermore, adhesion molecules expressed on macrophages may play an important role in the transmision of HIV infection to CD4+ T cells as well as in inducing transmembrane signalling. The objective is to examine the changes in plasma membrane potentials and in intracellular free calcium ($[Ca^{++}]_i$) in uninfected macrophages (U937) and HIV-infected (U937/HIV) macrophages.
Methods. Cells were cultured in the presence or absence of monoclonal antibodies against adhesion molecules, lymphocyte-associated antigen -1 and 3 (LFA-1, LFA-3) and intercellular adhesion molecule 1 (ICAM-1). Plasma membrane potentials were measured with DIOC5 dye and $[Ca^{++}]_i$ with Indo-1 dye using FACS.
Results. The membrane potentials of U937 and U937/HIV cells were 120 and 39 mean channe numbers respectively. Anti-LFA-1 and anti-LFA-3 induced hyperpolarization of both U937 and U937/HIV cells. In contrast, anti-ICAM-1 decreased (depolarized) membrane potentials of U937 (120 to 40 mean channel numbers), but increased the membrane potentials of U937/HIV cells (39 to 60 mean channel numbers). The basal $[Ca^{++}]_i$ levels in U937/HIV cells were elevated (105 nM) as compared to U937 cells (90 nM). Anti-LFA-1 induced less increase in $[Ca^{++}]_i$ levels in U937/HIV (120 nM) as compared to U937 cells (180 nM).
Conclusion. This study demonstrates a defect in the transmembrane signal transduction in macrophages infected with HIV, which could be responsible for macrophage dysfunction in AIDS. (Supported by USPHS Grant AI-26456).

W.C.P.124 PREVALENCE AND SIGNIFICANCE OF ANTIBODIES TO NEF (p27) IN HIV-1 INFECTION.

Chiengsong-Popov,Rachanee.;Panagiotidi,C.;Bowcock,S. and Weber,J. Department of Infectious Diseases,Royal Postgraduate Medical School, London W12 ONN, U.K.

Objective. To measure and analyse the humoral immune response to nef (p27) in serial samples from HIV-1 infected subjects.
Methods. Purified recombinant nef protein derived from E.coli (Transgene,Strasbourg) was used as the antigen in a direct, anti-globulin ELISA assay. Specificity of the anti-nef response was confirmed with a large battery of HIV-negative sera, and by immunoblotting on HIV and on nef protein. Sera were obtained from serial bleeds over a six year period from homosexual men and haemophiliac patients, and were further assayed for antibody to HIV env and gag proteins, and for HIV p24 antigen.
Results. Antibodies to nef appear simultaneously with antibodies to HIV structural proteins at sero-conversion in 65% of cases. Only 1/65 sero-converters expressed detectable anti-nef antibodies prior to sero-conversion. This subject had anti-nef present 9 month prior to full sero-conversion. High initial titres of anti-nef antibody after sero-conversion correlated with lack of progression to AIDS.
Conclusion. The expression of the nef protein prior to sero-conversion occurs, but is a rare phenomenon (circa 1%). The titre of anti-nef does correlate with protection from disease in haemophiliacs, suggesting that this negative regulatory protein may slow viral replication in vivo.

W.C.P.125 HUMAN HERPESVIRUS 6 (HHV-6) AS A POTENTIAL COFACTOR IN AIDS

Lusso, Paolo*, Ensoli, B*., Negro, F.**, DeRocco, S.E.***, Markham, P.D.***, Gallo, R.C.*, et al. *NCI, Bethesda, MD, **Georgetown Univ., Rockville, MD, ***Bionetics Research, Inc., Rockville, MD. U.S.A.

Objective: To investigate the interactions between HHV-6 and HIV-1 in vitro and the potential role of HHV-6 in the pathogenesis and/or disease progression in AIDS.
Methods: Human peripheral blood mononuclear cells (PBMC) or enriched adherent cells and established cell lines of T-lymphocytic or monocytic origin were simultaneously infected in vitro with HHV-6 and HIV-1. Electron microscopy, immunohistochemical analyses and dual-probe in situ hybridization were employed to demonstrate dual infection at the single cell level.
Results: HHV-6 and HIV-1 can productively coinfect human CD4+ T lymphocytes of both normal and neoplastic origin, resulting in accelerated viral antigen expression and cellular death. Cells of the mononuclear phagocytic system can also be coinfected by the two viruses. HHV-6 is a potent transactivator of HIV-1. HHV-6-infected cells can be visualized in AIDS patients blood.
Conclusion: These in vitro observations suggest that HHV-6 is a particularly suitable candidate as a cofactor in AIDS. Studies are underway to detect dually infected cells in PBMC from HIV-1-infected individuals.

W.C.P.126 MISE EN EVIDENCE DE SEQUENCES VIRALES HIV CHEZ DES SUJETS MARTINIQUAIS A WESTERN BLOT INDETERMINES

L. D'Auriol*, C. Neisson-Vernant°,
F. Barre-Sinoussi', D.Cales-Quist°, F. Galibert*,
N. Monplaisir°.

*Laboratoire d'hématologie expérimentale, Centre Hayem Hopital St-Louis, °CHRU de Fort-de-France, 'Institut Pasteur de Paris.FRANCE

Objectif. Le taux de séropositivité HIV est élevé en Martinique, intermédiaire entre celui observé en Europe et en Afrique, avec un fort taux de de western blot indéterminés (0,16 %). La transmission y est essentiellement hétérosexuelle (64 %). La PCR a permis de mettre en évidence des séquences virales HIV chez des homosexuels appartenant à des cohortes américaines, jusqu'à 36 mois avant la séroconversion, c'est pourquoi nous avons recherché la présence de séquences virales chez certains sujets contacts séronégatifs ou à western blot indéterminé.
Méthodes. Les amplifications géniques (PCR) ont été réalisées suivant la technique de Saiki et al. avec 3 couples d'oligonucléotides situés dans LTR gat et tat. Les produits d'amplification ont été hybridés en milieu liquide avec des sondes oligo internes marquées au p32 puis migrés sur gel de polyacrylamide.
Résultats. 14 séropositifs ont été testés pour valider la technique. 26 asymptomatiques et 1 Sida à W.B. indéterminé, dont la moyenne de suivi était de 13,5 mois ont été testés. 20 étaient positifs avec les 3 couples, 6 étaient positifs avec l'un des couples et 1 négatif. 8 partenaires séronégatifs de sujets infectés par le virus ont également été testés, 5 d'entre eux étaient positifs.
Conclusion. La PCR a permis de mettre en évidence des séquences virales HIV1 chez un certain nombre de sujets à risque séronégatifs ou présentant un western blot indéterminé. L'utilisation du séquençage sur produits d'amplification permettra la mise en évidence d'éventuelles particularités de ces génomes viraux.

W.C.P.127

HIV ENCEPHALITIS IN ADULTS AND CHILDREN

Rosemay Vazeux, MC Cumont, L Montagnier et al, Institut Pasteur, Paris, France.

Objectives : To study Human Immunodeficiency Virus (HIV) encephalitis in adult and children by identifying the HIV infected cells and determining which additional pathogens are present.
Methods : We have extensively screened frozen CNS tissue of 85 adult and 6 children AIDS patients for the presence of pathogens using a combination of immunohistological staining and in situ hybridization.
Results : A first striking difference between adults and children infected with HIV was the detection of a massive and multifocal HIV encephalitis in 24/85 adult patients, but a failure to detect HIV antigens in 4/6 children who either died with severe and typical AIDS related encephalopathy. 2/6 children with immunologically detectable HIV encephalitis had less severe neurological symptoms. For adults and children, both single and double immunohistological procedures showed that all infected cells had a macrophage/microglial cell phenotype, without any HIV antigen expression in astrocytes, neurons, or endothelial cells. The second striking difference between adult and children encephalopathies was the very frequent association with other CNS pathogens in adult, and their absence in infants with severe encephalopathies.
Conclusion : In adults, dementia is associated with multifocal and diffuse HIV replication, but the presence of severe neurological symptoms in infants without evidence of HIV replication in brain macrophages suggests that persistent, productive viral infection is not required for the pathogenesis of HIV encephalopathy. Opportunistic associated pathogens might play an important role for triggering HIV replication in adult brains.

BLOCKING OF INFECTIVITY AND IMMUNOSUPPRESSION BY AN HIV ENVELOPE-DERIVED SYNTHETIC PEPTIDE

Kieber-Emmons, T.*; Krowka, J.**; Wing, L.*; Whalley, A.*; Berquist, L.* and Morrow, W.J.W.*.
* IDEC Pharmaceuticals Corp., La Jolla, California, ** Department of Laboratory Medicine, University of California School of Medicine, San Francisco, California.

Objective. We have identified an epitope in the external envelope glycoprotein of HIV-1 that is likely to be involved in the binding of this molecule to its cellular receptor, CD4. Independent studies have confirmed the importance of this region in the gp120-CD4 interaction and, in addition, this region may contain an immunodominant T cell epitope.
Methods. An 18 amino acid synthetic peptide was synthesized and purified and its ability to block syncytial formation as well as be recognized by antibodies and T cells from HIV-infected individuals was determined.
Results. The peptide would inhibit 100% of syncytial formation at a concentration of 100 μg/ml. Only 2/18 asymptomatic HIV carriers had detectable levels of anti-peptide antibodies that were significantly different from normal, uninfected control subjects. The peptide did not induce proliferative responses in peripheral mononuclear cells from the HIV-seropositive subjects in either the presence or absence of IL2. Tetanus toxoid and CMV were used as positive controls in these studies. The peptide was shown to suppress recall antigen (CMV and tetanus toxoid) responses, but not PHA-induce proliferation.
Conclusion. The apparent immunosuppressive properties of this peptide indicate a potential pathogenic role of the HIV envelope in the pathogenesis of infection.

W.C.P.129

IMMUNE COFACTORS FOR HIV INFECTION IN MALE HOMOSEXUALS (MHS)

Bentwich, Zvi.H.*; Handzel, Z.T.*; Burstein, R.*; Milchan, R.*; Hahn, T.**; Argov, S.*** et al.
*R. Ben Ari Institute of Clinical Immunology, **Pediatric Research Laboratory, Kaplan Hospital, Rehovot, ***Dept. of Pathology, Soroka Medical Center, Beer Sheba, Israel

Objective. To determine the role of immune cofactors in HIV infection.
Methods. We have studied several immune parameters and functions in a cohort of 1000 male homosexuals (MHS) in Israel, 144 of whom were followed for over 4 years and 18 seroconverted during that period.
Results. Elevated levels of serum acid labile α-Interferon (αIFN), antibodies to nuclear antigens (Histones, SS-A, SS-B and Cardiolipin) antibodies to EBV, CMV and Chlamydia trachomatis, elevated cellular lymphocytotoxicity, with normal serum levels of tumor necrosis factor (TNFα), extremely high inducibility of IFN-γ gene expression upon mitogen stimulation and lower levels of CD4 T cells were all found in a large proportion of HIV seronegative individuals and preceded HIV infection. Further derangements of several of these immune parameters were observed following sero-conversion and at later stages of HIV infection.
Conclusion. Our studies suggest that immune dysregulation is common among MHS, precedes HIV infection and probably accounts for their increased susceptibility to HIV infection and for the development of AIDS.

W.C.P.130

HYPOTHESIS: AIDS IS AN AUTOIMMUNE DISEASE CAUSED BY HIV PLUS ALLOGENEIC CELLS

Hoffmann, Geoffrey W. and Grant, Michael D.
University of British Columbia, Vancouver, Canada V6T IW5

We suggest that the following facts are relevant to AIDS pathogenesis. Firstly, there is complementarity of gp120 and the CD4 protein, and there is also complementarity of CD4 and class II MHC. Hence gp120 can be regarded as MHC-mimicking, and the anti-viral immune response may include an anti-(class II internal image) component. Secondly, immunization with foreign lymphocytes leads to the production of MHC-mimicking (i.e. MHC-image) antibodies. Since infection with HIV usually occurs coincidentally with exposure to allogeneic lymphocytes, infected individuals are likely to make MHC-mimicking antibodies. These facts lead to the idea that AIDS is an autoimmune disease, that is triggered by a combination of HIV and allogeneic cells, rather than by HIV alone. These two stimuli produce MHC-image and anti-(MHC image) immune responses that seem likely to synergize with each other to destabilize the system. We have found anti-collagen antibodies in the sera of many homosexuals, both HIV^- and HIV^+, and in the sera of 16/16 homosexual AIDS patients. These antibodies are also found in alloimmune sera, graft versus host disease and lupus. Our results are consistent with AIDS being an autoimmune disease that is provoked by a combination of allogeneic cells and HIV. The theory leads to further experimentally testable predictions, and ideas concerning possible approaches for prevention of the disease. It suggests that vaccines consisting of gp120, gp160 and anti-CD4 may cause AIDS in individuals belonging to high risk groups.

W.C.P.131

QUANTITATION AND MODULATION OF HIV P24 ANTIGEN CONTENT IN INTESTINAL MUCOSA.

Reka, Sahil; Borrich, A; Kotler, DP
St. Luke's-Roosevelt Hospital Center and Columbia University, New York, NY, USA

Objective: To quantitate HIV expression in the intestine and to determine if viral protein production can be modulated in vitro.
Methods. Mucosal biopsies were assayed directly, or incubated in vitro. HIV content in homogenates was determined by p24 antigen capture ELISA (Coulter). In vitro incubations were performed in media containing varying amounts of hydrocortisone (5-500ug/ml) or prostaglandin E2 (0-50uM).
Results. HIV p24 was found in 44/85 serum specimens, 18/34 biopsies from jejunum, 2/4 from ileum, 9/15 from right colon, 6/10 from left colon, and 70/104 from rectum. In several cases, p24 was detected in tissue but not in serum. When calculated by sample weight, tissue p24 was more than 100 times higher than serum concentrations. As compared to control medium (5ug/ml cortisol), either 50 ug/ml and 500 ug/ml cortisol significantly depressed p24 content after 48 hours in tissue and medium in both AIDS and ARC. In contrast, 5uM PGE2 increased p24 content.

Cortisol (N=10)			PGE2 (N=7)			
5ug/ml	50ug/ml	500ug/ml	0uM	5uM	10uM	50uM
890±233	401±98*	495±92**	570±379	947±519*	308±108	252±127

*p<0.05, **p<0.02; Mean±SEM of p24 pg/mg protein

Conclusions. HIV p24 expression occurs throughout the GI tract. P24 content is higher in tissue than serum, implying intracellular localization in the gut. Mucosal HIV production can be modulated in vitro.

W.C.P.132

CREATION OF A NEW TARGET CELL TYPE FOR HIV-1

Potash, Mary Jane; Volsky, D.J.; St Lukes/Roosevelt Hosp Ctr
Columbia University; New York, NY 10019 USA.

Objective: To investigate the dichotomy between productive and nonproductive HIV-1 infection by construction of a hybrid target cell type between T cell and glial cell lines, and by analysis of its susceptibility to HIV-1.

Methods: A ouabain resistant, HAT sensitive clone of the lymphoblastic T cell leukemia line, CEM, was selected and fused to U251MG, a ouabain sensitive, HAT resistant astroglial cell line with polyethylene glycol. Fusion products were selected in HAT-ouabain, which kills the parental cells.

Results: BEN, a hybrid derived from this fusion, was selected for further analysis. Like U251MG, BEN has glial morphology, growing as an adherent cell with cytoplasmic processes. Like CEM, and unlike U251MG, it displays high amounts of surface membrane CD4. Upon infection with a cytopathic molecular clone of HIV-1, HIV-N1T-A, CEM expresses HIV-1 antigens 5 days after infection, and is killed within 10 days; U251MG expresses approximately 100 fold less HIV-1 than CEM as measured by p24 antigen expression, and is resistant to killing by HIV-1. BEN on infection with HIV-N1T-A displays no cytopathic effects and 100 fold less HIV-1 antigens than CEM.

Conclusions: HIV-N1T-A's cytopathicity for target cells can be dissociated from their high CD4 display. In this case, factors either i) contributed by the glial parent or ii) contributed by the T cell parent and suppressed by the glial parent determine BEN's response to HIV-1 infection.

W.C.P.133 HIV DNA IS PRESENT IN A HIGH PERCENTAGE OF PERIPHERAL BLOOD MONONUCLEAR CELLS IN INFECTED INDIVIDUALS

Hsia, Karen; LeBlanc, E. and Spector, S.A.
University of California San Diego Medical Center, San Diego, California USA

Objective. To determine the percentage of peripheral blood mononuclear cells (PBMCs) containing HIV DNA in infected individuals.
Methods. PBMCs isolated by Ficoll-Hypaque gradient centrifugation were counted by hemacytometer. Crude cell lysates of 10^4, 10^3, 10^2 and 10^1 PBMCs were subjected to polymerase chain reaction (PCR) for 35 cycles in the presence of primers SK38 and SK39 obtained from the Cetus Corp. The specific HIV sequence amplified from these lysates were subsequently analyzed by slot blot and Southern blot hybridizations with a specific HIV oligomer probe (SK19) (Cetus Corp.)
Results. Using 10% of PCR mixtures from 10^4 PBMCs, specific HIV sequences were detected in 7/9 of patients with AIDS; 5/6 patients with ARC; 6/8 asymptomatic HIV seropositive individuals; and 0/4 of HIV seronegative controls. In some of these PCR positive persons, amplified DNA could be detected in 10% of PCR mixtures with only 10 PBMCs, indicating that greater than 10% of PBMC population contained HIV DNA in these infected individuals.
Conclusion. Using in vitro amplification of HIV DNA by PCR, we have detected a very high percentage (greater than 10%) of PBMC containing HIV sequence in seropositive individuals. This reflects a substantially higher percentage of PBMCs actually infected with HIV than previously reported by using in situ hybridization (10^{-4}-10^{-3}).
These findings may be important in explaining the severe immunologic defects associated with HIV infection.

W.C.P.134 PLASMA-ASSOCIATED HUMAN IMMUNODEFICIENCY VIRUS TYPE-1 (HIV) IS A MARKER OF PROGRESSION OF HIV INFECTION.

Robert W. Coombs, A. Collier, K. Chaloupka, L. Corey.
University of Washington, Seattle, WA, USA.

Objective. To assess the duration and time course of HIV plasma viremia and whether the development of plasma viremia correlates with progression of disease.
Methods. We sequentially cultured cell-free plasma for HIV from a cohort of CDC class II, III, IVa and IVc patients. Three ml of plasma was removed, passed through a 0.45 micron filter to remove cells, and 2 ml was then added to 10^7 3-4 day old PHA-stimulated donor peripheral blood mononuclear cells (PBMC) and cultured by a standard mixed-lymphocyte procedure.
Results. All 67 sequentially sampled patients had HIV isolated from their initial and all subsequent PBMC specimens. Twenty-five CDC class IVc (AIDS) patients had plasma samples taken at a mean interval of 6 weeks (range 2-12 wk). Plasma viremia was detected in 21 at their first sampling and 21 had HIV re-isolated from the plasma on subsequent sampling. Of the 4 in whom HIV was not initially detected in plasma, 3 had HIV isolated from plasma on a second sampling. Fourteen patients in CDC class II and III (asymptomatic) and 28 in CDC class IVa (ARC) were sequentially sampled at a mean interval of 6 months (range 1-20 months); 14 (74%) of the initially plasma viremic patients remained persistently positive on resampling. Three of 12 CDC class II-III versus 14/15 CDC IV who were initially plasma HIV negative developed plasma viremia over follow-up ($p<0.001$). Three of 4 CDC class II-III patients with plasma viremia progressed to more symptomatic clinical disease versus 0/8 without plasma viremia ($p=0.034$). The CD4-cell count decreased significantly for 8 patients that progressed to plasma viremia (Wilcoxin signed rank $p=0.006$) as compared to 7 that remained viremic ($p=0.088$) and 7 that remained nonviremic ($p=0.118$).
Conclusion. Previous cross-sectional studies indicated that the frequency of plasma viremia increased with stage of infection; these data indicate that the frequency of plasma viremia progresses over time, that once it develops it persists and is associated with a decrease in CD4-cell count.

W.C.P.135 BLOCKING OF ANTIBODY-ENHANCED HIV-1 INFECTION BY RECOMBINANT SOLUBLE CD4(rCD4).

Zeira, Michael, Byrn, R.A. and Groopman, J.E.
New England Deaconess Hosp.,Harvard Medical School, Boston,MA U.S.A.

Objective: To test whether rCD4 can block antibody-enhanced HIV-1 infection of Fc-receptor (FcR) expressing cells.
Methods: The monocytic cell line, U937 served as a target for HIV-1 IIIB strain infection. FcR and CD4 expression were measured by flow cytometry. Virus neutralization tests were performed by mixing dilutions of heat inactivated patient serum with 100TCID$_{50}$ of HIV-1. After incubation for 1 hr.at 4°C, U937 cells were added and infection was monitored by reverse transcriptase activity. High concentrations of patient serum neutralized HIV-1 but a subneutralizing concentration from the same patient enhanced infection. The role of CD4 in this antibody-enhanced infection was tested using rCD4.
Results: Flow cytometry of U937 cells showed that 74% express FcrRII and 97% express CD4. At subneutralizing concentrations (10^{-4}-10^{-6} dilutions) 5 out of 8 patient sera enhanced viral infection. The enhancement index was 1.2 to 2.18 in comparison with HIV-1 Ab-negative sera. This enhancement of HIV-1 infection was totally blocked by 1µg/ml rCD4.
Conclusion: Some HIV-1 Ab-positive human sera can neutralize HIV-1 and at higher dilutions enhance infection. Because rCD4 can block this enhancement, this FcR dependent infection pathway is also CD4 dependent.

W.C.P.136 HIV-2 SEROCONVERSION IN SENEGAL, WEST AFRICA

Maayan, Shlomo*; Kanki, P*; M'Boup S**; Marlink, R*; Travers, K*, Essex, M* et. al. *Harvard School of Public Health, Boston, MA, USA, ** University of Dakar, Dakar, SENEGAL.

Objective. HIV-2 has been found at high rates in populations of West Africa where as yet high rates of AIDS cases have not been described. This has suggested that HIV-2 may differ in pathogenicity from HIV-1. In order to evaluate this on a population level the rate of transmission of the virus is important to determine. Through evaluation of sequential samples from a high risk group in Dakar, Senegal, we determined and characterized seroconversion in this population.
Methods. A population of 1300 registered female prostitutes have been followed with sequential serology since 1985. All serum samples were evaluated for antibodies to HIV-1 and HIV-2 by immunoblot
Results. 14 women were found to seroconvert to HIV-2 with 22.6 person-years of observation. The mean time of observation prior to seroconversion was 17 months. At the time of seroconversion antibodies to the env gene products gp38-40 and gp105 for HIV-2(MS) were readily detected by immunoblot. 14/14 had antibodies to p24(gag), 13/14 to p66(pol), 11/14 to p51(pol), and 8/14 to p15(gag). HIV-2 seroconverters were compared to 1106 women (963 person-years) who remained seronegative. Risk factor analysis showed that seroconverters were significantly older than non-seroconverters ($p<.025$). Nationality or years of prostitution were not significant risk factors for seroconversion. None of the seroconverters developed AIDS or related signs. The seroconversion rate was found to be less than 2% per year based on person-years of observation in this large high risk population.
Conclusion Seroconversion for HIV-2 appears quite low despite over 10% prevalence in this high risk population. This suggests slow spread of HIV-2 in contrast to HIV-1. The stability of this virus infection in the absence of AIDS further indicates important biological differences between HIV-2 and HIV-1.

W.C.P.137 STRESS MEDIATED INDUCTION OF HIV EXPRESSION FROM A CHRONICALLY INFECTED PROMONOCYTIC CELL LINE.

Stanley, Sharilyn, Folks, T.M., Fauci, A.S. LIR, NIAID, NIH, Bethesda, MD U.S.A.

Objective. To investigate the ability of various cell stressors to induce expression of HIV from a state of latent or chronic infection.
Methods. A chronically HIV infected low-virus producing promonocytic cell line (U1) derived from infection of U937 cells was exposed to varying doses of UV-C, UV-B, or UV-A. Virus induction was measured by appearance of reverse transcriptase (RT) activity in culture supernatants as well as by an increase in percent of positive cells on indirect immunofluorescence (IFA) staining for HIV proteins. In separate experiments U1 cells were exposed to heat shock (41.3°C for 1-5 hours) and followed for appearance of RT activity over several days.
Results. A 2-3 fold induction of RT activity over untreated cells was seen at 3-5 days after UV-C and UV-B stimulation. Peak induction was seen over a narrow dose range of 0.75-1.0 mJ/cm2 for UV-C and 7-9 mJ/cm2 for UV-B. UV-A, which does not usually cause DNA damage, did not induce HIV expression in this cell line. IFA experiments also revealed a time dependent increase in percent positive cells after UV-C exposure. Decreased cell viability and a temporary growth arrest (suggesting cell stress) were associated with UV doses which induced HIV. Cells exposed to heat shock also showed an increase in RT activity over controls without decreased viability.
Conclusion. Chronically infected U1 cells can be induced to express HIV by UV irradiation in wavelengths that cause cell stress and by heat shock.

W.C.P.138 ANTI-HISTONE H2B ANTIBODIES IN HIV-SEROPOSITIVE INDIVIDUALS

Morrow, W.J.W.*; Whalley, A.S.*; Leahy, C.*; Rosenberg, J.*; Stricker, R.B.** and McCutchan, J.A.***.
* IDEC Pharmaceuticals Corp., La Jolla, California, ** Department of Laboratory Medicine, University of California School of Medicine, San Francisco, California, *** Division of Infectious Disease, University of California Medical Center, San Diego, California. U.S.A.

Objective. The purpose of this study was to quantitatively measure the levels of anti-H2B antibodies in HIV-seropositive individuals to assess whether the prevalence and levels of antibody correlated with disease status.
Methods. Previous studies carried out in our laboratories have demonstrated the presence of anti-lymphocyte antibodies in individuals with AIDS and at risk for AIDS. These antibodies are specific for an 18 kd antigen present on activated or HIV-infected CD4$^+$ T cells. Further studies on the 18 kd antigen have revealed that it is biochemically similar to, and immunologically cross-reactive with, histone H2B.
Results. The prevalence of anti-H2B antibodies in serum specimens tested was as follows: AIDS, 13/38 (34%); ARC, 19/31 (61%); lymphadenopathy syndrome, 41/132 (31%); HIV-seropositive asymptomatic, 3/19 (16%); HIV-seronegative normal controls, 4/50 (8%). The normal range was established as the mean + 2 SD of 50 samples in the normal control group. There was only a weak correlation ($r = 0.42$, $p = 0.001$) between serum immunoglobulin levels and titers of anti-H2B antibodies.
Conclusion. Although the prevalence of anti-H2B antibodies was associated with progression of disease, there was no clear relationship between these antibodies and the numbers of circulating CD4 cells.

W.C.P.139 MISE EN EVIDENCE DE SEQUENCES VIRALES HTLV1 CHEZ DES MALADES NEUROLOGIQUES SERONEGATIFS A W.B. INDETERMINES.

N. Néeplaisir*, L. d'Auriol°, M. Ouka*, F. Galibert°, G.Buisson*, J.C. Vernant*.

° Laboratoire d'hématologie expérimentale - Centre Hayem Hopital Saint-Louis.
* CHRU de Fort-de-France., Martinique

Objectif. L'augmentation significative de la séroprévalence dans certains groupes de populations ainsi que l'existence de malades séronégatifs présentant des tableaux cliniques de HAP (HTLV1 associated paraplegia), suggèrent que le virus HTLV1 pourrait être présent chez un certain nombre de sujets séronégatifs. C'est pourquoi nous avons utilisé la PCR pour rechercher chez des sujets séronégatifs à risque ou symptomatiques des séquences virales HTLV1.

Méthodes. Les amplifications géniques (PCR) ont été réalisées suivant la technique de Saiki avec 2 couples d'oligonucléotides, situés respectivement dans gag et tax. Les produits d'amplification ont été hybridés avec des sondes internes marquées au p^{32}, puis migrés sur gel de polyacrylamide.

Résultats. L'étude de 24 sujets HTLV1 séropositifs a permis la validation de la technique utilisée. 14 malades séronégatifs ayant une symptomatologie neurologique ont été étudiés : 9 "HAP-Like" dont 4 étaient positifs avec les 2 couples d'oligo, 2 positifs avec les oligo gag seulement, 2 positifs avec les oligo tat seuls, 1 négatif avec les 2. 3 sujets dont les diagnostics suivants avaient été portés : 1 neurofibromatose, 1 cryptococcose, 1 sclérose latérale amyotrophique étaient positifs. 2 prélèvements de malades neurologiques "contrôles" : Moya-Moya, séquelle d'accident vasculaire cérébral étaient négatifs. 2 enfants de HAP séronégatifs et 9 sujets positifs en Elisa, négatifs ou indéterminés en western blot, étaient positifs en PCR.

Conclusion. La PCR a permis la détection d'informations génétiques HTLV1 chez certains sujets symptomatiques séronégatifs ou présentant des western blot ininterprétables. Une enquête épidémiologique par PCR nous permettra de vérifier l'hypothèse d'un taux d'infection de base dans la population, supérieur à celui détecté par l'intermédiaire de la sérologie.

W.C.P.140 LYMPHOCYTE SUBPOPULATIONS IN MEDITERRANEAN KAPOSI'S SARCOMA

Hatzakis,Angelos*;Georgopoulou,O.*;Ferentinou, D.*;Polychronaki,H.*;Vassilopoulou-Kada,H.*;Stratigos,J.*;Kaloterakis,A.*;Trichopoulos,D.*;Mueller,N.**;Biggar,R.***.
*Athens Univ. Medical School, Athens, Greece, **Harvard School of Public Health, Boston, USA, ***National Cancer Institute, Bethesda,USA.

Objective. To evaluate the lymphocyte subpopulations in Mediterranean Kaposi's sarcoma (MDKS) which is a form of classic Kaposi's sarcoma prevalent in Greece and is characterized by frequent gastrointestinal tract lesions at the time of diagnosis.
Methods. 19 histologically confirmed cases (12 males, 7 females) of MDKS aged 48-80 years and 28 controls of similar age and sex enrolled in the study. The controls were patients admitted in opthalmology and orthopedic clinics. All patients and controls were HIV(-).
Results and Conclusions.

	Mean values						
	CD4		CD8		CD4/CD8	CD16	
	/mm3	%	/mm3	%		/mm3	%
MDKS	833	35.6	680	28.8	1.3	432	18.3
Controls	1141	40.4	769	26.5	1.7	511	18.8
P-value	<0.01	<0.01	n.s.	n.s.	<0.05	n.s.	n.s.

The moderately supressed levels of CD4 lymphocytes in MDKS may, partly, explain the clinical manifestations. The etiological implication of this finding is not clear.

W.C.P.141 EXPERIMENTAL INFECTION OF CYNOMOLGUS MONKEYS WITH HIV-2

Putkonen, Per; Böttiger, B.; Warstedt, K.; Thorstensson, R.; Albert, J. and Biberfeld, G. National Bacteriological Laboratory, Stockholm, Sweden.

Objective. To induce experimental infection of cyncmolgus monkeys with HIV-2.
Methods. 4 cynomolgus monkeys (Macaca fascicularis) were inoculated intravenously with HIV-$2_{SBL-K135}$ which had been grown mainly in fresh human and monkey lymphocyte cultures and another 6 monkeys were inoculated with HIV-$2_{SBL-6669}$ which had been propagated for a long time in continuous human cell lines.
Results. Virus could be isolated from 3 of the SBL-K135 infected monkeys but from none of the SBL-6669 infected monkeys. All animals seroconverted although the antibody response was lower in SBL-6669 infected monkeys. Varying degrees of lymphadenopathy were observed but there were no significant changes in the numbers of CD4+ and CD8+ T cells. The infection was transferred with blood from a SBL-K135 infected monkey to 2 previously uninfected monkeys. 4 animals inoculated with HIV-$2_{SBL-K135}$, which had never been propagated in continuous human cell lines showed strong antibody responses against both gag- and env-encoded proteins of HIV-2. None of the SBL-6669 infected monkeys showed antibodies to gag proteins.
Conclusion. Infection of cynomolgus monkeys with HIV-$2_{SBL-K135}$ represents a useful experimental model for HIV vaccine trials.

W.C.P.142 EFFECT OF WHOLE BODY HYPERTHERMIA ON CATS INFECTED WITH FELINE LEUKEMIA VIRUS

Macy, Dennis W.;* Gasper, PW;** Oulton, SA;** Zeidner, NS;** Gillette, EL;*** Scott, RJ;*** McGee ML***. Department of Clinical Sciences*, Department of Pathology**, Department of Radiology and Radiation Biology***, Colorado State University, U.S.A.

Fever indicates that a complex interaction of cells and cytokines has been activated. Whole body hyperthermia therapy mimics the natural process of fever and it triggers the elaboration of interleukins and interferons which may be beneficial to animals infected with retroviruses.
We tested the effect of whole body hyperthermia (WBH) on six specific pathogen-free cats persistently infected with a minimally pathogenic strain of feline leukemia virus (FeLV-1661E). The cats were experimentally infected two years prior to this study. Cats were anesthetized and were heated to a temperature of 42°C for two hours using a radiant heat device (Enthermics, Menomonee Falls, Wisconsin). Rectal and subcutaneous ventral abdominal temperature probes were used to monitor each patient's body temperature. Computer control and monitoring assured uniform WBH.
Serum and plasma samples were obtained prior to heating, at plateau heat, 2 hours after reaching plateau and 24 hours after heating.
None of the cats became FeLV negative. We observed a significant increase in plasma interferon activity which returned to pretreatment levels 24 hours post-therapy.
A simultaneous decrease in the FeLV reverse transcriptase activity was observed 2 hours after reaching plateau temperature. Reverse transcriptase activity returned to pretreatment levels 24 hours post-therapy.
While WBH did not alter the infection status of 6 FeLV positive cats, our work demonstrates that cats can tolerate WBH and suggests that WBH may have its place in multimodality treatment of retrovirus infections.

W.C.P.143 EXPERIMENTAL INFECTION OF SPECIFIC PATHOGEN FREE (SPF) CATS WITH U.K. ISOLATES OF FELINE IMMUNODEFICIENCY VIRUS (FIV)

Hopper, Chadda ; Harbour, D. and Gruffydd-Jones, T.
University of Bristol, Bristol, U.K.

Objective. To determine the course of experimental infection of cats with FIV using 3 different isolates.
Methods. Three groups (1,2 and 3) of SPF female cats, consisting of 4, 5 and 5 cats respectively, were inoculated intravenously with FIV, each group with a different isolate. Twelve cats were given cell-free virus and 2 from group1 were given infected lymphocytes. Group1 cats were 12 weeks old when inoculated; Groups2 and 3 each comprised 2 young adult cats with one 20 week and two 12 week old kittens.
An uninfected adult male SPF cat was housed with each group. In group1 the tom was not introduced until 36 weeks post-inoculation (p.i.). The temperature and clinical signs of all cats were monitored daily and routine biochemistry and haematology were performed weekly. Virus isolation was performed every 2-4 weeks immediately p.i., then every 2 months. FIV antibody development was monitored in all groups and lymphocyte transformation assays were done weekly for groups 2 and 3. Group1 had been studied for 74 weeks p.i., groups 2 and 3 for 12 weeks p.i.
Results. All inoculated cats seroconverted by 6 weeks p.i.and FIV was recovered from all cats (by 3 weeks p.i. in all but one). Lymphocyte transformation assays showed marked changes over the period studied but the uninfected males showed similar changes. Persistent generalised lymphadenopathy occurred in 13/14 infected cats from 6 weeks p.i. onwards. Two cats in group1 became pyrexic 7 weeks p.i. with accompanying weight loss, lymphopenia and bacterial cellulitis. One recovered after antibiotic therapy, the other was destroyed. Cats in this group developed a number of minor problems such as cystitis, vaginal discharge and diarrhoea, which resolved with or without treatment, and 2 cats had intermittent reduction in the polymorph to lymphocyte ratio. An adult female in group 2 developed marked pyrexia 5 weeks p.i. and aborted 4 foetuses. The ensuing weight-loss, diarrhoea, anaemia, jaundice and profound leucopenia necessitated euthanasia. The male cats showed no significant clinical signs and have neither seroconverted nor become infected to date.
Conclusion. Significant clinical and laboratory findings were present from 6 weeks p.i. onwards in cats experimentally infected with FIV.

W.C.P.144 A MOUSE MODEL FOR INVESTIGATING HIV-1 REPLICATION

Graham, Barney and Wetherall, N. Vanderbilt University School of Medicine, Nashville, TN, USA.

Objective. There is great need for a small animal model of HIV-1 infection. We have developed a system in mice to evaluate the effects of chemotherapy and passive antibody on HIV-1 replication.
Methods. An immunomodulation regimen was devised to allow the growth of human CD4+ cell lines CEM (lymphocytic) and U937 (monocytic) in BALB/c mice. Female, pathogen free, retired breeders underwent sublethal irradiation and depletion of L3T4+ lymphocytes utilizing the monoclonal antibody GK1.5. Mice were then inoculated with 2 X 10^7 CEM cells or U937 cells subcutaneously.
Results. By day 8 a subcutaneous plaque could be felt and by day 14 visible tumors were present. Both cell lines formed tumors that grew exponentially. If maintenance GK1.5 was administered tumor growth continued, but without maintenance tumor growth plateaued during week 3 and then regressed. Subcutaneous tumors were infected by inoculation with CEM cells chronically infected with HTLV-IIIB which resulted in HIV-1 antigenaemia in mice with both CEM and U937 tumors. Mice remained active and appeared healthy throughout the experiment.
Conclusions. When standardized this system should provide an inexpensive approach to assess anti-HIV therapeutic and prophylactic agents in vivo. The approach could also be adapted to other viral systems in which small animal models are unavailable, and has potential application in many other fields of biomedical investigation.

This work is supported by the U.S. Army Medical Research and Development Command under contract No. DAMD17-88-C-8071.

W.C.P.145 ANALYSIS OF GUINEA PIG DERMAL HYPERSENSITIVITY TO HIV WHOLE VIRUS IMMUNOGEN

Archer, Michael*; and Sheppard, H.**. *Viral and Rickettsial Disease Laboratory, Department of Health Services, Berkeley, CA, USA, **California Public Health Foundation, Berkeley, CA, USA.

Objective. To determine the type of reactions to anticipate in humans, particularly immediate or allergic type, experiments were performed in guinea pigs on the ability of an HIV whole virus immunogen to induce and elicit skin reactivity.
Methods. Purified HIV, inactivated with gamma-irradiation and beta-propiolactone, has been prepared for use in boosting immune responses in infected individuals (provided by Dr. Jonas Salk, Salk Institute, CA, USA). It is used in man combined with incomplete Freund's adjuvant (IFA) intramuscularly or in saline as an intradermal injection. Animals received immunogen in IFA and were skin tested 10 weeks later with graded doses of immunogen in saline along with unimmunized controls. Animals were retested one week later to assess the booster effects of intradermal injections. Reactions were scored for intensity and diameter of erythema immediately, at 20 minutes, and at 4, 24, 48, and 72 hours. The change in skin thickness was assessed by a caliper.
Results. No immediate, 20 minute dermal, or systemic reactions have been observed. In animals receiving immunogen in IFA, reactions peaked at 24 hours with a loss of induration by 48 hours, consistent with a Jones-Mote form of sensitivity. Animals immunized with immunogen in saline evidenced more prolonged reactions with induration at 48 hours. Control animals, showed reactions at the second skin test equivalent to immunized animals.
Conclusion. HIV immunogen elicits DTH reactions in guinea pigs, the reactions resemble those seen with common proteins, and immediate hypersensitivity is not seen under the conditions of these experiments. These studies provide useful information on the safety and proper formulation of the immunogen for use in man.

W.C.P.146 GROWTH CHARACTERISTICS OF SIMIAN KAPOSI'S SARCOMA IN NUDE MICE.

Tsai, Cheng*, Tsai, C.**, Woon, M.*, Sligh, J.M.*
*St. Louis University, St. Louis, Missouri, USA, and **Washington Regional Primate Research Center, Seattle, Washington, USA

Objective. To establish a nude mouse model for simian Kaposi's sarcoma (KS) associated with SRV-2 infection.
Methods. Five to ten million cells of simian KS-like cell line from SAIDS associated with SRV-2 infection (kept greater than one year and 16 passages) were injected subcutaneously in 12 athymic albino nude mice. Normal monkey or human fibroblasts were used as controls. Routine histology and tissue culture were carried out with xenografted lesions and tumor.
Results. Xenograft produced nodular growth within 3-6 days, however, spontaneous regression occured in 12 mice except one in which a large tumor developed after 16 weeks. The lesions showed spindle fibrovascular proliferations involving dermis, subcutis, and lymph nodes similar to KS. The histomorphology of the single tumor ranged from pleomorphic anaplastic sarcoma to areas of spindle cell tumor with slits and extravasation of red blood cells, erythrophagocytosis by tumor cells and lymphoplasmacytic infiltration. Multiple hemorrhagic pulmonary lesions similar to KS were found in this mouse. Culture of this tumor revealed identical cells in growth, morphology, cell markers and DNA cell cycle as the original cultured cells. SRV-2 was isolated from the grafted tumor as well as from the original tumor and cultured cells.
Conclusion. Spectrum of KS-like lesions can be produced in nude mice by injection of cultured simian KS cells for use as a model system for KS.

W.C.P.147 DEVELOPMENT OF A STUDY SET ON THE PATHOLOGY OF SIMIAN RETROVIRAL DISEASES.

Ribas, Jorge L.* **; Baskin, G.***; King, N. W.****; McClure, H. M.*****; Lowenstine, L. J.******; Axthelm, M. L.*******; et al.
*Walter Reed Army Institute of Research and **Armed Forces Institute of Pathology, Washington, D.C., ***Delta Regional Primate Research Center (RPRC), Covington, LA, ****New England RPRC, Southborough, MA, *****Yerkes RPRC, Atlanta, GA, ******California RPRC, Davis, CA, and *******Oregon RPRC, Beaverton, OR, U.S.A.

Objective. To develop a study set on the pathology of retroviral infections in nonhuman primates. The set includes microscopic slides, color transparencies and a syllabus in English.
Methods. Simian Type D retroviruses and lentiviruses are etiological agents of acquired immunodeficiencies in susceptible macaque monkeys. Lesions in multiple organs from experimentally infected monkeys have been photographed and prepared into histologic sections.
Results. Approximately 35 of the most common lesions, including opportunistic infections and malignancies, are represented in the approximately 50 microscopic slides. Gross and microscopic color photographs and a syllabus provide supplemental learning material.
Conclusion. The study set should be available for worldwide distribution through the interlibrary loan network at the end of 1989. It is designed for biomedical scientists interested in the pathology of simian retroviral diseases and in simian models for human retroviral diseases.

W.C.P.148 BIOMEDICAL ENGINEERING APPROACH, THEORY AND SUBSTANTIATION OF THREE LEVEL AIDS THERAPY: ANTI-HIV LASER TRAPS, PREVENTIVE AIDS CAPNOTHERAPY AND CURATIVE COMPUTED CT-MRI TOMOGRAPHY

Vasilionkaitis, Victor.
Lithuanian Cancer Research Institute, Vilnius, Lithuania, USSR.

After biomechanical and computed modelling of HIV spreading a three level AIDS therapy or prevention procedures in only infected by HIV proposed. First level of anti-HIV therapy include laser traps from 1 to 10 classes depending selectivity for circulating pathologic agents (infectious, malignant, leukemic) with curative screen installed with blood or lymph seperators for external contact therapy at thin layers and return to natural flow. Laser trap permit remotes photodynamic procedures (killing, sterilization, stimulation) with indicators (HpD). Second level-regional tissue, blood, lymph remote sterilization by decrease local pH till virusocidal effect after safely instant soluble gas (CO_2) intravascular, in bone marrow, intralymphatic use. AIDS gas therapy (capnotherapy) permit curatives procedures against infectious agents of all types, malignant, leukemic cells in turn step by step at all regions. Simultaneous elimination of gas remedy surplus (CO_2) by expiration of patients or surface heparinized extracorporeal artificial lung used. Third level of therapy include novel curatives CT-MRI devices with correcting tracers for orientation in scanning layers by CT-microscalpel or targeting drugs for CT-ultramicrosurgery, selective regulating drugs delivery including brain for correction of immune status.

W.C.P.149

W.C.P.150

Th.C.P.1 ROLE OF N-LINKED GLYCANS IN THE INTERACTION BETWEEN THE ENVELOPE GLYCOPROTEIN OF HIV AND ITS CD4 CELLULAR RECEPTOR. STRUCTURAL ENZYMATIC ANALYSIS.

E. Fenouillet**, B. Clerget-Raslain*, J.C. Gluckman*, D. Guétard**, L. Montagnier** and E. Bahraoui**
* Laboratoire de Biologie et Génétique des Déficits Immunitaires, Hôpital de la Pitié-Salpêtrière, Paris, France. ; ** Unité d'Oncologie Virale, Institut Pasteur, Paris, France.

gp120 and CD4 are two glycoproteins that are considered to interact together to allow the binding of HIV to CD4+ cells. We have utilized enzymatic digestion by endoglycosidases in order to analyze N-linked carbohydrates chains of these proteins and their possible role in the interaction of gp120 or gp160 with CD4. SDS denaturation was not necessary to obtain optimal deglycosylation of either molecule, but deglycosylation of CD4 nonetheless depended on the presence of 1% Triton x 100 . Endo H and Endo F that cleave high mannose type and biantennary glycans diminish the MW of the glycoproteins from 120 or 160 Kd to 90 or 130 Kd respectively, but these enzymes had no action on CD4 glycans. Endo F N-glycanase mixture, which acts on all glycan species including triantennary chains led to complete deglycosylation of gp120/160 and of CD_4. Therefore, probably half of the glycan moieties of gp 120/160 are composed of high mannose and biantennary chains, the other half being triantennary species. The carbohydrates structures of CD4 seems to be triantennary chains. To analyze the binding of gp120/160 to CD4, we used a molecular assay in which a monoclonal antibody (110-4) coupled to Sepharose CL4B allowed the attachment of soluble gp120/160 to the beads ; ^{125}I-sCD4 was then added to measure the binding of CD4 to different amounts of gp120/160. Binding to gp160 was not modified when using completely deglycosylated ^{125}I-sCD4 , while deglycosylation of gp120 or of gp160 resulted in the decrease of the binding to native CD4 by 2 and 5 fold respectively. Native and deglycosylated gp120/160 bound to CD4+ cells with comparable affinities. In addition, deglycosylated gp120 displaced ^{125}I-gp160 binding to CD4+ cells and inhibited fusion of fresh Molt-T4 cells with CEM HIV1- or HIV2-infected cells to the same extent. Taken together, these results indicate that carbohydrates of CD4 and of gp120/160 do not play a significant role in the in vitro interaction between these two molecules.

Th.C.P.2 HIGH LEVEL EXPRESSION OF NATIVE REVERSE TRANSCRIPTASE AND MUTANTS AFFECTING THE ENZYME ACTIVITY

Soutschek, Erwin*; Motz, M.*; Wagner, R.*; Wolf, H.*
*Max von Pettenkofer Institute, Ludwig Maximilian University, München, FRG

Objective. High level expression of reverse transcriptase of HIV 1 in E.coli for crystallographic studies.
Methods. The expression of the native enzyme in E.coli was achieved by the use of synthetic oligonucleotides. The recombinant products were detected by Western blot analysis. The activity was determined by a standard reverse transcriptase assay.
Results. By partially adopting the E.coli codon usage a high and stably expressed, active reverse transcriptase was obtained. Minor changes in the aminoterminal amino acid sequence resulted in a complete loss of enzyme activity, which could be due to conformational changes inhibiting dimer formation. Additional amino acids at the aminoterminus resulted in increased accessibility to bacterial protease(s). The estimated molecular weights of the degradation products are 51 kD, 41 kD and 29 kD. A defined degradation pattern as judged by western blot analysis indicates the involvement of cellular derived proteases in the final processing of the pol polypeptide.
Conclusion. An active reverse transcriptase could be purified from E.coli lysates for structural determination. Mutant expression products indicate the involvement of cellular proteases in the pol polypeptide processing.

Th.C.P.3 HTLV-I BINDS NOT ONLY TO HUMAN T LYMPHOCYTES, BUT ALSO TO B CELLS AND MONOCYTES.

Subhash Dhawan, Paolo Casali, Howard Z. Streicher, Larry M. Wahl and Abner L. Notkins, National Institute of Dental Research and National Cancer Institute, NIH, Bethesda, Maryland 20892, U.S.A.

Objective: To ascertain whether blood mononuclear cells other than T lymphocytes serve as targets for HTLV-I infection.
Methods: Purified HTLV-I was biotinylated using the procedure we developed for the labeling of Epstein-Barr virus (1). To positively identify virus binding cells, biotinylated HTLV-I was used in conjunction with FITC-conjugated monoclonal antibodies probes specific for different mononuclear cell subsets in dual color fluorescence flow cytometry. Cell-bound virus was detected using PE-conjugated avidin.
Results: Dual color contougrams obtained by fluorescence flow cytometry analysis of human peripheral blood mononuclear cells reacted with biotinylated HTLV-I bound to T lymphocytes (both CD4+ and CD8+ cells), B cells and monocytes. The bindings was efficient and dose-dependent. It could be inhibited by cold virus particles. Moreover, binding of biotinylated HTLV-I to human monocytes was prevented by the specific IgG from a HTLV-I+ patient with ATL. In conclusion, we showed that: (a) biotinylation does not affect the functional property of HTLV-I; (b) human mononuclear cells other than T lymphocytes are efficient targest for HTLV-I. Efforts are being made to track the presence of HTLV-I inside B cells and monocytes.

Th.C.P.4 PROTEASE ACTIVATION DURING HIV INFECTION IN A CD4 POSITIVE CELL LINE

Piedimonte, Giuseppe* ; Petronini, P.G.* ; Guetard, D.** ; Favier, V.** ; Borghetti, A.G.* and Montagnier, L.**
* Istituto di Patologia Generale, Universita di Parma, Italy ; ** Viral Oncology Unit, Institut Pasteur, Paris, France.

Objective. To investigate the mechanism of cytopathic effect of HIV in a CD4+ cell line.
Methods and results. HIV infection of CEM CD4+ cell line results in an early inhibition of proliferation rate and of overall cellular protein synthesis, much long before the synthesis of viral proteins and production of virus. A specific band of 96Kd was particularly inhibited. In addition, when cells were incubated under particular conditions in serum-free medium, a larger degradation of proteins was observed in comparison to controls. An increased activity of protein degradation was observed also in vitro with extracts obtained from HIV-infected cells and incubated in the presence of endogenous or exogenous labelled substrates. This proteolytic activity was blocked by inhibitors of serine-proteases. Extracts from cells infected with heat-inactivated HIV did not show a similar degradative activity.
Conclusion. The induction or activation of latent proteases during the development of the HIV-infection may be an important factor in HIV-induced cytopathic effect and AIDS pathogenesis.

Th.C.P.5 CONCOMITANT INFECTION WITH HUMAN T CELL LYMPHOTROPIC VIRUS II (HTLV II) AND HIV-1

Hall,William M*;Kaplan MH*;Farber B*, Coronesi M*;Salahuddin SZ**Oyaizu N*;Nagashima K***. *North Shore University Hospital, Cornell University, Manhasset, NY.,U.S.A.**NCI, Bethesda, Md.,***University of Hokkaido, Sapporo, Japan.

Object: To study concomitant infection of HIV and HTLV I/II
Methods:HIV patients(pts) were screened for antibody (Aby) to HTLV I/II. Aby +sera was confirmed using Western blot technology and radioimmunoprecipitation technology (RIPA) to purified HTLV I MO-1 and HTLV II 580B. Peripheral blood lymphocytes were grown with IL-2 and PHA. After rounds of lysis, surviving cells were cocultivated with cord blood lymphocytes (CBLs) and continuous cell lines established. Viral isolation was confirmed with reverse transcriptase assay, electron microscopy and Southern hybridization technology.
Results: 30 sera from 383 HIV individuals had Aby to HTLV I/II mostly in older intravenous drug users (IVDU). 6 new isolates of HTLV II were made from 6 IVDUs. 3 isolates of HTLV I were made from 3 HS pts. Patients with HTLV II had ichthyosis,dermatopathic lymphadenopathy and staph infection. Those with HTLV I had Tropical spastic paraparesis and CD-8 chronic leukemia. Restriction enzyme mapping of 4 strains of HTLV II showed all 4 were similar to 2 previous isolates of HTLV II (Mo and NRA) indicating that the virus of HTLV II is highly conserved.
Conclusion: Significant HTLV II infection is in New York IVDU's.

Th.C.P.6 ENVELOPE CROSS-REACTIVITY BETWEEN HIV-1 AND HIV-2

Böttiger Blenda*, Karlsson A**, Naucler A*, ***Andreasson P-A, ****Mendes Costa C, and Biberfeld G*.
*National Bacteriological Laboratory, and **Södersjukhuset, Stockholm, Sweden, ***National Public Health Laboratory and ****National Hospital Simao Mendes, Bissau, Guinea-Bissau.

Objective. To study cross-reactions of HIV-1 and HIV-2 positive sera against HIV-1 and HIV-2 with different serological methods.
Methods. Sera from HIV-1 infected Swedish homosexual men and from HIV-2 infected blood donors and patients with AIDS related symptoms from Guinea-Bissau were tested by Western Blot (WB), radioimmunprecipitation (RIP) and neutralization assays using both HIV-1 and HIV-2 antigens.
Results. The HIV-1 positive sera cross-reacted with the envelope glycoproteins of HIV-2 in 2/24 (8%) in WB and in 10/48 (21%) in RIP assays. The HIV-2 positive sera cross-reacted with the envelope glycoproteins of HIV-1 in 15/38 (39%) in WB and in 13/27 (48%) in RIP assays. Cross-neutralization was observed in 20/57 (35%) and 16/43 (37%) of the HIV-1 and HIV-2 positive sera, respectively.
Conclusion. Serological cross-reactivity between HIV-1 and HIV-2 envelope glycoproteins is observed in both WB, RIP and neutralization assays. Cross-reactions against envelope glycoproteins are seen more often in RIP than in WB assays.

Th.C.P.7 PROSPECTIVE STUDY OF NEWBORNS TO HIV SEROPOSITIVE MOTHERS : PRONOSTIC VALUE OF ANTIGENEMIA AND ANTIBODIES WESTERN-BLOT ANALYSIS

Rouzioux Christine*, Mayaux M.J.**, Jacomet C.*, Blanche S.*, Griscelli C.*
and French HIV infection in Newborn Collaborative Study Group.
* : Hôpital NECKER, Paris, France ; ** Inserm U.292, Kremlin-Bicêtre, France.

Objective : The results of two virological parameters evaluated at 9 months of age were correlated to the clinical status at the age of 18 months, among 86 children born to HIV seropositive mothers.

Methods : 415 infants have been prospectively followed since birth, in a multicentric French study. Among 200 children born 18 months earlier or more, 86 evaluated in the same laboratory were included in this analysis. HIV1 antibodies were studied by Western Blot analysis (Diagnostics Pasteur or Dupont de Nemours) and classified into two groups : 1 = negative or incomplete pattern ; 2 = positive pattern, with antibodies to proteins of gag, pol and env genes. The detection of antigenemia was performed by immuno-capture assay (Abbott or Diagnostics Pasteur). At 18 months of age the children were classified into two groups according whether they had presented HIV related clinical symptoms or not.

Results : The percentage of children with clinical symptoms is 28 % at 18 months of age. This percentage significantly differs according to positive or negative antigenemia at 9 months of age (100 % vs, 18 % respectively, $p < 10^{-6}$). The same pattern is observed with Western-blot (89 % when positive, vs 11 % when negative or incomplete, $p < 10^{-9}$). As the two virological parameters were correlated, adjustment test has been performed, each of the two factors is associated to the clinical status independently of the other.

Conclusion : The presence of a complete pattern of Western-blot or of a positive antigenemia at 9 months of age are highly predictive of the appearance of clinical symptoms at 18 months of age or earlier.

Th.C.P.8 THREE DIMENSIONAL ELECTRON MICROSCOPY OF HIV-INFECTED MACROPHAGES (IN VITRO AND IN VIVO)

Cph. Bron[1], J. Jendis [1], J. Fleury [5], Ph. Gremillet[4], D. Launay[3], M. J.[4],Th. B.[2], J. Sch.[1]
[1] Swiss National Center for Retroviruses, [2] Central Electron Microscopy Laboratory, Institute for Immunology and Virology, Zürich, and [3] Computimage GmbH, Switzerland.
[4] Laboratoire du Traitement du Signal et Instrumentation, Université de Saint-Etienne, et
[5] Service d'Anatomie-Pathologique, CHU Henri Mondor, Créteil, France.

Objective: Analysis of the 3-D ultrastructure of HIV-infected macrophages in vitro and in vivo (bronchoalveolar lavages) and comparison with similar non infected cells.

Methods: Computer aided volumic ultra microscopy based on serial sections (20 to 40 nm) containing laser-induced topographical references allows a 3-D reconstruction of entire cells via digital processing of electron microscopic images.

Results: The 3-D analysis offers an improved knowledge of cell ultrastructure and documents the fine cytopathic effects of HIV. The detailed results will be presented on a computer display.

Conclusion: The computer-assisted 3-D analysis has potential advantages and proved particularly powerful in the study of HIV-infected cells. The methodology will be useful to delineate new approaches for evaluation of therapeutic agents.

Th.C.P.9 THE HIV1 PRODUCTION IN PERIPHERAL BLOOD MONONUCLEAR CELLS IS INHIBITED BY ANTI-B2 MICROGLOBULIN MONOCLONAL ANTIBODIES.

CORBEAU P., DEVAUX C., BOUTRAIT J., REY F., KOURILSKY F. and CHERMANN J.C.

Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cédex 9 - FRANCE

We have recently searched for monoclonal antibodies (mab) interfering with HIV production. The "in vitro" assays used for the screening were designed for rapid identification of mab interfering either with entry, replication or budding of the virus. Most of the anti-B2-microglobulin (B2m) mab tested strongly delayed HIV1 production by peripheral blood mononuclear infected cells.

Our recent data suggest that anti-B2m mab do not inhibit HIV entry since cellular pre-incubation with these mab do not prevent HIV production, and therefore interfer rather after virus penetration during the viral replication cycle, either on the replication or the viral particle budding. Preliminary investigation demonstrates that inhibition is efficient if mab is added to the culture only during the three first days following infection. However, no inhibition is observed when mab is added to the cells 24 H after the infection.

Finally, anti B2m - mab also delayed syncitia apparition among infected MT4 cells, but yet have no effect on HIV1 production by CEM cells.

Th.C.P.10 HIV-1 PROTEINASE INHIBITION BY CERULENIN.

Myra O. McClure*, Laurence H. Pearl*,***, Thomas F. Schulz*, Karin Moelling** & Marie-Theres Knoop**. *Inst. of Cancer Research, Fulham Road, London, UK; **MPI fur Molekular Genetik, Ihnstrasse 73, Berlin, FRG; ***Dept. of Crystallography, Birkbeck College, London, UK.

Objective: To determine the effect of Cerulenin on the activity of the HIV-1 encoded proteinase, and understand it's mechanism of action with the aim of designing specific proteinase inactivating compounds as anti-HIV drugs.

Methods: Recombinant HIV-1 proteinase was assayed for ability to cleave gag fusion proteins or synthetic peptides, after incubation of the proteinase with cerulenin. The effect of cerulenin on the cleavage of gag precursors, in H9 cells chronically infected with HIV-1LAV, was investigated by RIPA with HIV+ patient sera.

Results: Preincubation of HIV-1 proteinase with cerulenin for 15-30 mins, markedly diminished it's cleavage of gag fusion proteins and synthetic peptides. In infected cells, cerulenin inhibited cleavage of p55gag at concentrations which did not inhibit protein synthesis. At these concentrations HIV replication was significantly reduced. Higher doses of cerulenin were cytotoxic.

Conclusion: Cerulenin inhibits gag cleavage by inactivating the viral proteinase. Using the molecular structure of the active site of HIV proteinase we can model the likely binding mode and mechanism of action of cerulenin and design more specific and less cytotoxic anti-HIV compounds, which function by inhibiting the proteinase.

Th.C.P.11 ISOLATION OF HIV-2 STRAINS WITH DIFFERENT NEUTRALISATION PATTERNS.

Denise Whitby*, Thomas F. Schulz*, Hilton Whittle** and Robin A. Weiss*. *Institute of Cancer Research, Fulham Road, London, UK; **MRC Laboratories, Banjul, The Gambia.

Objective: To study the variability of HIV-2 isolated from patients with AIDS/ARC and asymptomatic seropositive individuals both with respect to primary sequence and biological phenotype, e.g. neutralization by sera of different origin, cytopathic effect, tropism for T-cells or monocytes.

Methods: Peripheral blood mononuclear cells from HIV-2 positive individuals in The Gambia were cultured with cord blood cells and checked weekly for reverse transcriptase. Established cell lines of T- and monocyte origin (H9, C8166, Molt4#8, U937) were added to cultures showing RT-activity or cytopathic effect to obtain permanent isolates. These were characterised by Southern blots, radioimmunoprecipitation assays (RIPA) and sensitivity to neutralizing antibodies. Fragments of the genome generated by PCR were cloned for sequencing.

Results: Among 4 new permanent isolates of HIV-2 made thus far one from an AIDS patient grows rapidly, one from an asymptomatic individual grows slowly,and the remaining two from ARC patients are intermediate. The former have been characterised by Southern blots and (RIPA) as HIV-2 viruses. Using PCR, regions corresponding to the tat gene and one portion of the env (bp 8070-8330) could be amplified from all 4 isolates. One region from the pol gene and from the env (bp 7441-8330) could only be amplified from 3 and 1 isolate, respectively. The isolates differed markedly in their susceptibility to neutralizing antibodies from HIV-1 and HIV-2 infected subjects.

Conclusions: Four new isolates of HIV-2 differ in their growth properties and susceptibility to neutralizing antibodies. Genome variability is being analysed.

Th.C.P.12 INHIBITION OF ENVELOPE OLIGOSACCHARIDE PROCESSING DIMINISHES HIV-1 INFECTIVITY

[illegible]: M Vander Heyden, and L Ratner. Departments of Medicine and Microbiology & Immunology, Washington University, St. Louis, Mo. USA.

Objective: Inhibitors of trimming glucosidases and mannosidases have been shown to reduce HIV-1 infectivity. This study focused on the effects of a potent glucosidase I and II inhibitor, N-butyl-deoxynojirimycin (N-buDNJ).

Results: With acute HIV-1 infection of H9 and CEM cells, concentrations ≥0.02 mM N-buDNJ completely inhibited syncytia formation, but virus production was reduced only at ≥2.0 mM, without cell toxicity. In chronically infected H9 cells, virus production was reduced 30% at doses of ≥2.0 mM but not at lower concentrations. The infectivity of HIV-1 produced from cells treated with 2.0 mM or 4.0 mM N-buDNJ was reduced 4-fold or ≥10,000-fold, respectively. Chronically infected cells treated with ≥0.01-0.1 mM N-buDNJ for ≥3 days showed impairment in their ability to form syncytia with uninfected T lymphoid cells. Immunofluorescent and radioimmunoprecipitation analyses demonstrated impaired expression of the envelope on the surface of N-BuDNJ treated infected cells, and increased molecular weight of the envelope proteins. Virus from N-BuDNJ treated cells demonstrated decreased binding to T lymphoid cells.

Conclusion: N-BuDNJ inhibits HIV-1 infectivity and syncytia formation by altering the processing of oligosaccharides on the HIV-1 envelope. The efficacy of this agent and its relative lack of toxicity suggest that clinical studies are indicated.

Th.C.P.13 1,25(OH)$_2$VITAMIN D$_3$ (1,25D) ENHANCES HIV-1 REPLICATION IN A MONOCYTE CELL LINE.

Skolnik, Paul *; Wang, M.*; Rota, T.**; Krane, S.**; and Hirsch, M.** *New England Medical Center, Tufts University and **Massachusetts General Hospital, Boston, MA, USA.

Objective. To determine whether 1,25D alters HIV-1 replication in-vitro. Methods. A3.5 cells (a monocyte cell line) were treated with 1,25D either before (Pre-Rx) or simultaneously with (Sim-Rx) the addition of HTLV-III$_B$. Cultures were assayed for HIV-1 p24 antigen production by ELISA; virus yield assays were also performed (expressed as TCID$_{50}$/ml). 1,25D (10 ng/ml) modulation of CD4 and HLA-DR expression was analyzed by staining with OKT4 and OKDR-FITC conjugates. Cultures of peripheral blood mononuclear cells (PBMC) from HIV-1 seropositive subjects were performed in the presence or absence of 1,25D (10 ng/ml) by cocultivation with PHA-P stimulated PBMC from seronegative donors and subsequent analysis for HIV-1 p24 antigen production. Results. 1,25D Pre-Rx of HIV-1 infected A3.5 cells increased p24 antigen production and virus yield on assay day 10 as follows:

	No	AZT	1,25D				(*=Not done)
	1,25D	1 uM	5pg/ml	100pg/ml	1ng/ml	10ng/ml	100ng/ml
p24 (ng/ml)	0.91	0.54	1.54	1.92	13.25	557.0	2286.0
virus yield	$2x10^3$	ND*	ND	ND	$2x10^4$	$1x10^6$	$1x10^7$

Similar results were obtained on other assay days and with Sim-Rx cells. 1,25D did not decrease cell number or viability. 1,25D did not alter CD4 or HLA-DR membrane expression. p24 antigen in 1,25D-treated PBMC cultures from 2 of 4 HIV-1 infected subjects was increased 10-fold compared with controls. Conclusions. 1,25D enhancement of HIV-1 replication may be important for improved HIV isolation from clinical samples and treatment of HIV infection.

Th.C.P.14 STIMULATION OF HIV EXPRESSION IN B LYMPHOCYTES BY B CELL GROWTH FACTOR

Gupta, Phalguni; Thampatty, P.; Balachandran, R. and Rinaldo, C.R. University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To study the role of B cell growth factor (BCGF) in HIV expression.
Methods. Peripheral blood lymphocytes (PBL) were preincubated with B cell growth factor (BCGF) for 48 hr, infected with HIV, and then cultured in the presence of BCGF. HIV expression was monitored by the antigen capture test and by measurement of HIV-specific RNA.
Results. BCGF increased the production of HIV 10-20 fold in PBL. The increase of virus production was associated with an increase in HIV RNA production. BCGF had no stimulatory effect on HIV production in T cell enriched cultures; BCGF also did not have any proliferative effect on these T cells. This indicates that BCGF-induced stimulation of HIV is a B cell mediated phenomenon. BCGF enhanced expression of HIV was not associated with induction of GM-CSF, IL-1B or IL-2. Anti-IgM antibody was found to inhibit the stimulatory effect of BCGF. Such suppressive effect of anti-IgM antibody was found to be associated with an increased expression of interferon.
Conclusion. In the presence of BCGF, B lymphocytes can be infected with HIV and produce high levels of virus. BCGF-induced HIV expression is down regulated by anti-IgM antibody. These data suggest that HIV replication in B cells may be of significance in the immunopathogenesis of the retrovirus.

Th.C.P.15 CELLULAR CONTROL, BUT NOT ENTRY DOWN REGULATE HIV-1 EXPRESSION IN NEURAL CELLS.

Mizrachi, Yaffa; Sinangil, F; Volsky, D.J. St. Lukes\Roosevelt, Columbia University, New York, USA.

Objectives. To analyze rate limiting steps of HIV-1 expression in neural cells.
Methods. Astroglia and neuroblastoma cell lines were used as an in vitro model system for HIV-1 neuropathogenesis. Viral expression in these cells was analyzed following infection and transfection. Using the membrane dequenching technique, viral entry was analyzed in parallel to p24 antigen accumulation in the cells.
Results. Significant variability was detected among different HIV-1 isolates in their ability to infect neural cells. Low producing non cytopathic viral expression was found in some cell lines. One cell line, did not produce virus under any circumstaces. We studied whether viral entry is a possible rate limiting step in infection of these cells.

Cells	%DQ	p24 antigen(pg/ml)	virus production
U251	23.5	312	+
TE671	15.5	397	+/-
SK N MC	8.0	550	+/-
LA N 1	15.0	335	-
Jurkat	19.0	5700	++++

Conclusion. Our data show that intracellular control, rather than virus entry, restricts HIV-1 expression in neural cells.

Th.C.P.16 LATENT/INDUCIBLE EXPRESSION OF HIV-1 IN GLIAL CELLS

Helen Kim, Shahabuddin, M., Mizrachi, Y. and Volsky, D.J. St. Luke's/Roosevelt Hospital Center and Columbia University, College of Physicians & Surgeons, New York City, NY U.S.A.

Objective. To determine the conditions for HIV-1 latency/induction in chronically-infected human glial cells.
Methods. HIV-1 induction was determined by following an increase in: i) intracellular HIV-1 RNA; ii) intracellular and extracellular HIV-1 p24 protein; iii) HIV-1 tat and art gene product as determined by reporter CAT gene expression; iv) production of infectious virus.
Results. Human glioma cells H-80/N1T-E, latently infected with HIV-1 (strain N1T-E), could be induced to increased HIV-1 replication by treatment with Na-butyrate or heat shock, but not with PMA or HHV-6, which are known to induce virus in T cells (Table). Virus induction resulted in a change of the pattern of virus-specific proteins, release infectious virus, but not cytolysis or cell fusion.

Inducer	HIV-1 production (p24, pg/ml sup.)
None	4,800
PMA (20 ng/ml)	3,200
Na-Butyrate	23,000
IL-2	5,700
HSV-6	4,000
Heat Shock	20,000

Conclusions. Human glial cells are capable of carrying latent HIV-1 infection. Cells can be induced to produce infectious HIV-1, which could contribute to the spread of HIV-1 in the brain. The mechanism of induction appears to differ from that in T lymphocytes.

Th.C.P.17 DIFFERENCES AMONG HIV ISOLATES IN CELLULAR ENTRY AND FUSOGENICITY AS MEASURED BY FLUORESCENCE DEQUENCHING TECHNIQUE.

Sinangil, Faruk; Mizrachi, Y. and Volsky, D.J. St. Luke's/Roosevelt Hospital Center and Columbia University, College of Physicians & Surgeons, New York City, NY, U.S.A.

Objective. To compare the fusogenic properties of different strains of HIV and their ability to enter and infect various target cells.
Methods. Six strains of HIV (N1T-E, N1T-A, HTLV-III-B, RF-2, SF-3 and SF-33) were gradient purified and labelled with octadecylrhodamine B chloride (R-18). Various lymphoid, monocytic, glial, neuroblastoma cell lines and fresh lymphocytes were incubated with labelled virus and DQ values were calculated from fluorescence measurements. Viral entry was confirmed by measuring intracellular RNA and p24 antigen levels. Infection was followed by immunofluoresence.
Results. Our data demonstrates that HIV enters cells by a rapid, receptor-mediated and temperature-dependent process of fusion with plasma cell membrane. Different HIV isolates showed significant variability in their ability to fuse with various target cells as measured by DQ technique. Viral nucleocapsid entry and infection were correlated with the fusogenic properties of each isolate.
Conclusion. Our data provide quantitative measure of HIV-strain differences with respect to virus entry and fusogenic properties.

Th.C.P.18 THE ROLE OF THE *vpu* GENE IN HIV-1 LIFE CYCLE

Zene Matsuda, Matsuda, M. ; Essex, M. and Lee, T. H.
Boston, MA U.S.A., Harvard School of Public Health

Objective. The presence of the *vpu* gene distinguishes HIV-1 from HIV-2. The vpu product is a 16Kd protein and elicits antibody response in HIV-1 infected individuals. The function of *vpu* gene is not fully understood. One study suggested the involvement in maturation of virion and seems to be required for the efficient replication in T cells. Another group suggested a possible role as a negative regulator. Objective of this study is to elucidate the function of *vpu* gene of HIV-1 in its life cycle.
Methods. Mutagenesis by linker insertion, deletion, and site directed mutagenesis were applied for the *vpu* gene of an infectious clone of HIV-1, and each mutant was analyzed in comparison with the wild type.
Conclusion. Some of the mutants in *vpu* gene affected a growth pattern of HIV-1 in T cells. The differences in RT activity, CPE, the expression of viral antigens will be presented and the possible mechanism of *vpu* function will be discussed in DNA, RNA, and protein level.

Th.C.P.19

MOLECULAR INTERACTIONS BETWEEN HHV-6 AND HIV-1 IN COINFECTED CD4+ T-CELLS LEAD TO INCREASED HIV-1 GENE EXPRESSION

Ensoli, Barbara; Lusso, P.; Schachter, F.; Rappaport, J.; Josephs, S. and Wong-Staal, F. *et al*.
Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD. U.S.A.

HHV-6 can superinfect HIV-1 infected human CD4+ T-cells, leading to increased and accelerated cell death. HHV-6 infected cells are also capable of stimulating expression of a reporter gene linked to the HIV-1 LTR. Increased HIV-1 LTR *trans*-activation is obtained when HHV-6 infected cells are co-transfected with the HIV-1 *tat* gene, or when doubly infected cells are used. In fact, sequences necessary for HIV-1 activation by HHV-6 are distinct from those required for the *tat* response and map to a region of HIV-1 LTR where nuclear proteins, activated or induced by HHV-6 infection, specifically bind. Increased levels of HIV-1-specific transcripts are seen by *in situ* hybridization in HHV-6/HIV-1 doubly infected cells as compared to single HIV-1 infection. These data suggest that since both viruses, HHV-6 and HIV-1, share similar cell tropism, coinfection of CD4+ T-cells may play an important role in the progression of HIV-1 infection to AIDS.

Th.C.P.20

INDUCTION OF HUMAN IMMUNODEFICIENCY VIRUS EXPRESSION BY ULTRAVIOLET LIGHT

Sadaie, M. Reza*; Tschachler, E.*; Valerie, K.**; Rosenberg, M.**; Felber, B.K.***; Pavlakis, G.N.***; Wong-Staal, F.*
*Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD; **Smith, Kline and French, King of Prussia, PA; ***BRI-Basic Research Program, National Cancer Institute, Frederick, MD, USA

Objective. Recent data demonstrate that ultraviolet (UV) light and certain chemical agents activate transcriptional level of HIV-1 LTR-directed gene expression. We have examined effect of UV on activation of HIV-1 promotor in an attempt to elucidate mechanisms by which UV light may induce a latent virus. Methods. We have developed several human cell line clones each containing a distinct form of a stably integrated *tat*/*rev* mutant HIV-1 provirus. Adherent (HeLa) and non-adherent (H9) cells expressing *tat* constitutively have been used in amplification of virus release after UV treatment. Results. UV irradiation leads to activation of latent HIV-1 which is transmissible to CD4+ H9 cells. Characteristic syncytial cells and simultaneous virus propagation comparable to wild type were observed as early as two weeks after UV treatment. UV was highly effective for *tat*(-), but not for *rev*(-) mutants under identical conditions. Conclusion. These findings raise the question of whether natural exposure to UV light might contribute to the pathogenesis of AIDS. We propose that UV radiation of skin might directly or indirectly activate latent virus resident in human epidermal Langerhans cells and/or subepidermal lymphocytes.

Th.C.P.21

ISOLATION OF HIV IN A HIV1-HIV2 DUAL SEROCONVERTED CHILD INFECTED BY BLOOD TRANSFUSION IN 1984 IN FRANCE : CHARACTERIZATION WITH PCR

Rouzioux Christine*, Burgard M., Courgnaud V., Bréchot C., Gaumgel C., Berche P. *et al* .
Hôpital NECKER-ENFANTS MALADES, Paris, France.

Objective : By means of a seroepidemiological study among 144 patients multitransfused in France, we found one true dual seropositivy for HIV-1 and HIV-2. This child with Von Willebrand's disease was transfused on a first and unique occasion in April 1984. We have chosen to use the selective DNA amplification technique by polymerase chain-reaction (PCR) to type the proviral sequences, specific for HIV-1 or HIV-2.

Methods : Sera were tested with both specific type EIA, Western-blot (HIV-1 or HIV-2 from Diagnostics Pasteur) and with peptides immuno-assays (from a conserved region of the transmembrane protein : Diagnostics Pasteur). Proviral DNA sequences were studied by PCR using primers and probes for HIV-1 (pol and env regions) for HIV-2 (gag, env and LTR regions).

Results : The serological analysis of patient's sequential sera (from April 1984 to Dec. 1988) using three specific techniques, shows : - a true double reactivity for both viruses ; - a simultaneous double seroconversion between April and May 1984 ; - a profound decrease of anti-p24 antibodies between 1984 and 1988 (in contrast the titer of HIV-2 antibodies directed against p26 persisted at a high level). DNA proviral sequences were detected by PCR for pol and env regions of HIV-1, and for gag and LTR regions of HIV-2. These results were obtained from the different viruses isolated by cocultures and from the peripheral lymphocytes of the patient.

Conclusion : This dual positivity obtained by serology and by PCR in a French patient raises the possibility of a dual HIV1-HIV2 infection or of an infection by a third virus containing both HIV-1 and HIV-2 related sequences.

Th.C.P.22

Binding Characteristics of HIV-1 and HIV-2: Differences in Binding Inhibition by Soluble CD4 and Dextran Sulfate.

Looney,D.[1]; Mitsuya, H.[2]; Franchini,G.[3]; Broder,S.[2]; Redfield,R.[1]; and Wong-Staal, F.[3]. [1]Walter Reed Army Institute of Research, Washington, D.C. .[2]DCT COP,NCI,Bethesda, MD.. [3] LTCB, NCI, Bethesda, MD.. U.S.A.

Objectives: Examine binding characteristics of different HIV- 1 and HIV-2 viruses, and binding inhibition by soluble CD4 (sCD4) and dextran sulfate.
Methods: Viruses (HIV-1: HXB2D, HX10, WMJ-1, HTLV-III$_B$; HIV-2:HIV-2$_{ROD}$, HIV-2$_{DZ}$, SBL666 clone ISY, and SIV$_{MAC}$) were labeled using 5,6-^{3}H uridine, and binding and binding inhibition assays performed on H9 and Molt-3 cells.
Results: Binding affinities were similar for HIV-1 and HIV-2, but numbers of saturable binding sites varied eight-fold. HIV-2 viruses were much less susceptible to binding inhibition by sCD4, while OKT4a monoclonal antibody and dextran sulfate inhibited binding of HIV-1 and HIV-2 in an identical fashion. These differences may reflect the involvement of accessory cell surface molecules in HIV-2 binding or penetration; however, differences in the structural relationship or the stability of envelope proteins in HIV-1 and HIV-2 is suggested by the presence of differing ratios of sCD4-detectable envelope protein in purified virions and virus-free supernantants from HIV-1 and HIV-2 infected cultures.

Th.C.P.23

CHARACTERIZATION OF NEF GENES FROM SIV AND HIV2.

Kestler, Harry W, Li Y, Butler CV, Daniel MD, Desrosiers RC.
New England Regional Primate Research Center, Harvard Medical School, Southborough, MA USA

Objective. To compare the nucleotide sequence of NEF genes and to examine the function of the NEF gene *in vitro* and *in vivo*.
Methods. Infectious molecular clones of SIV and HIV2 were subcloned into plasmid and M13 vectors for sequencing and mutagenesis. DNA sequencing was performed using the primer directed dideoxy method. Genes were mutated by oligonucleotide directed gap mutagenesis or by restriction site specific mutagenesis. Virus was obtained by transfecting cloned DNA with DEAE dextran.
Results. Mutations that alter the size and content of NEF are common in infectious molecular clones. The SIVmac239 NEF gene contains a TAA in-frame stop signal 93 codons from the initiating ATG predicting a protein product 65% shorter than that of SIVmac142. A premature truncation of NEF is also observed in clones SIVmac251 and HIV2rodCVB. SIV142 encodes a NEF in which a segment of 15 amino acids are different from the other sequenced NEF genes. The introduction of a frameshift mutation that removes 74% of NEF coding sequences in the SIV142 cloned virus did not affects its ability to replicate in HUT78 cells. A single nucleotide has been changed in SIV239 to create a fully open NEF reading frame in this cloned virus; the properties of SIV239 with open, truncated, and deleted NEF genes are being compared both in cultured cells and in infected macaque monkeys.
Conclusion. Changes that obviate NEF expression occur frequently in infectious molecular clones of SIV and HIV2. These findings are consistent with the proposed role of NEF in mediating repression of viral gene expression. Mutational analysis of the NEF gene is complicated by difficulties in defining the sequence of functional, wild type NEF.

Th.C.P.24

IN SITU HYBRIDIZATION ANALYSIS OF HIV RNA INDUCTION IN U1 CELLS TREATED WITH PHORBOL ESTER

Russo, H.*, Maltzman, W.*, Sellers, B.**, Saunders, A.**, Laurence, J.** and Rosenstraus, Maurice*.
*Enzo Biochem, Inc., New York, New York, USA, **Cornell University School of Medicine, New York, New York, USA.

Objective. To determine the kinetics of RNA production following activation of latent HIV infection at the cellular level using non-radioactive *in situ* hybridization.
Methods. Cultures of U1 cells, which contain 2 copies of latent HIV provirus, were treated with 5 ng/ml phorbol myristate acetate (PMA) and were maintained at 5-10X10^5 cells/ml. At various times, the cells were deposited on microscope slides and fixed with ethanol. HIV RNA in the fixed cells was hybridized to a biotinylated DNA probe that contained the entire HIV genome. The hybridized probe was detected using a streptavidin-alkaline phosphatase complex. The assay was completed in 4-5 hours.
Results. In untreated control U1 cultures, 0.5% of the cells expressed detectable levels of HIV RNA. At 24, 48 and 72 hours after exposure to PMA, the fraction of cells expressing detectable levels of HIV RNA increased to 32%, 67% and 60%, respectively. The amount of RNA per cell varied considerably as indicated by the intensity of staining. Uninduced cultures contained about 4500 cpm/ml of reverse transcriptase activity. The reverse transcriptase activity increased 1.9, 4.0 and 3.4 fold at 24, 48 and 72 hours after exposure to PMA.
Conclusion. *In situ* hybridization is a more sensitive indicator of HIV induction than reverse transcriptase activity since the extent of induction observed is much greater. Additionally, heterogeneity at the cellular level is revealed. This technique may be used to study HIV induction under other conditions and to evaluate the effect of putative inhibitors on HIV expression.

Th.C.P.25

NON-RADIOACTIVE IMMUNOPRECIPITATION ASSAY AS CONFIRMATORY TEST FOR ANTIBODIES TO HTLV-I VIRUS.

Tai, Cheng-Chih; Alexander, S.; Lillehoj, E.; Ting, R. C.
Biotech Research Laboratories, Inc., Rockville, MD 20850, USA.

Objective. To develop a non-radioactive confirmatory test for the detection of antibodies to HTVL-I envelope protein in human sera as a convenient alternative to the radioimmunoprecipitation assay (RIPA).
Methods. The envelope glycoproteins were immunoprecipitated by HTLV-I-positive sera or by a rabbit antiserum, resolved on SDS-PAGE, transblotted on a nitrocellulose membrane and visualized with the current Western blot (WB) system.
Results. A confirmatory WB method, similar to that used for the HIV-1 antibody test, has not been successfully applied to HTLV-I antibody screening because the envelope protein is not readily detected. RIPA is currently employed for this purpose since it is a sensitive assay, particularly for the detection of the envelope protein. A non-radioactive immunoprecipitation (IP) approach, applying the principles of both RIPA and WB, readily detected the envelope precursor protein, gp61/68, with a sensitivity approaching that of RIPA, thus circumventing the problems associated with use of radioisotopes. The following table shows the relative detectability of the key antigens of HTLV-I by the present system (IP/WB) as compared to that of WB and RIPA.

	gp61/68	p24, p26/28	p19	p38 (tax)
IP/WB	+	+	+	+
WB	-	+	+	+
RIPA	+	+	-	+

Conclusions. The IP/WB system is sensitive, convenient and useful as an alternative confirmatory antibody test for HTLV-I. Since immunoprecipitated gp61/68 are readily reactive with HTLV-I-positive sera on WB, it provides a technical basis for purification of these proteins by affinity chromatographic means for the future development of the HTLV-I WB assay system.

Th.C.P.27

COMPLEMENTATION OF HIV-1 rev MUTANTS BY rex PROTEIN OF HTLV1 BUT NOT BY rex OF BLV

Felber, Barbara K.*, Derse, D.**, Athanassopoulos, A.*, Pavlakis, G. N.*
*BRI-Basic Research Program, & **LVC, NCI-FCRF, Frederick, MD 21701, USA

Objective. To test functional similarities of rev protein of HIV-1 and rex proteins of HTLV-1 and bovine leukemia virus (BLV).
Methods. rex proteins of HTLV-1 or BLV were expressed using the RSV promoter and SV40 polyadenylation site. pREX-BLV contains the two rex exons joined by site-directed mutagenesis; thus splicing is not required for rex expression by these plasmids. In addition, the initiator AUG region was mutagenized to improve the homology to the initiator AUG consensus, in an effort to improve translation efficiency. pREX-HTLV1 contains the HTLV-1 rex coding sequence and is otherwise similar to pREX-BLV.
Results. HIV-1 rev proviral mutants show an increase in multiply spliced mRNA at the expense of the unspliced mRNA. These mutants produce low levels of gag and env structural proteins. Cotransfection of the rev mutants with a rev-producing plasmid results in full complementation of these defects. Partial complementation was also obtained by HTLV-1 rex but not by the BLV-1 rex. rev acts via a cis-acting element in the env region of HIV-1 (rev-responsive element, RRE) and affects the transport and stability of RRE-containing mRNAs. Deletion mutants affecting RRE have been studied, to identify the mechanism of function of rev and rex proteins.
Conclusion. rev and rex proteins are essential for viral replication. rex of HTLV-1 complements rev mutants, whereas rex of BLV does not. Thus HTLV-1 rex is functionally related to rev. Examination of the role of these proteins reveals that they may affect the nuclear transport of the viral mRNA.

Th.C.P.29

INTERFERONS (IFN) AND BACTERIAL LIPOPOLYSACCHARIDE (LPS) PREVENT HIV INFECTION IN MACROPHAGES BY BLOCKING PROVIRUS FORMATION.

R.S. Kornbluth, P.S. Oh, J.R. Munis, P.H. Cleveland, and D.D. Richman. Univ. Calif. San Diego and the V. A. Medical Center, San Diego, CA, U.S.A.

Objectives. To examine the effects of macrophage-activating agents on HIV replication.
Methods. Monocyte-derived macrophages were treated with various substances and then infected with a macrophage-tropic strain of HIV-1 (HTLV-III$_{\text{Ba-L/85}}$).
Results. (1) Pretreatment with IFN-α, IFN-β, IFN-γ, or LPS prevented viral replication in macrophages. In treated cultures, little or no infectious HIV or p24 core antigen was released into the supernatant, no virions were seen by electron microscopy, no viral RNA or DNA was detectable in the cell lysates, and no cytopathology (as determined by multinucleated giant cell formation) occurred. In contrast, a wide dose range of recombinant IL-1β, IL-2, IL-4, IL-6, M-CSF, TNF-α, or lymphotoxin was ineffective. A consistent effect of GM-CSF was not observed. (2) Pretreatment with ~100 U/ml of IFN-α, ~ 10 U/ml of IFN-β, or ~100 U/ml of IFN-γ was sufficient to prevent virion release maximally and to prevent cytopathology completely. Transforming growth factor β (TGFβ) at 1 ng/ml reverses the protective effects of low doses of interferons and LPS, consistent with the known macrophage "deactivating" effects of TGFβ. (3) Using the polymerase chain reaction, little or no proviral DNA was present in macrophages pretreated with interferons or LPS. Thus, these agents prevent the establishment of the proviral DNA genome in these cells.
Conclusion. HIV replication in previously uninfected macrophages can be regulated at the level of provirus formation by an inducible host cell mechanism. These findings may explain the restricted replication of HIV in macrophages *in vivo* and suggest an antiviral role for interferons in the therapy of HIV infection.

(Supported by NIH AI-25316, AI-62548, EY-3093, and by the Veterans Administration.)

Th.C.P.26

PURIFICATION OF HIV IN AN AQUEOUS TWO-PHASE SYSTEM RETAINS THE INFECTIOUS TITER AND GIVES A HIGH YIELD OF gp120

Hammar, Lena* and Gustav Gilljam**.
*Dept. of Veterinary Virology, Biomedical Center, Uppsala and **Dept. of Virology, National Bacteriological Laboratory, Stockholm, Sweden.

Objective. Concentration of HIV by centrifugation results in a low recovery of the external glycoprotein. This is consistent with what is found with other retroviruses. Extraction in two-phase systems based on water soluble polymers were recently tested with the feline leukemia virus and the bovine leukemia virus (Hammar et al, J Virol Meth, and Biotech & Appl Biochem, 1989, in press). As the results with these viruses were promising we apply the same technique for the purification of HIV.
Methods. Several polymer-based aqueous two-phase systems (Albertsson, Biochim Biophys Acta, 1958;27:378-395) were tested for their capacity to enrich the HIV from HIV-1$_{\text{IIIB}}$ infected H9 cell culture medium. The infectivity titer and content of gp120 and p27 were determined.
Results. With a system composed of dextran and polyethylene glycol the two viral proteins were both recovered to about 60% in a small volume bottom phase, about 200-fold concentrated. The infectious titer was fully retained in this fraction, in which the two viral proteins were about 100-fold purified on protein basis.
Conclusion. Partition in aqueous polymer-phase systems seems a useful principle for the concentration and purification of HIV directly from the infected cell culture medium. Fully sealed vessels or continuous flow design of the technical set-up would be possible to construct for convenience and safety.

Th.C.P.28

ANALYSES OF UNINTEGRATED VIRAL DNA AND CYTOPATHIC EFFECT (CPE) INDUCED BY HIV

Masuda,Takao and Harada,S.
Institute for Virus Research, Kyoto University, Kyoto, 606 Japan.

Objective. To delineate the relation between the accumulation of unintegrated HIV DNA and CPE induced by HIV infection.
Methods.The unintegrated HIV DNA was examined in ① acutely infected MOLT-4#8 cells with cell-free virus,② persistently infected cells (PICs) treated by TPA,③ PICs after induction of fusion by polyethylene glycol (PEG).For detection unintegrated HIV DNA,DNA was extracted from infected cells by Hirt method and analysed by Southern blotting method using BH10.
Results.The parallel relation between the accumulation of the unintegrated HIV DNA and the appearance of CPE was observed when MOLT-4#8 cells were acutely infected with cell-free virus and when PICs were co-cultured with uninfected MOLT-4#8 cells. PICs with or without TPA treatment did not produce any detectable amount of unintegrated HIV DNA. PEG treatment of PICs caused ballooning degeneration as seen in acute viral infection and unintegrated viral DNA was detected.
Conclusion.The accumulation of the unintegrated HIV DNA was observed when CPE was induced either by cell-free virus or co-cultivation with PICs, but not when cell-killing and enhanced viral replication was induced by TPA treatment. These data suggest that different cell-killing mechanisms may be present. Since the unintegrated HIV DNA was not detectable in PICs and its appearance in PEG-treated PICs, we hypothesize that some negative regulation factor is present in the PICs to suppress the synthesis of viral DNA and PEG-treatment released this negative factor. Further studies are undergoing to find out this negative regulation mechanism.

Th.C.P.30

CHARACTERIZATION OF HTLV-I CELL LINES DERIVED FROM U.S. PATIENTS WITH SPASTIC PARAPARESIS.

Lairmore, Michael; De, B.; Khabbaz, R.; Janssen, R.; Kaplan, J.; and Folks, T., Centers For Disease Control, Retrovirus Diseases Branch, Atlanta, Georgia, USA.

Objective: Determine characteristics of HTLV-I cell lines derived from U.S. patients with spastic paraparesis (SP).
Methods: PBMC or CSF cells were obtained from 4 patients with a clinical history of SP. Cell lines were established by coculture. HTLV-I expression was assessed using IFA and HTLV-I & II PCR. Serum and CSF antibodies were detected by WIB and RIP assays. Results: HTLV-I positive cell lines were derived from 3 of 3 CSF samples tested and 4 of 4 PBMC samples tested. All 4 patients direct (non-cultured) PBMC samples were PCR positive using a HTLV-I specific pol primer pair and were negative using a HTLV-II specific primer pair. In comparison, direct PBMC PCR analysis from 2 seropositive blood donors indicated 1 donor was HTLV-I positive and the other HTLV-II positive. Direct PBMC samples of 2 donors with indeterminate serologic status (p19+ only) and 0 of 3 from seronegative donors were PCR negative for either virus. SP patients serum and CSF samples contained antibodies to all major HTLV-I proteins. Data will be presented concerning the phenotype of cell lines.
Conclusions: These results provide further evidence that HTLV-I associated SP occurs in the U.S. and demonstrates the usefullness of PCR in distinguishing between HTLV-I and HTLV-II. These HTLV-I positive CSF and PBMC lines allow comparison of U.S. HTLV-I isolates with other HTLV-I isolates.

Th.C.P.31 GENERATION OF HYBRID HUMAN IMMUNODEFICIENCY VIRUSES

Srinivasan, Alagarsamy*; Kalyanaraman, S.*; Desai, S.**; Devare, S.**; and Jannoun-Nasr, R.*; *Centers For Disease Control, Retrovirus Diseases Branch, Atlanta, GA, USA, **Human Retrovirus Department, Abbott Laboratories, Abbott Park, Illinois, USA.

Objective: To investigate the viral determinants underlying tropism and cytopathic effects of HIV, hybrid HIVs were generated.
Methods: Varying 5' or 3' proviral DNA fragments of biologically infectious HIV clones (HIV_{Zr6}, HIV_{SF-2}, $HIV_{HTLV\ III}$ and HIV_{CDC451}) were used as substrates for recombination. The proviral 5' or 3' DNA fragments were cotransfected into cells by calcium phosphate precipitation method and hybrid viruses released from the cells were quantitated by HIV antigen assay.
Results: Truncated HIV proviral DNAs with overlap homology were transfected into human rhabdomyosarcoma cells. HIV released from the cells were quantitated at the end of 3 and 5 days after transfection. Hybrid HIVs with different 5' and 3' ends were generated using the molecular clones. Hybrid HIVs were infectious upon inoculation into PBLs and their genetic structures were determined by Southern hybridization analysis.
Conclusion: Construction of hybrid HIVs based on compatible restriction enzyme sites present in viral DNA has limitations because of extensive variability between different HIVs. Homologous recombination methodology provides an efficient alternate method for generating hybrid HIVs.

Th.C.P.32 FACTORS INFLUENCING HOMOLOGOUS RECOMBINATION BETWEEN HIV DNAs IN CULTURED HUMAN CELLS

Srinivasan, Alagarsamy*; Kalyanaraman, S.*; Jannoun-Nasr, R.*; Raine, R.**; Benson, J.**; Swan, D.**, *Centers For Disease Control, Retrovirus Diseases Branch, **Centers For Disease Control, Biochemistry and Cell Biology Branch. U.S.A.

Objective: To analyze recombination between HIV DNAs, optimal conditions were determined using DNA transfection in cell cultures.
Methods: Recombinant plasmid substrates were constructed from HIV proviral DNAs (HIV_{Zr6}, $HIV_{HTLVIII}$ and HIV_{SF-2}). The success of recombination was measured by the production of viable hybrid virus. Polymerase chain reaction method was also used to characterize the cross-over junction.
Results: Substrate DNAs were transfected into cells. The process of recombination between HIV DNAs were shown to be dependent on homology between the truncated HIV DNAs and maximum with the concentrations of the DNA 3 ug and above for both single and double cross-over. Human RD cells at a concentration of $4x10^6$ showed maximum hybrid virus production. Also, DNA calcium phosphate precipitate exposure of cells for 8-12 hrs and an expression time of 3-5 days after transfection registered detectable amount of hybrid virus in the medium.
Conclusion: Optimal conditions for efficient recombination between HIV DNAs were determined. This is a powerful technique to generate hybrid viruses at any region of the genome.

Th.C.P.33 LOCALIZATION OF THE DEFECT IN HIV PROVIRAL DNA BY HOMOLOGOUS RECOMBINATION

Srinivasan, Alagarsamy; Kalyanaraman, S.; Butler, Jr. D., Jannoun-Nasr, R.; York, D. and De, B., Centers For Disease Control, Retorvirus Diseases Branch, Atlanta, Georgia, USA.

Objective. Homologous recombination methodology was used to localize the defect in a $HIV_{HTLV\ III}$ proviral DNA.
Methods. High molecular weight DNA extracted from H9/HTLV III cells was cleaved with Xba I enzyme and the proviral DNA was molecularly cloned. Clone designate Xba3 was subcloned in a plasmid vector and tested for the virus production by DNA transfection. Reverse transcriptase (RT) and antigen assays were used to quantitate the virus released from the cells transfected with the proviral DNA. Truncated proviral DNAs were generated using standard recombinant DNA techniques.
Results. The proviral clone Xba3 was transfected into human RD cells. Unlike other proviral DNAs, Xba3 DNA transfected cells did not release virus which could be quantitated by RT assay. In cotransfection experiements with HIV LTR-CAT, Xba3 was able to transactivate the HIV LTR-directed expression as other proviral DNAs. Cotransfection of the Xba3 DNA with other truncated proviral DNAs (5' end) was able to increase the virus antigen detected in the medium. 5' end of Xba3 was inactive whereas 3' end was active in cotransfection experiments involving homologous recombination.
Conclusion. The defect in an HIV proviral DNA was localized by using truncated viral DNAs in cotransfection experiments. This approach narrows the region for molecular analysis to identify the nature of the defect.

Th.C.P.34 HUMAN ANTIBODIES TO HIV-1 GP160 INHIBIT ATTACHMENT TO CD4

Back, Nicole*, Thiriart C.**, Van der Hoek L.*, Bruck C.**, Goudsmit J.*.
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, ** Department of Genetics, Smith Kline-RIT sa, Rixensart, Belgium.

Objective. To detect the presence in human HIV antibody positive sera of anti-gp160 antibodies inhibiting the binding of HIV-1 gp160 to the extracellular portion of CD4.
Methods. HIV-1 sera of 264 homosexual men, 20 hemophiliacs, 10 iv-drugusers and 9 HIV-2 antibody positive sera were tested in a competition immunoassay using soluble CD4 (sCD4). Rabbits were immunized with peptides covering the CD4 binding site or with the neutralizing epitope of the HIV-1 strain HTLV-IIIB.
Results. 18 to 50% of the HIV-1 antibody positive sera from the three AIDS risk groups reduced gp160-sCD4 binding by more than 80% at a 1:100 dilution, while HIV-2 antibody positive sera tested did not show such activity in our assay. Attempts to localize the binding site for these gp160-sCD4 inhibitor antibodies on the primary sequence of gp120 by using synthetic peptides encompassing the CD4 binding site on gp120 were not successful. Neutralizing antibodies to the V3 domain of gp120 did not inhibit binding of gp160 to sCD4.
Conclusion. Antibodies inhibiting the gp160-sCD4 binding were highly prevalent among HIV-1 seropositives and not in HIV-2 sera. They emerge at the moment of seroconversion indicating good immunogenic potential of this domain. Presence of antibodies to an HIV-1 gp160 portion involved in CD4 binding did not hamper or prevent disease progression.

Th.C.P.35 DISTINCTION BETWEEN HIV-1 AND HIV-2 INFECTION USING ANTIBODY RESPONSES TO ACCESSORY GENE PRODUCTS

Goudsmit, Jaap*, Dekker T.*, Boucher C.*, De Ronde A.*, Debouck Ch.**, Barin F.***.
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, ** Department of Molecular Genetics, Smith Kline & French Laboratories, King of Prussia, PA, USA, ***Laboratoire de Virologie, LHRU Bretonneau, Tours, France.

Objective. To distinguish HIV-1 or HIV-2 infection by serum reactivity to the accessory gene products nef, tat, rev, vpr and vpu.
Methods. Sera of HIV infected individuals from East-Africa and from West-Africa were tested for reactivity with nef, tat, rev, vpr and vpu proteins expressed in E.coli by enzyme-linked immunoassay.
Results. Nine (38%) West-African sera had reactivity to HIV-1 accessory gene products relative to 27 (93%) of the East-African sera. Antibodies to the HIV-1 nef, tat and rev gene products were significantly ($p \leq 0.002$) more often present in East-African sera compared to West-African sera. Antibodies to vpr and vpu were completely absent from all West-African sera, but also from 33% respectively 55% of the East-African sera.
Conclusion. These results render typing of the infecting HIV-strains solely based on HIV-1 accessory gene product reactivity difficult, but reactivity to vpr and vpu may add to discriminating power of type-specific serology by env peptides.

Th.C.P.36 EXPRESSION OF EIGHT HUMAN IMMUNODEFICIENCY VIRUS GENES IN ESCHERICHIA COLI FOR USE IN DIAGNOSTIC TESTS.

Devare, Sushil, Desai S., Casey J., Aneja R., Kramer D., Rupprecht K., et al. Abbott Laboratories, North Chicago, Illinois, USA.

Objective. To obtain large amounts of various HIV-1 and HIV-2 gene products using recombinant DNA technology.
Methods. Genes encoding HIV-1 gp41, endonuclease, reverse transcriptase, p17, p24, nef, HIV-2 gp41 and p24 were molecularly cloned in E.coli. In some instances genes were chemically synthesized using optimized E.coli codons to maximise expression. In order to obtain large amounts of each of the viral proteins, individual genes were expressed in E.coli using vectors with the lambda pL promoter under the control of a temperature sensitive cI repressor.
Results. Each of the eight genes was successfully expressed in E.coli. The level of expression in each case was greater than 1% of the total E.coli proteins. The HIV proteins could be readily identified in induced E.coli cultures by coomassie blue staining. The antigenicity of recombinant DNA derived proteins was demonstrated by Western blot analysis as well as sandwich enzyme linked immunoassays using sera from virus exposed individuals. Whereas, control sera showed no detectable reactivity. The availability of HIV-1 and HIV-2 proteins could be effectively used to discriminate immune response to either of the viruses.
Conclusions. The HIV-1 and HIV-2 proteins expressed in E.coli at high levels provide a safe, and efficient source to 1) detect virus infection, 2) monitor various stages of the disease and 3) discriminate HIV-1 infection from HIV-2.

Th.C.P.37 DISCRIMINATION OF HIV-2 INFECTION FROM HIV-1 INFECTION BY WESTERN BLOT AND RADIOIMMUNOPRECIPITATION ANALYSIS (RIPA).

TIMOTHY J. HOLZER, R. G. ALLEN, C. A. HEYNEN, M. M. KENNEDY, M. F. KNIGGE, D.A. PAUL, and G. J. DAWSON. Experimental Biology Research, Dept. 90D, Abbott Laboratories, North Chicago, IL 60064 USA.

OBJECTIVE : To evaluate the the use of Western blot and SDS-PAGE RIPA to confirm HIV-2 infection and to discriminate the serological response from that seen in HIV-1 infection.
METHODS : Western blot studies using HIV-1 and HIV-2 viral lysates and SDS-PAGE RIPA using ^{35}S-metabolically labelled cell lysates were used to evaluate specimens found to be repeatedly reactive in a recombinant HIV- 1/2 enzyme immunoassay. 126 specimens from the United States, Europe and Western Africa were tested. Antibody reactivity to specific viral gag, pol, and env proteins was determined. Confirmation required the detection of antibodies to both HIV-2 env and gag proteins. Discrimination required the detection of specific antibodies to env proteins of only one viral type.
RESULTS : Thirty one specimens from Western Africa and Europe were confirmed for the presence of antibodies to HIV-2 env and gag proteins. Twenty specimens had strong antibody responses to HIV-2 env proteins and weak or absent responses to HIV-1 env proteins. Low-titer cross-reactivity with HIV-1 gag (p24/26, p55) and env (gp150/160) was noted, including 8 (40%) with reactivity to gp120. Eleven HIV-2 confirmed specimens also had antibodies strongly reacting with both HIV-1 gag and env proteins suggesting dual infection. Of 95 Western blot positive U.S. specimens, variable cross-reactivity at most HIV-2 proteins was seen but with reactivity to gp120 able to discriminate all but 7 (7.4%) specimens .

Th.C.P.38 PSEUDOTYPES OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) WITH THE ENVELOPE ANTIGENS OF VESICULAR STOMATITIS VIRUS (VSV) OR HERPES SIMPLEX VIRUS (HSV)

Zhu, Z.; Chen, Steve and Huang, A..
Harvard Medical School, Boston, Massachusetts, U.S.A..

Objective. To identify the formation of pseudotypes during coinfection containing HIV genomes coated by the envelope antigens of VSV or HSV, designated HIV(VSV) or HIV(HSV), respectively.
Methods. To prepare phenotypic particles of HIV, we infected HIV RF strain-producing H9 cells with VSV temperature-sensitive (ts) O45 and thermal-labile (tl) 17 mutants or with HSV ts-J12 mutant. CD4-negative HeLa cells were used for infection with phenotypic mixtures to minimize HIV(HIV) replication. Anti-VSV or anti-HSV antiserum was used to differentiate HIV(VSV) or HIV(HSV) from HIV(HIV). HIV replication was measured by p24 production or syncytium formation on C8166 cells.
Results. Production of p24 in HeLa cells was significantly reduced when phenotypic mixtures were treated with anti-VSV. As a control, anti-VSV did not have an effect on HIV(HIV) replication in HeLa cells. The effect of anti-HSV to knock down HIV replication can be amplified by passaging anti-HSV treated particles through C8166 cells.
Conclusion. These observations indicate that pseudotypes of HIV(VSV) or HIV(HSV) can be formed during coinfection. This may be a potential mechanism for the broadening of cell tropism of HIV and for the increased spread of HIV in AIDS patients who are also infected with other viruses.

Th.C.P.39 HIV POSITIVE SERA IDENTIFIED WITH SYNTHETIC PEPTIDE ANALOGS OF ENV, GAG, TAT, AND NEF.

—McPhee, Dale*, Cumming, S.*, Kemp, B.** and Doherty, R.*
*NHMRC Special Unit for AIDS Virology. Fairfield Hospital, and
**St. Vincent's Institute, Melbourne, Victoria, Australia.

Objective: To identify synthetic peptide analogs that are specifically recognized at the earliest time point after immune recognition of infection with HIV.
Methods: Panels of known seronegative, seropositive and seroconvertor sera to HIV were screened for their reactivity to peptides derived from conserved regions of gp120, gp41, p17, tat, and nef proteins using an EIA.
Results: A peptide to the immunodominant region of gp41 was the most sensitive and specific being recognized by almost all HIV positive sera. Antibodies recognizing nef peptides were detected earlier in seroconversion to HIV than those to either a recombinant antigen based commercial EIA or the various peptides. Peptides derived from p17 were recognized by both HIV-positive and -negative sera. A tat peptide was recognized by 60% of sera, although no correlation with clinical stage of infection was apparent.
Conclusion: The results of this study determined the utility of using synthetic peptides in serodiagnosis of HIV infection. In particular antibodies to gp41 and nef proteins were recognized in peptide EIA's before reactivity was apparent with other assays.

Th.C.P.40 HIV-1 INFECTION OF HUMAN MONOCYTES IS INHIBITED BY ANTISERA TO HIV-1 OR BY LPS ACTIVATION OF THE CELLS

. Grace, S.A.; Katzenstein, David; Carrow, E.W.; Vial, P.; Webb, D.S.; and Quinnan, G.V. LRR, DV, Center for Biologics Evaluation and Research, FDA, Bethesda, MD., U.S.A.

Objective. To assess the modulating effects of HIV specific antibodies and cell activation on the infection of human monocytes by HIV-1 in vitro.
Methods. Elutriated peripheral blood monocytes from normal donors cultured for 7 days in GM-CSF/M-CSF-supplemented medium were inoculated with 1 of 5 isolates of HIV-1: IIIB; RF; 2 clinical isolates grown in lymphocytic cell lines (U455, A4BCEM); or a commercial monocytotropic strain. For studies of neutralization or enhancement, virus was preincubated with sera from normal or HIV-infected donors. To investigate the effect of monocyte activation, cells were pretreated with LPS. Productive virus infection was quantitated by p24 antigen (p24Ag) ELISA and integrated proviral DNA detected by polymerase chain reaction (PCR).
Results. Infection of monocytes was maintained with each virus isolate for 21 days. Virus infection was neutralized (complete inhibition of p24Ag production and failure to detect proviral DNA) by 4/6 HIV antibody positive (HIV Ab$^+$) sera at dilutions of 1:10 or 1:100. There was no enhancement of p24Ag production by HIV Ab$^+$ sera at dilutions from 1:10 to 1:10,000. Activation of monocytes with LPS resulted in ≥50% inhibition of p24Ag production.
Conclusions. Human monocytes maintained in GM-CSF/M-CSF-media were susceptible to infection by HIV-1 strains characterised as either lymphocytotropic or monocytotropic. Activated monocytes were resistant to infection. HIV-1 infection of monocytes was neutralised by HIV Ab$^+$ sera.

Th.C.P.41 GROWTH KINETICS OF HIV IN HTLV-1 TRANSFORMED CELLS.

Kiernan, Rosemary*; McPhee, D.*; Marshall, J.** and Doherty, R.*
*NHMRC Special Unit for AIDS Virology, **Virology Department, Fairfield Hospital, Melbourne, Victoria, Australia.

Objective: To define replication kinetics of HIV-1.
Methods: MT-2 cells were infected at an MOI of 1. Samples collected serially were then studied for reverse transcriptase activity, soluble core antigen, intra- and extra-cellular infectious virus, viral mRNA and proteins, development of CPE, and cell viability.
Results: Three clear phases of infection were observed: an eclipse phase (0-16h) in which progeny virus and CPE were not observed, an exponential phase of particle release (16-62h) coinciding with the development of early CPE, and the production of viral mRNA and proteins; and from 62-82h, extensive CPE and cell death developed, and intracellular mRNA and protein synthesis increased markedly while the amount of infectious virus released remained stable. This appeared to be associated with the accumulation of virus particles in cytoplasmic vacuoles.
Conclusion: The replication of HIV demonstrated several features typical for Retroviruses, a lengthy eclipse phase, slow accumulation of virus and low virus yields. A unique feature was the marked increase in virus-specific mRNA and proteins at the time of cell death, after peak production of infectious virus had been reached.

Th.C.P.42 MONOCLONAL ANTIBODY IDENTIFIES A CONSERVED EPITOPE OF THE HIV-1, HIV-2 AND HTLV-1 CORE PROTEINS

Liang, Chi-Ming; Henry, S. and Epstein, J.S.
Division of Blood and Blood Products, CBER, FDA, Bethesda, Maryland, USA

Objective. To evaluate the structure and function of HIV core proteins.
Methods. BALB/c mice (female, 10 weeks old) were immunized with partially purified HIV-1 proteins. Hybridomas secreting monoclonal antibodies (mAbs) against HIV-1 were produced by fusing P3X63Ag8 653 myeloma cells with the splenocytes of the immunized mice and screened by enzyme-linked immunosorbent assay (ELISA). The positive hybridomas were cloned and the mAbs were examined by ELISA and Western blot against HIV-1, HIV-2 and HTLV-1 proteins.
Results. Three mAbs against HIV-1 proteins were produced. Two of the mAbs, namely CBER-1 & CBER-2, were of IgG1 subclass; they bound to p24 core proteins of HIV-1 but not HIV-2 or HTLV-1 in Western blot. The third mAb, CBER-3, was IgG2b subclass; it recognized p24 of HIV-1 and HIV-2 on Western blot and reacted with both HIV-1 and HTLV-1 in ELISA. Comparison of the protein sequence of core proteins shows that a peptide sequence of [illegible] in HIV-1 is relatively well conserved in HIV-2 and HTLV-1. Further study showed that CBER-3 exhibited positive response in ELISA on the plate coated with the synthetic peptide, indicating that the mAb may bind to the core proteins at this conserved epitope.
Conclusion. A mAb reactive with HIV-1, HIV-2 and HTLV-1 has been produced and its likely binding epitope on the viral proteins identified. The biological activity of this conserved epitope is now under study.

Th.C.P.43 ROLE OF OLIGOSACCHARIDES ON THE PROCESSING AND MATURATION OF GLYCOPROTEINS FROM HUMAN T-CELL LYMPHOTROPIC RETROVIRUSES

Pal, Ranajit*, Hoke, G.M.*, Gallo, R.C.**, and Sarngadharan, M.G*. *Bionetics Research, Inc., Rockville, MD, **National Cancer Institute, NIH, Bethesda, MD,U.S.A.

Objective. To study the effect of oligosaccharide processing on the maturation of glycoproteins from HIV-1 and HTLV-I. Methods. Metabolically labeled viral proteins from infected cells were immunoprecipitated with specific antibodies and the immunoprecipitates were digested by endoglycosidase H. Results. The effects of deoxynojirimycin (DNM), deoxymannojirimycin (MNM) and Swainsonine on the maturation of HIV-1 glycoproteins were studied in virus-infected cells and the results are summarized below:

Inhibitor	Enzyme Target	Cleavage of gp160-gp120	Infectivity of Progeny Virus
DNM	Glucosidase I	Inhibited	Inhibited
MNM	Mannosidase I	Normal	Inhibited
Swainsonine	Mannosidase II	Normal	No effect

Treatment of HTLV-I-infected cells with MNM did not affect the maturation of gp46, although the protein had different amounts of mannose-rich oligosaccharide cores.
Conclusion. Primary trimming of mannose-rich oligosaccharide cores in HIV-1 glycoprotein is necessary for infectivity of progeny virus but the cleavage of the precursor takes place before trimming of mannose.

Th.C.P.44 MAPPING OF THE IMMUNOREACTIVE EPITOPES OF THE HIV-1 ENDONUCLEASE PROTEIN BY MEANS OF RECOMBINANT PROTEINS.

Cristina Vinga-Martins and N. Mueller-Lantzsch
Institut fuer Medizinische Mikrobiologie und Hygiene, Abt. Virologie, Klinikum der Universitaet des Saarlandes Homburg/Saar, FRG.

Objective. To define the major immunoreactive part of the HIV-1 endonuclease protein.
Methods. The complete reading frame of the endonuclease (288 AA) from HIV-1 and three subclones representing the N-terminal, central and C-terminal part of the endonuclease were cloned into the tryptophan regulated expression vector pATH. After expression four fusion proteins of 68 kD, 52 kD, 46 kD and 48 kD, respectively, were obtained and used for the production of specific polyclonal antisera (68 kD recombinant protein) or as antigens in order to map the major immunoreactive part of the HIV-1 endonuclease protein.
Results. 27 out of 27 HIV-1/endonuclease positive sera predominantly reacted with the C-terminal part of the recombinant endonuclease and only a few also showed a faint reaction against the N-terminal part in the western blot. In some cases HIV-1 positive sera which did not react against the p31 of HIV-1 infected Molt-3 cells gave a clear reaction against the C-terminus of the endonuclease.
Conclusion. The results suggest that the C-terminus contains the immunodominant epitopes of the HIV-1 endonuclease. Peptide studies for the mapping of distinct epitopes are under investigation. (Supported by the BMFT grant No. PBE/12/0318837A).

Th.C.P.45 A HUMAN MONOCLONAL ANTIBODY AGAINST ENVELOPE GLYCOPROTEIN OF HIV-1 ENHANCES HIV-1 INFECTION *IN VITRO*

W. Edward Robinson[1], Jr., D. Lake[2], D. C. Montefiori[1], Y. Masuho[3], T. Kawamura[3], W. M. Mitchell[1], and E. Hersh[2].
[1]Dept. of Pathology, Vanderbilt University, Nashville, TN 37232, USA
[2]Dept. of Medicine, Arizona Cancer Center, University of Arizona, Tucson, AZ 85719, USA.; [3]Teijin Ltd. Tokyo, Japan

Objective: To evaluate human monoclonal antibodies (HumAb) for their abilities to enhance HIV-1 infection *in vitro*.
Methods: HumAb were generated by fusion of P3x63AgU1 cells with lymph node lymphocytes from ARC patients. Protein-A purified HumAb were assayed for complement-mediated, antibody-dependent enhancement (C'-ADE) of HIV-1 infection using an MT-2 cell microtiter infection assay.
Results: One HumAb, V10-9, of seven tested was found to mediate C'-ADE of HIV-1 infection *in vitro*. This IgG1κ recognized gp160, gp120, and gp41 on western blot and enhanced HIV-1 infection to a dilution of >1:17,468 (28 ng/ml). Enhanced infections were characterized by accelerated appearance of HIV-induced cytopathic effect, increased antigen synthesis, increased reverse transcriptase release, and increased progeny virus production. This HumAb did not neutralize HIV-1 in the presence or absence of complement.
Conclusion: The generation of a HumAb that enhances HIV-1 infection but fails to neutralize HIV indicates that at least some neutralizing and enhancing antibodies recognize different epitopes.

Th.C.P.46 CORRELATION STUDY INVOLVING THE DETECTION OF HIV-1 IN SAMPLES FROM AIDS PATIENTS USING CO-CULTURE, p24 ELISA, AND TAS- AND PCR-MEDIATED HYBRIDIZATION ASSAYS

Gingeras, Thomas*; Guatelli, J.**; Richman, D.**; and Davis, G.*; et al.
*The Salk Institute Biotechnology/Industrial Associates, Inc. (SIBIA), La Jolla, California 92037, USA. **Depts. of Medicine and Pathology, UCSD School of Medicine, San Diego, California 92161, USA.

Objective. Correlation study involving the detection of HIV-1 in samples from AIDS patients using co-culture, p24 ELISA, and TAS (transcription-based amplification system)- and PCR (polymerase chain reaction)-mediated hybridization assays.
Methods. A collection of peripheral blood lymphocyte samples which were characterized as: 1) "+" for both co-culture and p24 assays; 2) "-" for both co-culture and p24 assays; 3) "+" for co-culture and "-" for p24 assays; or 4) "+" for p24 and "-" for co-culture assays was studied for the presence of HIV-1 nucleic acid sequences using TAS- and PCR-mediated hybridization assays. After TAS or PCR amplification, detection of amplified products was carried out by a variety of methods, including bead-based sandwich hybridization, Northern and Southern blot hybridizations, and solution hybridization.
Results and Conclusion. These experiments have permitted: 1) the results derived from immunological and culture-based assays to be compared to the results derived from amplification-mediated hybridization experiments; and 2) the comparison of PCR- and TAS-mediated hybridization results. Amplification-mediated hybridization assay results derived from individual patients indicate increasing viral nucleic acid concentrations with time, whereas other assay results (p24 and co-culture) appear more variable.

Th.C.P.47 EXPANDED HOST RANGE OF HIV ACQUIRED THROUGH MODIFICATION OF GP120

Seto, Deborah, Levy, J.A., Cheng-Mayer, C.
Cancer Research Institute, University of California, San Francisco, CA, USA

Objective: To determine what factors control the cellular tropism of HIV.
Methods: The host range of HIV obtained by passage through different cell types was determined by infectivity studies. Genomic variations of HIV recovered were assayed by Southern blot analyses and modification of gp120 examined by glycosidase treatment.
Results: HIV-1 isolates passaged through HUT-78 cells vs. peripheral blood mononuclear cells (PMC) acquired an expanded host range and replicated better in HUT-78 than the virus from PMC (Table). Restriction analyses showed that the same virus is present in the different cell types. Furthermore, passage of the virus produced from HUT-78 back through PMC results in HIV with host range properties of the HIV recovered from PMC. Studies using castanospermine and endoglycosidases indicate that the change in cell tropism of HIV-1 could be related to modification in the gp120.

		Replication in						Plaque	
HIV-SF	Source	PMC	HUT	[illegible]	Jur	CEM	U937	Formation	Cytopathology
73	PMC	+	-	-	-	-	-	-	-
73	HUT78	+	+	+	-	-	-	-	+
663	PMC	+	+	+	-	-	-	-	++
663	HUT78	+	+	+	+	+	+	+	+++

Conclusion: Glycosylation of gp120 may contribute to the heterogeneity of host cell tropism, suggesting that interfering with glycosylation might prevent infection and spread of HIV.

Th.C.P.48 REPLICATION OF HIV-1 IN A VARIETY OF ANIMAL FIBROBLAST CELLS USING PHENOTYPICALLY MIXED VIRAL PARTICLES

Canivet, Marine; Hoffman, A.; Hardy, D.; Semalinger, J. and Levy, J.A.
Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To determine whether the inability of HIV to infect animal cells can be abrogated by enveloping the virus in a xenotropic (X-MuLV) or polytropic (HIX) mouse retrovirus coat, and to study variations in intracellular control of HIV replication.
Methods: Phenotypically mixed particles were obtained by superinfecting X-MULV or HIX-chronically infected HUT-78 cell lines with HIV_{SF33}. The progeny virions were inoculated onto a variety of HIV-resistant animal fibroblast and epithelial cells. Their ability to replicate was assayed by reverse transcriptase activity using both Mn^{++} and Mg^{++} divalent cations, by detection of the MuLV p30 or HIVp25 antigens (IFA and ELISA tests), the mink S^+L^- assay and Western blot techniques.
Results: HIV can be enveloped in an MuLV coat and productively infect a wide variety of animal cell types. Differences in level of HIV replication in various cells were observed.
Conclusion: The major block of HIV infection occurs at the cell surface, but an intracellular regulation of the virus can also be present. Phenotypically mixed viruses may be useful for developing an animal model system for AIDS.

Th.C.P.49 THE ANTIBODY RESPONSE TO HUMAN IMMUNODEFICIENCY VIRUS: NEUTRALIZATION VS ENHANCEMENT.

Homsy, Jacques; Meyer, M. ; Cheng-Mayer, C. and Levy J.A. , Cancer Research Institute, School of Medicine, University of California, San Francisco, CA, U.S.A.

Objective: To examine whether antibody-dependent enhancement of HIV infectivity could explain the apparent lack of protection conferred by neutralizing antibodies in vivo, and examine whether the appearance of enhancing antibodies is associated with progression towards AIDS.
Methods: The sera of 17 HIV-infected individuals comprising asymptomatic, ARC and AIDS patients were tested for neutralization and enhancement against the patients' own (homotypic) HIV isolates as well as against HIV$_{SF33}$, an established strain which exhibits cytopathicity and a wide host range. Five patients' isolates were also tested for homotypic neutralization/enhancement in macrophages. Moreover, sequential sera of an asymptomatic, an ARC and an AIDS patient obtained over a three-year period were tested against homotypic isolates obtained at the same time points.
Results: While all sera neutralized HIV$_{SF33}$, only one had such effect on the homotypic isolate, and one asymptomatic, two ARC and four AIDS patients' sera enhanced their own isolates. In macrophages, four out of five patients' sera (comprising one asymptomatic and 3 AIDS patients) enhanced their own isolates. Finally, the sequential study showed that the asymptomatic patient's early and late sera neutralized both early and late homotypic isolates, the ARC patient's early and late sera enhanced his early but not his late HIV isolate and that the AIDS patient's late serum enhanced his late isolate, while both his early and late sera neutralized his early isolate.
Conclusion: These results suggest that enhancing antibodies might be an indicator of disease progression and underline the need to examine larger groups of infected individuals to assess for such association.

Th.C.P.50 ARE THERE MULTIPLE STRAINS OF HIV IN AN INFECTED INDIVIDUAL?

Pan, L.Z.; Cheng-Mayer, C. and Levy, J.A.
Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To determine whether more than one genomically distinct HIV-1 strain can be recovered from an infected individual.
Methods: Culture the peripheral blood mononuclear cells from a clinically healthy individual who has had more than four hundred sexual partners in a life time. Cocultivate these cells with ten different cell lines. Obtain HIV isolates with tropism for different cell types including established T and B cell lines, peripheral blood macrophages, CD4+ lymphocytes and human fibroblasts. Biologically clone each HIV isolate in the cell lines selected. Evaluate the biologic, serologic and molecular properties of the various isolates by cellular host range, cytopathic effects, plaque assays and restriction enzyme analyses.
Results: Ten different HIV-1 isolates were obtained by the above techniques from one individual. All were found to grow to high titer in macrophages and only infected the Sup T and HK B cell lines. None of them formed plaques in the MT4 cell line. No virus isolate infected HUT-78, Jurkat, CEM , U937 or the MT B cell lines. No difference in neutralization pattern among the isolates was observed.
Conclusion: All ten virus isolates showed similar biologic and serologic properties. Their molecular properties are under study. The results suggest that this healthy individual is infected with one strain of HIV-1. By its substantial growth in peripheral macrophages, this HIV resembles virus isolates from individuals with neurologic disease. Similar studies now in progress on other infected individuals may reveal the presence of more than one distinct HIV-1 strain.

Th.C.P.51 PARAMETERS INVOLVED IN THE CELL FUSION INDUCED BY THE HUMAN IMMUNODEFICIENCY VIRUS

Tang, Shan-Bei and Levy, J.A. Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To define the parameters involved in HIV-induced fusion.
Methods: Syncytium formation was measured by cell co-culture of the fusion-sensitive Sup T cell line with HIV$_{SF33}$ chronically infected Jurkat cells. The detection of lymphocyte markers on cells was conducted by FACS analysis. Nucleic acid synthesis and protein synthesis were measured by ^{3}H-labelled thymidine or uridine and ^{3}H-labelled leucine incorporation. HIV viral proteins were analyzed by immunoblot analysis.
Results: Optimal cell fusion was observed when chronically infected cells and uninfected cells were used at 1:1 to 1:4 ratios. All the T and B cell lines expressing the CD4 protein fused with the HIV infected cell line except the CEM line despite the fact that it had a 98% expression of the CD4 antigen. Cell clumping and cell fusion were markedly inhibited by D-glucose, D-mannose, D-galactose at 0.5 M and dextran sulfate at 10 uM. Con A, but not PHA, was capable of blocking cell fusion. An inhibitor of glycosylation, tunicamycin (0.1 ug/ml), inhibited cell fusion in HIV acute infection and cell to cell fusion. Treatment of uninfected or the infected cells with the metabolic inhibitors, cycloheximide, mitomycin-C and aphidicolin did not affect the efficiency of cell fusion. The proteolytic enzymes, trypsin and alpha-chymotrypsin, efficiently prevented cell fusion in HIV acute infection and cell to cell fusion. Subsequent FACS analysis on the Sup T cells treated with trypsin indicated that the CD4 protein had not been removed from the cell surface.
Conclusion: HIV induced cell fusion depends on HIV gp120, the expression of the CD4 protein on the surface of uninfected cells, and the presence of sugar moieties particularly D-mannose. Protein and nucleic acid syntheses are not required for the fusion process. The ability to block fusion with trypsin without removing the CD4 protein suggests a receptor besides CD4 is required for the fusion event.

Th.C.P.52 GROWTH OF HIV-1 AND T CELL SUBSETS IN SEQUENTIAL BLOOD SAMPLES TAKEN FROM A HHV-6 PATIENT BEFORE, DURING, AND AFTER INFECTION

Feorino, Paul; Warfield, D.; and Sanderlin, K. Centers for Disease Control, Atlanta, GA, USA.

Objective. To evaluate the growth of HIV-1 and the T cell subsets of sequential blood samples taken before, during, and after HHV-6 infections.
Method. T lymphocytes from sequential blood samples were:
1) Inoculated with varying doses of HIV-1 and measured for virus growth by reverse transcriptase and HIV-1 antigen assay testing;
2) Measured for T subset contents by flow-cytometry.
Results. Cells taken before and after illness were normal in HIV-1 growth potential and in total T, CD4 and CD8 parameters. Samples taken during infection indicated over 70% loss of ability to be infected with HIV-1, about 35% loss of total T, about 45% loss of CD4, and about 20% loss of CD8. These results also correlated with the presence of HHV-6 antibody and virus. Antibody in the pre-infection samples was 1:10, converted to 1:320 during infection, and by eight months post infection was 1:20. HHV-6 virus was seen only in the two specimens, four weeks apart, showing T cell depletion.
Conclusion. During this HHV-6 infection, CD4 cell counts and the ability of the patient's lymphocytes to be infected with HIV-1 are both drastically reduced. Both parameters return to normal soon after illness.

Th.C.P.53 GOLD-LINKED IMMUNO ASSAY (GLIA) : A METHOD IN VIRAL DIAGNOSIS

Grewe, Carola and Gelderblom, H.R.
Robert Koch-Institute of the Federal Health Administration, Berlin,
FEDERAL REPUBLIQUE OF GERMANY

Objective. To describe a simple, rapid and cheap method in viral diagnosis (i.e. HIV) allowing to identify antibodies in patient sera as well as viral antigens in tissue biopsies.
Method. Infected suspension culture cells are adsorbed to glass slides coated with Poly -L-lysine or microtiter plates coated with alcian blue and fixed mildly. A drop of patient serum is placed on the cell layer. After incubation the serum is washed off and a drop of goat anti-human immunogold conjugate is placed on the cells. After incubation and washing the colloidal gold undergoes silver enhancement and light microscopic evaluation.
Results. The silver enhanced gold colloids lead to a specific gold-brown or black, granular staining of virus producing cells or purified virus incubated with serum containing specific antibodies. Likewise, semithin cryocuts attached to a glass slide are covered with an antiviral antibody and subsequently treated with immunogold labeling and silver enhancement. The possibilities and limitations of the method in comparison to well established techniques are discussed.
Conclusion. The gold linked immuno assay is a simple and rapid method for screening probes (i.e. sera and tissue biopsies) from patients at risk of infection with HIV or other viruses. The method was presented in a lecture, University of Freiburg, 1988.
Manuscript in preparation (J. Virol. Methods).

Th.C.P.54 CHARACTERIZATION OF PROTEINS ASSOCIATED WITH TWO NOVEL RETROVIRUSES ISOLATED FROM AIDS-ASSOCIATED LYMPHOMA TISSUE.

Ng, Valerie L., Khayam-Bashi F, Marsh J, and McGrath MS.
University of California, San Francisco, and San Francisco General Hospital, San Francisco, California, USA.

Objective: To characterize the proteins associated with two retroviruses isolated from primary AIDS-associated lymphoma tissue.
Methods: Non-equilibrium two-dimensional SDS-PAGE, limited Staphylococcal V8 protease digestion, exhaustive tryptic peptide fingerprinting.
Results: We purified 2F7 and 10C9 virus particles from culture supernatants by sucrose density equilibrium gradient centrifugation, and analyzed the proteins associated with the purified virions. Non-equilibrium two-dimensional SDS-PAGE analysis of radioiodinated 2F7 and 10C9 viral proteins demonstrated prominent 27kd and 14kd species, which comigrated with similarly sized proteins present in bovine leukosis virus (BLV). The 27 kd proteins (p27s) demonstrated peptide homology (by limited Staphylococcus V8 protease digestion and by exhaustive tryptic peptide fingerprinting) with the p24s of BLV, HTLV-I and HTLV-II, but did not with the p24 of HIV-1.
Conclusion: These data support the inclusion of these two retroviruses in the subfamily of oncoviruses.

Th.C.P.55 DIAGNOSIS OF HIV-2 OR HIV-1/HIV-2 DOUBLE INFECTION WITH SYNTHETIC PEPTIDES AS AN ADDITIONAL CONFIRMATORY ASSAY

Van Der Poel, Cees*; Lelie, N.**; Reesink,H.*; Cot, M.***, Huisman, H.**
* Red Cross Blood Bank, Amsterdam, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.
*** Diagnostics Pasteur, Marnes-la Coquette, France.

Objective. To discriminate between HIV-1/HIV-2 infection of serum samples with reactivity to both HIV-1 and HIV-2 envelope glycoproteins in WB.

Methods. Synthetic peptides of the transmembrane glycoprotein (peptide "39" for HIV-1 and peptide "41.2.1" for HIV-2) were used in a spot test immuno assay (Pepti-LAV 1-2, Pasteur) and further in two separate ELISA's, employing these peptides on the solid phase. Four serum samples, reactive to both HIV-1 and HIV-2 glycoproteins in WB, were tested with Pepti-Lav, and with the peptide ELISA's in serial dilutions, and after pre-absorbtion with homologous and heterologous soluble synthetic peptide.

Results. Three of 4 samples were clearly HIV-1. One sample showed a higher reactivity to "41.2.1" in Pepti-Lav and also in serial dilution with ELISA. Pre-absorbtion of this sample with increasing concentrations of soluble homologous and heterologous peptides, excluded cross-reactivity.

Conclusions. Double reactivity to HIV-1/HIV-2 in WB, may not be due to crossreactivity. The results suggest an HIV strain with epitopes of both HIV types or HIV-1/HIV-2 double infection.

Th.C.P.56 SUPERINFECTION WITH INFECTIOUS HIV-1 OF DEFECTIVE HIV-1 PRODUCING CELL CLONES

Ikuta, Kazuyoshi*; Yunoki, M.*; Imai, H.*; Miyake, S.*; Hirai, K.** and Kato, S.*.
*Research Institute for Microbial Diseases, Osaka University, Suita, Osaka,
**Tokai University School of Medicine, Isehara, Kanagawa, Japan.

Objective. To examine the possibility of superinfection with infectious HIV-1 of the cell clones producing defective particles.
Methods. Cell clones producing defective HIV-1 were isolated by limiting dilutions of the MT-4 cells, which survived the HIV-1 infection after drastic cell lysis, or of MOLT-4 cells adsorbed with HIV-1 for 1 hr. The cell clones were superinfected with infectious HIV-1 and passaged as continuous cell cultures, and then recloned. The cell clones were biochemically and molecular-biologically characterized.
Results. All cell clones examined did not show cytopathic effect by the superinfection, and became the producers of infectious HIV-1. The structures of proviral DNA in the superinfected cells, which had apparent deletions before the superinfection, were mostly those of intact HIV-1 DNA. However, the HIV-1 phenotypes (at least env gp120 and gag p18 proteins) of the superinfected cells showed those of the cell clones before the superinfection.
Conclusion. Cells primarily infected with HIV-1 containing defective genome survived the HIV-1 infection and become the persistently infected cells. However, these survived cells could be changed to the producers of infectious HIV-1 by the following superinfection without cytolysis. The production of infectious HIV-1 might be due to the recombination between defective proviral DNA and superinfected viral DNA.

Th.C.P.57 ASSOCIATION OF HUMAN HERPES VIRUS 6 (HHV6) AND HIV INFECTIONS IN AFRICA

Scott, Daniel A. and Constantine, N.T.
U.S. Naval Medical Research Unit No.3, Cairo, Egypt, (A WHO collaborating center for AIDS)

Objective. To assess the prevalence of antibody to HHV6 in HIV infected patients versus uninfected controls.
Methods. A total of 66 HIV positive sera (65 HIV-1 and 1 HIV-2) and 66 age and sex match controls, collected as part of an ongoing HIV screening program between Jan 1987 and Jan 1989, were assayed for antibodies to HHV6 by an immunofluorescence assay (Pan Data Systems Inc., Rockville, MD).
Results. The HIV positives included 55 males and 11 females with a mean age of 27.0 ± 9.9 years. The subjects resided in 14 different African countries. Infections were presumed to have been acquired in their home of record as well as Europe and the United States. The serologic results are presented in the table. We considered a titer of ≤40 as negative and ≥160 as positive with 80 being indeterminant. Twenty-three percent (15/66) of the HIV positive sera were positive for HHV6 versus 8% (5/66) of the HIV negatives; this was a significant difference (p=.0287).

Antibody	Number	
Titer	HIV +ve	HIV -ve
Negative	14	29
20	16	11
40	20	20
80	1	1
160	1	3
>160	8	2

Conclusion. In this diverse group of HIV infected subjects from throughout Africa we found a significant association between HIV and HHV6 infection.

Supported by NAVMEDRSCHDEVCOM, Bethesda, MD Work Unit No. 3M463105H29.AA.335.

Th.C.P.58 SIVsmm, A POSSIBLE PROGENITOR OF HIV-2 AND SIVmac

Li, Yen; Naidu, Y.M.; Kestler, H.W.; Fultz, P. ; Daniel, M.D.; and Desrosiers, R.C.
New England Regional Primate Research Center, Harvard Medical School, Southborough, MA and Yerkes Regional Primate Research Center, Emory University, Atlanta, GA, USA.

Objective. To study the relationships among primate lentiviruses and the origin of human and monkey AIDS viruses.
Methods. Viral DNA was molecularly cloned from chronically infected cells, using standard recombinant DNA methodology. Nucleotide sequences were determined by oligonucleotide directed dideoxyribonucleotide chain termination method of Sanger et al.
Results. Amino Acid Identities over a 1000 nucleotide region in pol.

	SIVsmm7	SIVmac142	HIV-2rod	SIVagmTyo1
SIVmac142	84			
HIV-2rod	75	84		
SIVagmTyo1	56	59	61	
HIV-1$_{HXB2}$	56	57	60	60

Conclusion. SIVsmm7, SIVmac, and HIV-2 form one closely related subgroup of primate lentiviruses. It provides preliminary evidence for SIVsmm being a source for cross-species transmission for the origin of HIV-2 in humans and of SIVmac in captive macaque colonies.

Th.C.P.59 MAPPING OF SEVEN HIV1 ANTI-P24 MONOCLONALS USING A SERIES OF OVERLAPPING PEPTIDES

Ferns, R. Bridget* Partridge, J.C.* Tedder, R.S.* Spence, R.P.**
* University College and Middlesex School of Medicine, London, UK.
** Wellcome Biotech, Beckenham, Kent, UK.

Objective. To locate the epitopes of 7 characterised anti-p24 monoclonal antibodies for the assessment of putative HIV p24 sequence variation.
Method. A series of 15mers (obtained from P.Lachmann through MRC ADP), which overlapped by 5 aminoacids (aa) across the p24 of HIV1SF2 were coated onto the solid phase. The binding of supernatant fluid from the 7 monoclonals raised against HIV1CBL1 was detected by an anti-mouse conjugate.
Results. Five epitopes for the antibodies were positively identified:

NAME	LOCATION ON HIVBRU (aa)
DF9C3	132-147 and 194-197 HisGluAla
1D8F6	147-152
3D3	177-182
EH12E1	204-217
EB1A9	256-267

Only EH12E1 cross reacted in immunofluoresence (IF) with HIV2ROD and other unpublished HIV2 isolates. Aa 204-217 are similar between HIVBRU and HIV2ROD. The sixth and seventh, CD12B4 and 1E8G2 failed to react with the SF2 peptides. Other data generated using mutants from recombinant p24 showed these monoclonals to react near the C terminus. CD12B4 reacted in IF with HIVBRU (312 Glu) but not HIVSF2 (312Asp) indicating 309-316 as a possible CD12B4 epitope.
Conclusion. Six possibly 7 epitopes have been mapped with murine monoclonal antibodies. One antibody identified a conformational epitope which by IF and predicted sequences was conserved between HIV1 and HIV2ROD.

Th.C.P.60 LECTIN BINDING PATTERN OF HIV ENVELOPE GLYCOPROTEIN

Hansen, John-Erik S.*; Nielsen,C.M.**; Nielsen, C.**; Heegaard,P***; Mathiesen,L.*; Nielsen, J.*.
*Department of Infectious Diseases, Hvidovre Hospital, Denmark,
**State Serum Institute, Copenhagen, Denmark, ***The Protein Laboratory, University of Copenhagen, Denmark.

Objective. To characterize the oligosaccharides of the envelope glycoprotein, gp120, of different HIV isolates.
Methods. Gp120 from HTLV III B, CDC isolate 451 and LAV-2 was immobilized on nitrocellulose paper and incubated with thirteen different peroxidase conjugated lectins.
Results. Identical lectin binding was found in all three isolates: Concanavalin A, Wheat germ agglutinin, Lens culinaris agglutinin, Vicia faba agglutinin, Pisum sativum agglutinin and Phytohaem(erytro)agglutinin all bound to the envelope glycoprotein. None of the other lectins, which mainly had affinity to O-linked glycans, bound to the envelope glycoprotein.
Conclusion. From the known affinity of the various lectins to oligosaccharides it is proposed that at least four different types of N-linked glycans exist on gp120: a high mannose type (Con A), a bisected hybrid type (WGA), a biantennary fucosylated complex type (LCA, VFA, PSA) and a triantennary bisected complex type (PHA-E). Each gp120 molecule has both high mannose type glycans and sialylated (hybrid and/or complex) glycans.

Th.C.P.61 INHIBITION OF SYNCYTIUM FORMATION WITH LECTINS

Hansen, John-Erik S.*; Nielsen, C.M.**; Nielsen, C.**; Heegaard, P.***; Mathiesen, L.*; Nielsen, J.*.
*Department of Infectious Diseases, Hvidovre Hospital, Denmark, **State Serum Institute, Copenhagen, Denmark, ***The Protein Laboratory, University of Copenhagen, Denmark.

Objective. To examine the involvement of the glycans of gp120 in binding to the CD4 receptor.
Methods. Ten different lectins were added to HTLV III B infected H9 cells prior to coculture with CEM cells. Incubations were performed in RPMI 1640 with or without competing monosaccharides. Multinucleated giant cells, syncytia, were counted after 4 and 24 hours using phase-contrast microscopy.
Results. The lectins Concanavalin A, Wheat germ agglutinin, Lens culinaris agglutinin and Phytohaem(erytro)agglutinin blocked or inhibited formation of syncytia. This inhibition was reversible with competing monosaccharides. Lectins acted on HIV-infected cells, not on uninfected cells. Lectins with no effect on syncytium formation were: PHA-L, GSA-1, GSA-2, UEA-1, HPA, SBA and PNA.
Conclusion. Lectins which bind to either of the four different glycans of gp120 interfere with CD4-gp120 binding as evaluated by formation of syncytia.

Th.C.P.62 ELECTRON MICROSCOPIC EVIDENCE FOR COINFECTION AND REPLICATION OF HERPESVIRUS AND HIV-1 IN THE SAME HUMAN T-CELL

Kucera, L.; Leake, E.; Raben, David; Iyer, N.; Myrvik, Q.
Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC, 27103, USA.

Recent data from our laboratory indicated that unstimulated human leukemia cells (MT-4, Molt-4, CEM-SS) are permissive for both herpes simplex virus type 2 (HSV-2) and human immunodeficiency virus type 1 (HIV-1). Published evidence (Gendelman et al., P.N.A.S. (USA) 83:9759, 1986) indicates that HSV-2 can transactivate HIV-1 long terminal repeat-directed bacterial CAT gene expression. Objective. We studied the potential interaction of HSV-2 and HIV-1 virions. Methods. At various times after infection with HIV-1 alone or HIV-1 + HSV-2 we harvested CEM-SS cells for analysis by transmission electron microscopy (TEM) and HIV-1 p24 core antigen synthesis by ELISA. Results indicated budding of HIV-1 particles through the plasma membrane of cells infected with HIV-1 alone or in combination with HSV-2 at 8 days post infection. Also, we observed HIV-1 particles budding into HSV-2 containing cytoplasmic vacuoles. At 10 days after HSV-2 coinfection HIV-1 p24 core antigen synthesis was stimulated 8-fold compared to HIV-1 infected cell control. In contrast, HIV-1 did not affect HSV-2 replication in the coinfected cells. Conclusion. These data provide the first evidence that HSV-2 and HIV-1 can coinfect and simultaneously replicate in the same human T-cell and that HSV-2 may serve as a cofactor in activation of latent HIV-1 infections.

Th.C.P.63 CO-INFECTION OF A HUMAN T-LYMPHOCYTE CELL LINE WITH HIV-1 AND A NEWLY IDENTIFIED VIRUS-LIKE INFECTIOUS AGENT (VLIA).

Wong, Dennis M; Benish, JB and Lo, S-C. American Registry of Pathology, Dept. of Infectious and Parasitic Diseases, Armed Forces Institute of Pathology, Washington, D.C., USA

Objective. To determine the effects of the VLIA (J Trop Med Hyg, Feb. 1989) on HIV-1 infection of A.301, a CD4 positive T-cell line.
Methods. A.301 cells were infected with HIV-1 (LAV strain) or VLIA or both agents simultaneously. At various times after infection, supernatant samples were harvested from all cultures and assayed for reverse transcriptase (RT) activity, HIV antigen, VLIA antigen and HIV infectious titer.
Results. Infection by HIV-1 resulted in the production of HIV antigen, RT and the development of large syncytial cells associated with cell death. RT activity was high during the peak of infection, as was the level of antigen, as determined by the antigen capture assay. In contrast, cultures co-infected with both HIV-1 and VLIA demonstrated little syncytial formation, yet cytopathogenesis was present, resulting in a sharp decrease in viability. Although little or no RT activity was detected in the culture supernatants, replication of HIV-1 occurred during co-infection because the HIV antigen level and infectious titer in the supernatants tested were comparable to samples obtained from cultures infected with HIV-1 alone.
Conclusions. (1) During co-infection, despite the fact that VLIA suppressed the syncytia, cell death occurred. (2) Infectious HIV was produced in the co-infected cultures. (3) Co-infection with VLIA masked the identification of RT activity in cultures produced by HIV infection.

Th.C.P.64 CHEMICAL INDUCERS OF CELL DIFFERENTIATION INHIBIT HIV REPLICATION IN VITRO

Viza, Dimitri*; Aranda-Anzaldo, A.*, Ablashi, D.**; Salahuddin, S.Z.*** and Vich, J.****
*Faculté de Médecine, 75006 Paris, France, **N.I.H. / N.C.I., Laboratory of Cellular and Molecular Biology, Bethesda, Maryland, U.S.A., ***N.I.H. / N.C.I., Laboratory of Tumor Cell Biology, Bethesda, Maryland, U.S.A., ****L.P.L. Laboratories, Barcelona, Spain

Objective. Investigate the effect of Chemical Inducers of Cell Differentiation (CICD) on HIV-infected cells.
Methods. Four chemicals known to induce cell differentiation changes in vitro - dimethylsulphoxide, dimethylformamide, pyridine-N-oxide and butyric acid - were used for the incubation of two lymphoblastoid cell lines - LDV/7 and MOLT 4 - infected with HIV. Their effect was assessed by evaluating the amounts of p24 and RT activity in the Tissue Culture Medium (TCM).
Results. The four compounds used to pre-incubate the lymphoblastoid cells tested failed to prevent viral infection and they also failed to inactivate the virus in vitro. In contrast, they did inhibit viral replication within the infected cells. The observed effect is dose-dependent and transient, viral replication resumes after the removal of the compounds from the TCM. The infected cells in presence of CICD express p24 antigens on their cell surface despite the inhibition of viral replication.
Conclusion. CICD have a virustatic effect on HIV-infected cells in vitro. Further studies investigating the in vivo activity are thus warranted.

Th.C.P.65 Brain and Blood HIV-1 Isolates from the Same Individual have Different Biological Properties

Weiss, Carol D.; Cheng-Mayer C., Seto, D.; Levy, JA.
Cancer Research Institute, University of California, San Francisco, CA 94143 USA

OBJECTIVES: To determine whether virus isolates from the brain and blood of the same individual have different biological properties, and are genetically related.

METHODS: Brain and blood specimens, collected from 6 AIDS patients with neurological abnormalities, were co-cultivated with PHA-stimulated normal PBMC. Virus isolates were tested for their ability to grow in established T-cell lines (HUT-78, CEM, Jurkat, U937, Sup T) and in primary macrophages. Neutralization assays were performed using autologous and/or heterologous antisera. Genetic relatedness was assessed by restriction enzyme digests and Southern blot analysis.

RESULTS:

Brain/blood pairs:	#1A/B	#2A/B	#3A/B	#4A/B	#5A/B	#6A/B
T-cell lines:	-/+	-/+	-/+	-/++	+/-	+/-
Macrophages:	+++/-	+/-	+/-	+++/-	++/-	++/-

No isolates were significantly neutralized. Restriction enzyme fragment patterns of 5/5 pairs were similar but not identical.

CONCLUSIONS: Brain and blood HIV-1 isolates from the same individual are variants of each other and frequently have different cellular tropisms. This finding suggests that genetic changes in HIV-1 that occur within individuals are clinically important because they can lead to variants that can infect and cause pathological effects in different tissues.

Th.C.P.66 INHIBITION OF THE MATURATION OF HIV STRUCTURAL PROTEINS BY A RENIN PEPTIDE INHIBITOR

MARCHETTO S.(1), NISATO D.(2) and CHERMANN J.C.(1)

(1) Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cédex 9 - FRANCE.
(2) SANOFI Recherche - Centre de Montpellier - Rue du Pr. J. Blayac - 34082 MONTPELLIER Cédex - FRANCE.

The protease encoded by the Human Immunodeficiency Virus (HIV) pol gene, cleaves the gag-pol protein precursors and plays an important role in the viral replication cycle of HIV.
The HIV protease belongs to the family of aspartyl-proteases, as pepsin or renin, and can be inhibited by specific inhibitors.
Fourteen synthetic peptides known to be inhibitors of renin, were tested, one of them showed an inhibition of the cytopathic effect of HIV on MT4 cells.
This peptide also inhibited viral production by the CEM cell line, since no reverse transcriptase activity was detected and no viral antigen was revealed by immunofluorescence during several weeks after infection by HIV.
Nevertheless, when the inhibitor peptide was removed from the culture, infectious virus particles were produced after a few days.
These results demonstrate that specific inhibitors of proteases can block "in vitro" infections by HIV and provide possible strategies against AIDS.

Th.C.P.67 HIV DOWN-REGULATES ITS CD4 RECEPTOR BY TWO DIFFERENT MECHANISMS.

Salmon P*, Olivier R**, Rivière Y**, Montagnier L**, Gluckman JC*, Klatzmann D*.
*Hôpital Pitié-Salpêtrière, Institut Pasteur, Paris ; **Transgène, Strasbourg, France.

Using mAbs and a genomic probe to the CD4 molecule, the HIV receptor, we demonstrated that HIV replication induced the disappearance of its functional receptor from the cell surface by two distinct mechanisms. First, after being expressed onto the cell surface, HIV envelope gp110 complexed CD4, efficiently masking the CD4 epitope used by the virus to bind its receptor. This phenomenon occured on the surface of each infected cell and was not due to the release of soluble gp110 ; infection with recombinant HIV/vaccinia viruses expressing a mutated HIV env gene designed to prevent gp110 release from the cell surface induced a similar gp/CD4 complexes formation. Second, virus replication induced a dramatic and rapid loss of CD4 mRNA transcripts, preventing new CD4 molecules from being synthesized. One possible explanation of this phenomenon could be the negative regulation of CD4 transcription by HIV replication. An expression vector containing a reporter gene under the control of a ~ 2Kb genomic sequence upstream to the CD4 gene transcription start, which includes the putative CD4 gene promoter, has been constructed to test this hypothesis. Modulation of the reporter gene expression after transfection of this construct together with various HIV genes expression vectors are currently being analyzed. The possible down-modulation of CD4 expression by HIV is reminiscent of a phenomenon which occurs during T-cell maturation and may provide new approaches to the study of T-cell ontogeny. Understanding the down-modulation of CD4 by HIV may provide new insights in understanding the molecular mechanisms of viral interferences.

Th.C.P.69 QUANTIFICATION AND CELLULAR DISTRIBUTION OF HIV PROVIRAL DNA IN BUFFY COATS FROM HIV-SEROPOSITIVE HAEMOPHILIACS

Simmonds, Peter*; Peutherer, J.F.*; Leigh-Brown, A.J.*; Bishop, J.O.* and Ludlam, C.A.**.
*University of Edinburgh, **Royal Infirmary, Edinburgh, Scotland, UNITED KINGDOM

A PCR method has been developed that detects individual molecules of HIV DNA in several micrograms of cellular DNA. This has allowed an analysis of the quantity and cellular distribution of HIV-specific DNA in buffy coat samples from seropositive haemophiliac patients. Serial dilutions of DNA prepared from buffy coat cells were tested by the PCR and the number of copies of HIV DNA measured. This figure was compared with the proportion of cells containing HIV DNA, obtained by a titration of the buffy coat cells themselves prior to DNA extraction. To corroborate these data, the number of HIV DNA molecules in each of the isolated single cells could be determined by further dilution and retesting of the DNA prepared from each. Results have shown that relatively few buffy coat cells contain HIV-specific DNA, although this is variable between patients and those cells that are positive have a relatively high copy number. Prior cell separation allows a similar analysis to be made on different cell types. Finally, primers spanning the junction on circularisation of HIV DNA in the cell can be used to show the configuration of the individual HIV DNA molecules found within each cell.

Th.C.P.71 SEQUENCE ANALYSIS OF A HIGHLY CYTOPATHIC STRAIN OF HIV1 : CORRELATION BETWEEN BIOLOGICAL AND GENOMIC VARIABILITY

SPIRE B., SIRE J., NEUVEUT C. and CHERMANN J.C.

Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cédex 9, FRANCE

A highly cytopathic strain of HIV1 named HIV-NDK has been isolated from a Zairian patient with AIDS : this isolate is 10^5 times more cytopathic and more infectious than the prototype. In order to correlate the high cytopathic properties of this strain with relevant genetic variations we have cloned and sequenced the 9143 nucleotides of this isolate and compared the deduced amino acid sequence with those of other isolates.
The principal feature which could be drawned from the time analysis of the HIV-NDK sequence is that variability is not clustered in one particular region but rather spread out all along the genome. The maximum of variability was as expected in the external glycoprotein gp120. Hypervariable stretches were detected at the same positions as for other isolates. The region responsible for the binding with the CD4 molecule was highly conserved, but participation of the hypervariable regions to a modification of the CD4 - gp120 interaction could not be excluded. Futhermore a small deletion of three amino acids was identified in the C-terminal part of the P18 nucleocapside protein which could be involved in the cytopathic effect. Alignment of the viral regulatory proteins of HIV-NDK and other HIV1 variants did not show any major differences. It is in the 5' part of the U3 - LTR region, which had been proposed to be the target for negative regulatory element(s) where the major variability has been found.

Th.C.P.68 PRODUCTIVE HIV-1 INFECTION OF HEPATOCELLULAR CARCINOMA CELL (HCC) LINES IN VITRO.

Cao, Yunzhen*; Friedman-Kien, A.E.*, Huang, Y.X.*; Li, X.L.**; Mirabile, M.*; Zucker-Franklin, D.*; and Ho, D.D.**. *New York University Med. Center, NY, NY.; **Cedars-Sinai Med. Center, Los Angeles, CA. U.S.A.

Objective. To determine the in vitro susceptibility of HCC lines to infection by different strains of HIV-1.
Methods. Five HCC lines, including CZHC-8571, PLC, Hep3B, HePG2 and HUH7 were inoculated with 3 diverse isolates of HIV-1 (HTLV-IIIB, RT, and AL) at multiplicity of infection ranging from 0.002 to 20. HIV-1 expression was monitored by detection of p24 antigen and RT activity in culture supernatants weekly for up to two months, & by immunohistochemical staining, in situ hybridization, & electronmicroscopy (EM) performed on the cells at 6hr, 24h, 3 & 7 days after virus inoculation. The presence or absence of CD4 on HCC lines was shown by immunoflourescence, using anti-CD4 monoclonal antibodies.
Results. Five HCC lines were found to be susceptible to productive infection by three strains of HIV-1 in vitro. Expression of HIV-1 p24 lasted for over 60 days, but its level decreased in proportion to the number of viable cells. P24 was also found in the cells by PAP staining, as were viral RNA by in situ hybridization and HIV-1-like particles by EM. Yet supernatant RT activity was not detected, and rescue of infectious HIV-1 from culture supernatants with H9 cells is negative to date. Despite their susceptibility to infection, all 5 HCC lines were negative for CD4 by immunofluorescence.
Conclusion. CD4-negative HCC lines are productively infectable in vitro by HIV-1 via an unknown pathway. Further, the replication of HIV-1 in HCC lines may be incomplete, and HIV-1-like particles found in the HCC lines may represent defective virions.

Th.C.P.70 HIV1 DNA SEQUENCES DETECTED BY PCR IN SERONEGATIVE, YET ANTI-NEF POSITIVE, INDIVIDUALS.

Françoise Lauré* ****; Courgnaud, V.*; Chamaret, S.***; Raphael, M.*****; Montagnier, L.*** and Bréchot, C. * **.
*INSERM U.75 CHU Necker, Paris, **Hybridotest et ***Unité d'Oncologie Virale, Institut Pasteur, Paris, ****Diagnostics Pasteur, Marnes la Coquette, *****Service d'Hématologie, Pitié Salpétrière, Paris, France.

Objective. To investigate the presence of HIV1 DNA in seronegative individuals at risk of HIV infection.
Patients. 6 subjects : 2 sexual partners of HIV1 positive subjects, 2 haemophiliacs, 2 with lymphomas (non Hodgkin lymphoma : NHL). In addition: 2 anti-nef negative patients (1 with T cell lymphoma and 1 sexual partner of a seronegative anti-nef positive subjects) were tested.
Methods. PCR with 40 cycles and 3 sets of primers (Pol and env genes). Anti-nef were detected through western-blot using a recombinant nef protein (Transgene).
Results. HIV1 DNA sequences were identified in 5 of the 6 anti-nef positive subjects. This included 1/2 haemophiliacs, 2/2 sexual partner of HIV+, 2/2 NHL lymphomas. In addition HIV1 DNA scored + in 2/2 anti-nef negative subjects (with T cell lymphoma and sexual partner).
Conclusions. This study 1) indicates the possibility of HIV infections in apparently seronegative, yet anti-nef positive subjects, 2) will lead to further investigate the potential implications of HIV1 DNA and anti-nef positivity in some subjects with lymphomas.

Th.C.P.72 Susceptibility to HIV-1 Infection of a Human B-lymphoblastoid Cell Line, DG75, Transfected with Subgenomic DNA Fragments of EBV.

Daefler, Simon*; Goldblum, Natan**; Llana, Ted*; Ablashi, Dharam*; Josephs, Steven*; Salahuddin, Zaki*
*Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA **Fogarty International Center, National Institutes of Health, Bethesda, Maryland and Hebrew University-Hadassah School, Jerusalem, Israel

We have previously shown that the presence of the EBV genome and active EBV infection in some Burkitt's Lymphoma cell lines confer the susceptibility to HIV-1 infection in spite of the absence of surface CD4 receptors in these cells. In the present study we used an EBV genome negative Burkitt's Lymphoma B-cell line, DG75, transfected with three different subgenomic fragments of EBV expressing the nuclear antigens (EBNA1 and EBNA2) and the latent membrane protein (LMP), respectively. Immunofluorescence analysis demonstrated CD4 expression in more than 90% of the EBNA1, EBNA2 and LMP transfected cell lines, whereas the antigen could only be detected in less than 4% of the parental DG75 cell line. Unlike the wild type DG75 line the three transfected cell lines were shown to be susceptible to HIV-1 by both IFA and production of virions. Northern blotting of poly(A) selected mRNA of the four cell lines and hybridization to a human CD4 cDNA(pT4B) demonstrated a 3kb band in all three EBNA1, EBNA2 and LMP transfected cells as well as in the wild type DG75 cells. Approximate quantitation indicates equivalent level of T4 mRNA expression in the transfected cell lines as compared to T-cell lines (Hut-78, H9-9).

Th.C.P.73 PROCESSING OF GAG AND POL POLYPEPTIDES AS IN VITRO MODEL FOR PROTEASE INHIBITOR STUDIES IN EUCARYOTIC TARGET CELLS

Wagner, Ralf*; Soutschek, Erwin*; Motz, M.*; Wolf, H.*
*Max von Pettenkofer Institute, Ludwig Maximilian University, München, FRG

Objective. The protease of HIV could be a target for specific inhibition in therapeutic application. Specific proteolytic processing of HIV derived polypeptides has been demonstrated in recombinant E.coli extracts and intact cells. However, it is essential for an inhibitor to demonstrate its uptake into HIV infected cells.
Methods. Recombinant vaccinia viruses were constructed, expressing gag or pol polypeptides respectively in connection with the HIV protease. Processed gag and pol derived proteins were analysed by western blot analysis, with monoclonal and polyclonal sera.
Results. The insertion of the entire gag (p55) encoding sequence resulted in an expression of the gag polypeptide precursor. The addition of the protease sequence in its natural configuration resulted in no detectable processing, due to the missing ability of translational frameshifting in vaccinia virus infected CV-1 cells.
The enforced frameshift due to site directed mutagenesis resulted in a processing of the gag polypeptide precursor. The processed proteins could be easily detected by immunological methods such as western blot analysis with monoclonal antibodies.
Conclusion. With the recombinant vaccinia virus obligatory expressing gag and protease a convenient in vitro system for testing specific inhibitors and their cell permeability was established.

Th.C.P.75 IDENTIFICATION D'EPITOPES SEQUENTIELS DES PROTEINES MAJEURES DE CORE DES VIRUS HIV1 et HIV2.

B. JANVIER[1], P. ARCHINARD[2], B. MANDRAND[2], F. BARIN[1]
1-Lab. Virologie, URA CNRS 1334, TOURS, France, 2-Biomérieux, MARCY L'ETOILE, France.

OBJECTIF : Identification des épitopes séquentiels de la protéine P24 reconnus par des anticorps monoclonaux murins (ACM) et par des IgG purifiées à partir de sérums humains anti-HIV1 ou anti-HIV2, par la méthode "épitope scanning" selon GEYSEN ou PEPSCAN.
METHODES : -Obtention d'ACM après immunisation de souris Balb/c par différents antigènes: virus purifiés inactivés (souches HIV1/HTLV-IIIB ou HIV2/P2B9), protéines P24 purifiées.
-Caractérisation des ACM en ELISA et Western-blot.
-Identification des épitopes reconnus par la méthode de l'épitope scanning après synthèse des 225 hexapeptides couvrant la totalité de la P24/HIV1 (aa 133 à 363 de la P55).
RESULTATS : -10 ACM dirigés contre les protéines P24 ont été obtenus. Testés en Western-blot, ils reconnaissent tous la P24/HIV1 et 5 réagissant également avec la P 24/HIV2.
-Le PEPSCAN réalisé avec les ACM a permis d'identifier 4 épitopes séquentiels :

1 ACM reconnaît la séquence ATPQDLNTML (aa 179 à 188)
3 " " " " " AAEWDRVHP (aa 209 à 217)
5 " " " " " EIYKRWII (aa 260 à 267)
1 " " " " " SILDIR (aa 286 à 291)

CONCLUSION : -Les 5 ACM reconnaissant la séquence EIYKRWII sont ceux qui présentent une réactivité croisée avec HIV2 en Western-blot. La séquence homologue de la P24/HIV2 est DIYRRWIQ.
-Les premiers résultats obtenus avec les IgG humaines mettent en évidence des épitopes reconnus également par nos ACM.
Mots-clés : P24/HIV, épitopes séquentiels, anticorps monoclonaux

Th.C.P.77 MOLECULAR CHARACTERIZATION OF TWO NON-INFECTIOUS HIV-1 ISOLATES.

Roux, Stephan; Boulerice, F.; Lvovich, A.; and Wainberg, M.A. Jewish General Hospital and McGill University, Montreal, Quebec, Canada.

After long-term screening of chronically-infected U-937 cells, we succeeded in isolating two clones of cells which show peculiar cell-virus interactions. In order to better define the properties of these clones, biological and molecular analyses were performed.
The virus-specific proteins of two clones (UHC4 and UHC15) were identified by western blotting using whole virus preparations from the culture supernatants as well as purified membranes from infected cells. No viral proteins nor virus-specific mRNA were detectable in the UHC4 preparations; therefore, we tested this clone for the presence of integrated proviral genome by polymerase chain reaction analysis.
The results show that proviral DNA was present but not expressed. Subsequent binding studies using OKT4A monoclonal antibody were performed and showed that CD4 surface antigen was present at normal levels. Whole virus preparations of cellular clone UHC15 lacked gp120 and gp41 proteins, although normal levels of these proteins were present on the cell membranes. Since surface-labelled cells did not produce virus carrying radioactive gp120 or gp41 (as detected in the infected U-937 control), we suggest that this virus does not bud in close association to its envelope proteins.
Further characterization of these clones should lead to increased understanding of the mechanism of replication and maturation of HIV-1 in cells of monocytic origin.

Th.C.P.74 BIOLOGIC AND MOLECULAR PATTERN OF DIFFERENT HIV ISOLATES FROM ZIDOVUDINE (AZT) TREATED AND UNTREATED AIDS PATIENTS.

García-Sáiz, Alfredo; Bernal, A.; Muñoz, L.; Sanchez-Palomino, S.; Rojas J.M. and Nájera, R.
Instituto de Salud Carlos III, Majadahonda, Madrid, Spain.

Objetive. To compare the replicative ability of different HIV isolates as a marker of replication in probably AZT altered strains.
Methods. Cinetics of replication using different multiplicities of infection (MOI) with human cell lines (H9 and U937) were determined for a set of HIV isolates. The detection of viral replication was established by cytopathic effect, RT activity, p24 antigen and indirect immunofluorescent. Molecular pattern was conducted by restriction enzyme fragment of genomic DNA by Southern blotting.
Results. HIV isolates from AZT treated AIDS patients and untreated could be distinguished by their biologic and molecular pattern. According to their capacity to replicate in vitro some virus differ in the type of cytopatic effect, p24 antigen detection in cell culture supernatant and immunofluorescence antigen in cells. We are currently examining the restriction enzyme pattern.
Conclusion. If the AZT treatment induce probably variant virus with different virulence the biologic characterization could be useful as a prognosis marker of the treatment during the disease progresion.

Th.C.P.76 DIFFERENTIAL SUSCEPTIBILITY TO AZT OF HIV-1 VARIANTS GROWN IN EBV-TRANSFORMED B CELL LINES.

Tremblay, Michel; and Wainberg, M.A.
Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, and Department of Medicine, McGill University, Montreal, Quebec, Canada.

Objective. Three different isolates of HIV-1 were used to determine the potential inhibitory effect of AZT on viral replication in EBV-transformed B cells.
Methods. EBV-transformed B cells were infected with two clinical isolates and the HTLV-III$_B$ strain of HIV-1. These cells were pretreated with various concentrations of AZT (1, 5, and 10 µM) prior to viral inoculation and were thereafter maintained in AZT-containing medium. Presence of HIV-1 infection was determined by antigen capture assay and indirect immunofluorescence.
Results. We have found that three different concentrations of AZT prevented infection of susceptible B cells by one of the clinical isolates (334) of HIV-1. In contrast, no such inhibitory effect was observed with each of a second clinical isolate (336) or with the HTLV-III$_B$ laboratory strain of HIV-1. However, in these latter cases, pretreatment of cells with AZT did cause a drug-dependent retardation in establishment of HIV-1 infection. In addition, no noticeable anti-retroviral effect was observed with EBV-transformed B cell lines that had been pre-infected by HIV-1 prior to AZT treatment.
Conclusion. These results indicate a differential susceptibility to AZT of HIV-1 variants grown in EBV-transformed B cells.

Th.C.P.78 INTERET DE PEPTIDES SYNTHETIQUES DANS L'ETUDE DE VIRUS APPARENTES AU VIH : L'EXEMPLE DES VIRUS SIMIENS

COT Marie Camille(1), BISSONNIER M.(1), JENNINGS M.(2),GEORGE-COURBOT M.C.(3), BOUCHER V.(4), BARRE-SINOUSSI F.(4)
(1) Diagnostics Pasteur, Marnes, France - (2)Université de Californie,Davis, USA
(3) Institut Pasteur,Bangui,République Centrafricaine-(4)Institut Pasteur, Paris, France

Objectif : Etudier divers isolats de virus SIV et leur proximité avec le virus VIH au niveau de l'épitope transmembranaire conservé à l'aide de peptides synthétiques spécifiques (Genetic Systems,USA).
Matériel et Méthodes : Le peptide 39, spécifique du virus VIH1(RILAVERYLKDQQLLGIWGCSGKLIC) et le peptide 41.2.1 spécifique du virus VIH2 (NVTAIEKYLQDQARLNSWGCAFRQVC) miment un épitope immunodominant de la glycoprotéine transmembranaire de chaque virus. Le test PEPTI-LAV 1.2 est un test ELISA (Diagnostics Pasteur) utilisant ces deux peptides fixés sur membrane, qui permet de différencier indirectement la nature des infections sur la base de la réponse sérologique par visualisation d'un spot coloré au niveau du peptide reconnu. 14 sérums de singe ont été testés en PEPTI-LAV 1.2 : 4 singes en captivité inoculés avec diverses souches virales et 10 singes de République Centrafricaine (RCA) naturellement infectés.
Résultats :

Espèce	Nombre	Virus	Origine de l'infection	Peptide 39	Peptide 41.2.1
Rhesus macaque (Centre de primates)	1	SIVmac	Transmise	-	+
	1	SIVsmm		-	+
	1	SIVst		-	+
Patas(capturé en RCA)	1	SIVagm05	"	-	+
Singes verts AGM(RCA)	10	SIVagm	Naturelle	-	+

Tous les sérums de singes infectés naturellement ou inoculés par divers isolats de virus SIV reconnaissent le peptide spécifique du VIH2.
Conclusion:Un test utilisant divers peptides mimant plusieurs épitopes immunodominants de cette famille de lentivirus permet non seulement un complément de diagnostic mais aussi une caractérisation antigénique des virus apparentés au VIH.Dans ce cas de virus simiens leur proximité avec le VIH2 est confirmée.

Th.C.P.79 Dideoxynucleosides Prevent Formation of HIV-1 Provirus During Single Cycle Infection of Macrophages.

James R. Munis, R.S. Kornbluth, and D.D. Richman.
Departments of Medicine and Pathology, University of California, San Diego, and Veterans Administration Medical Center, San Diego, CA, USA 92161.

Dideoxynucleosides previously had been shown not to inhibit low level replication of the lymphotropic LAV-1 strain of HIV-1 in primary human macrophages. In contrast, AZT markedly inhibits the replication of a macrophage-tropic strain of HIV-1 (HTLV-III $_{BaL/85}$) which replicates to high titers ($\geq 10^{6.0}$ $TCID_{50}$/ml) in primary macrophage culture. The effects of 1 uM AZT on the replication of this BaL/85 strain in macrophages were examined using a high multiplicity (m.o.i.= 3) single cycle infection. At several time points after infection, cells were harvested and viral nucleic acids were assessed by PCR amplification of a conserved HIV-1 envelope sequence. In the absence of AZT, envelope DNA (provirus) could be detected by 12 hours after infection, approximately concurrent with the release of viral p24 antigen into the supernatant. In the presence of AZT, no viral DNA or new p24 antigen was detectable during the five day incubation. Viral RNA was measured using one round of reverse transcription prior to DNA amplification. In the AZT treated cells, viral RNA was continuously present up to 48 hours, when it began to decrease steadily during the remainder of the incubation. We conclude that (1) the replicative cycle of this HIV-1 strain in macrophages is approximately 12-24 hours, (2) AZT prevents the formation of HIV-1 provirus in this system, and (3) virion input RNA, in the absence of viral replication, persists in macrophages for more than 48 hours.

Th.C.P.80 QUANTIFICATION OF GP160 FROM HIV BY A "CAPTURE" ELISA.

Åkerblom,L., Fridberger,T., and Villacres,M.
Biomedical Center, BOX 585, S-75123 Uppsala, Sweden.

Objective. To develope a sensitive and quantitative test for gp120/gp160 from HIV-1.
Methods. Polyclonal anti gp160 sera were produced by immunizing rabbits with gp160 (vaccinia) iscoms. The serum IgG was used as "capture" antibody. Detection of gp120/gp160 was done by an indirect method using a panel of monoclonal antibodies reacting with gp120 and gp41. The monoclonal antibodies were detected with horse raddish peroxidase conjugated rabbit anti mouse antibodies. The monoclonal antibodies were produced and selected in our laboratory from spleen cells from mice either immunised with native gp120 or gp160 from Vero cells infected with a vaccinia virus vector.
Results. We were able to detect gp120/gp160 from from different sources sutch as purified virus, culture fluid and HIV infected cells. The detection limit is around 0.5ng. The gp120/gp160 "capture" ELISA is used routinely to measure the production of gp120/gp160 in Vero cells infected with a vaccinia virus vector. The ELISA is also used to determine the yield of gp160 incorporated into gp160 experimentaliscom vaccine. One of the monoclonal antibodies used for the detection of gp120/gp160 recognize a loop region (aa 302 to 338) and neutralizes the HIV IIIB isolate in vitro.
Conclution. The gp120/gp160 "capture" ELISA we have developed is sensitive with a detection limit of 0.5ng. The ELISA is routinely used for screening of HIV envelope gp120/gp160 content in cell cultures.

Th.C.P.81 SEQUENCING OF PCR-AMPLIFIED HIV-1 RELATED SEQUENCES FOUND IN THE DNA OF INSECTS FROM CENTRAL AFRICA.

Moncany, Maurice, L.J.* ; Becker, J.L.** and Montagnier, L.*
* Unité d'Oncologie Virale, Institut Pasteur, Paris, France ; ** Laboratoire de Virologie Moléculaire, Université Paris VII, Paris, France.

Objective. To detect HIV-1 related sequences integrated into the DNA of African insects and to investigate their nature and origin.
Methods. Classical molecular hybridization techniques were first used for the detection of the considered sequences : squash-blot, dot-blot, Southern transfert. For the PCR amplification, we designed primer-oligonucleotides in the gag, env and nef genes. The amplified materials were sequenced with the Taq-polymerase and non-kinased primers, following the technique of Sanger.
Results and conclusion. Screening of more than 5000 insects captured in Central Africa has revealed, using molecular hybridization techniques, the presence of HIV-1 related sequences in the DNA of insects belonging to numerous species. However, HIV-1 probe generally hybridizes mainly two EcoRI fragments of 4.5 Kb and of 3.5 Kb in the insect DNA. This pattern is not in agreement with the restriction map of the described members of the HIV family. We used PCR to amplify these sequences in the gag, env and nef genes. The PCR-amplified DNA was directly sequenced by a new technique using non-kinased primers and the Taq-polymerase allowing a higher temperature of reaction, which overcomes the blocks induced by secondary structures of the DNA. Sequence results, with evidence of important rearrangements in the env gene, will be presented.

Th.C.P.82 IMPROVED ASSAYS FOR DNA-POLYMERIZING ENZYMES, BY THE USE OF 5-^{125}I-IODODEOXYURIDINE TRIPHOSPHATE, ILLUSTRATED BY DIRECT QUANTIFICATION OF HIV-RT ANTIBODY (AB).

Neumüller M., Karlström A.R., Kallander C. F.R.& Gronowitz J. Simon
Dept of Medical Virology, Uppsala University, Box 584, BMC, 751 23 Uppsala, Sweden.

The design of a procedure to synthesize ^{125}I-IUdRTP in one step from ^{125}I-IUdR, followed by a onestep shielded purification giving an allover recovery between 50-75% and a >90% pure product within 8 hours is described. The sensitivity and specificity for the ^{125}I-IUdRTP compared to ^{3}H-TTP as a substrate in DNA-polymerase (DNAp) and reverse transcriptase (RT) assays was evaluated with different specimen, including purified recombinant HIV-RT. The ^{125}I-IUdRTP was accepted equally as well as ^{3}H-TTP and depending on enzyme specimen a 10-25 fold increase in assay sensitivity was found when using ^{125}I-IUdRTP at low substrate concentration. Thus the new assay could detect DNAp activity from <5 HSV2-infected cells, while $<0,3\times10^{-12}$ g sufficed for detection of purified recombinant HIV-RT. Due to the small HIV-RT amounts necessary for detection, it was possible to quantitate HIV-RT ab, without previous purification of immunoglobuline. Analyses of 31 HIV-infected individuals showed that all had HIV-RT ab and the serum needed for 50% inhibition of the HIV-RT activity corresponded to a 100-fold less immunoglobuline (i.e. 0.02-31.4µg) than earlier reported.... It is concluded that ^{125}I-IUdRTP both simplifies the assay, by excluding the need of TCA-precipitation and of scintillation coctail, and that it is an excellent substrate for improved detection and quantitation of diffe-rent DNA-synthetizing enzymes, and thus also for their blocking abs.

Th.C.P.83 Multiple Sclerosis and Retrovirus: Screening with retroviral probes of cDNA library constructed with poly A+ RNA from active lesions

S Lefebvre, J F Bureau, S Chirinian, M Brahic
Laboratoire des Virus Lents, Département de Virologie, Institut Pasteur Paris, France

Multiple sclerosis (MS) is a chronic neurologic disease of unknown etiology. The inflammatory demyelinated lesions (plaques) are found in the central nervous system (CNS). Briefly, in MS plaques the oligodendrocytes that are producing the myelin sheets are destroyed leaving intact axon more spaced.

One of the best animal model for MS is a demyelinating disease in sheep caused by visna virus. Visna virus belongs to the lentivirus subfamily of retrovirus and is related to HIVs. Recently, another retrovirus was shown to be associated with chronic neurologic disorders. Studies indicated that the oncovirus HTLV-I has a causal role in tropical spastic paraparesis (TSP) as well as in chronic progressive myelopathy. Attempts were also made to associate HTLV-I with MS. The results were limited and inconclusive. Since three of the four known human retroviruses can cause neurologic disease, we try to identify retroviral nucleic acid from MS plaques.

RNA was isolated from active MS plaques. Purified poly A+ RNA was used to construct a cDNA library in lambda gt 10. A low-stringency hybridization with specific retroviral probes was used to screen the library. Screening of the first 10^5 clones was negative. However, these preliminary results will be discussed in regard that they do not exclude the possibility of a new retrovirus.

Th.C.P.84 A SINGLE TUBE, ONE-STEP PURIFICATION AND ASSAY FOR THE ANALYSES OF REVERSE TRANSCRIPTASE ACTIVITY (RT) IN CRUDE SPECIMENS AND SOME APPLICATIONS WITH REFERENCE TO HIV.

Gronowitz J. Simon, Neumuller Magnus, *Bhikhabhai Rama, *Unge Torsten, and Kallander Clas F.R. Dept of Medical Virology, and *Dept of Molecular Biology, Uppsala University, Box 584, BMC, 751 23 Uppsala, Sweden.

Based on ^{125}I-IUdRTP as a substrate (see abstract), a further simpli-fied and improved procedure for quantitation of HIV-RT, using solid-coupled template, has been designed. In principal, the enzyme sample is mixed with a reaction solution containing the radiolabeled substrate and other necessary components, wherafter the solid-coupled odT primed prA is added. Next the reaction proceeds for desired time, wherafter the product is separated from substrate by washing the solid phase with a salt solution. Then the incorporated radioactivity is directly measured in a γ-counter. For the analyses of RT activity in crude specimens, containing disturbing substances or enzymes like RNAse, TTPase etc, the assay is improved by adding a primary step as follows; the specimen is first added to the solid-coupled primed template and kept for 10-20 min at 4° C, in order to let the RT bind to the template, next the disturbing factors are washed away, wherafter the amount of RT on the solid phase is determined by adding radiolabeled substrate and further proceeding as indicated above. Further, data showing that the assay can be improved by addition of ribonucleotide, ie CTP and by addition of pG will be given. Analyses using Sepharose or plastic balls as solid phase have been done, and a high recovery of activity from mixtures of recombinant HIV-RT with lymphocyte- or crude bloodcell-extracts was obtained. Further analysis of clinical specimen are given in abstr. ( )

Th.C.P.85 CHARACTERIZATION OF AN HIV-2 RELATED VIRUS WITH A SMALLER SIZED ENVELOPE PRECURSOR

Krust, Bernard ; Rey, M.A. ; Laurent, A.G. ; Oustard, D. ; Montagnier, L. and Hovanessian, A.G.
Unité d'Oncologie Virale, Institut Pasteur, Paris 15, France.

Objective : A new cytopathic isolate of the human immunodeficiency virus (HIV) related to the HIV-2 strain was isolated (HIV-2 MAN) from peripheral blood lymphocytes of an Ivory Coast patient with AIDS.
Results : HIV-2 MAN could be differentiated by its envelope precursor and external glycoprotein which are 20kd molecular weight smaller than those of HIV-2 ROD isolate. Furthermore, the apparent molecular weight of the major core protein of HIV-2 MAN is 27kd instead of 26kd as in HIV-2 ROD isolate. In addition, the product of the vpx gene which is a characteristic feature of the HIV-2 strain, is 14kd in HIV-2 MAN compared with 16kd in HIV-2 ROD. In contrast to these, the envelope precursor of HIV-2 MAN forms a transient dimer during its maturation as it is the case for HIV-2 ROD. In both cases the transmembrane proteins are 36kd and exist as homodimers of 80kd. Endo H digestion experiments indicated that the 20kd difference between the two HIV-2 isolates is due to their polypeptide moiety. Furthermore partial proteolysis with the V8 protease gave two distinct polypeptide patterns, thus suggesting that the differences between the external envelope proteins of the two HIV-2 isolates are due to their amino-acid composition. Accordingly, polyclonal antibodies raised against HIV-2 ROD envelope do not recognize the corresponding envelope proteins of HIV-2 MAN by immunoblotting and immunoprecipitation assays.
Conclusion : These data illustrate that analysis of viral proteins could be useful for a rapid and an efficient method to characterize new HIV isolates.

Th.C.P.87 INFECTION AND REPLICATION OF HIV-1 IN HUMAN BRONCHO-ALVEOLAR AND PERIPHERAL BLOOD MONOCYTES-MACROPHAGES

[illegible], SALAUN D., PALMARI G., CHERMANN J.C.

Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cédex 9 - FRANCE.

Objective : To characterize the mode of penetration replication and transmission of HIV in monocytes - macrophages (MO.MΦ).
Methods : MO.MΦ were isolated by plastic adherence, from broncho alveolar lavages (BAL) from AIDS patients or from peripheral blood (PB) from healthy donors and then infected in vitro. Cells were monitored for HIV by reverse transcriptase (RT), electron microscopy (EM) and genomic DNA analysis (Southern).
Results : Virus expression measured by RT, was never detected in direct cultures of MO.MΦ infected in vivo or in vitro. Cocultures with a sensitive cell line (CEM) or normal PBL-PHA blasts, after freezing - thawing the adherent cells, allowed virus production. Efficient blockage of virus infection on PB MO.MΦ was obtained using low dilutions of human HIV seropositive sera and using monoclonal antibody (MAb) against CD4 (13B8.2). Other MAbs directed against different CD4 epitopes are currently investigated. EM showed the presence of a high amount of viral particles enclosed into cytoplasmic vacuoles of MO.MΦ while no RT was measurable. Futhermore, no external budding has been seen on the same cells. Preliminary results using Southern analysis indicated that viral DNA was not integrated in infected MO.MΦ.

Th.C.P.89 EXPRESSION OF VIRAL AND CELLULAR GENES IN CELLS INFECTED BY THE HUMAN IMMUNODEFICIENCY VIRUS, HIV-1, AND THE SIMIAN IMMUNODEFICIENCY VIRUS, SIV/Mne.

Katze, M.G.[1,2]; Morton, W.R.[1]; Benveniste, R.E.[3]; Foy, K.[2]; Corey, L.[1]; Agy, M.B.[1,2]. [1]Department of Microbiology, University of Washington, Seattle, Washington; [2]Regional Primate Research Center, University of Washington, [3]Lab of Viral Carcinogenesis, NCI, Frederick Cancer Research Center, Frederick, Maryland, U.S.A.

The current study was undertaken to define the complex regulatory events occurring *in vivo* in CD4-positive lymphoid cell lines infected by HIV-1 and SIV/Mne. Initial efforts were directed at measuring viral and cellular mRNA and protein levels in HIV-infected CEM cells. Northern blot analysis revealed that viral-specific mRNAs could be detected as early as 2 days after infection of CEM cells by HIV-1. Maximal accumulation of the major species of viral mRNAs occurred by 5 days post-infection (PI). In accordance with these results, the synthesis of viral-specific proteins was readily detectable at 2 days PI and peaked dramatically at 4 and 5 days PI. Immunofluorescence studies showed that >90% of CEM cells were infected by 4 days PI. Cell viability studies, using trypan blue exclusion, demonstrated that >75% of infected cells were still viable at 4 and 5 days PI. We next examined the effects of HIV-1 infection on cellular mRNA and protein synthesis. The steady state levels of actin and GADPH mRNAs steadily declined during virus infection with actin mRNA levels down ten-fold by 5 days PI in HIV-1 infected CEM cells. There was a corresponding progressive decrease in cellular protein synthesis during infection at the time when viral protein synthesis was found to peak. In parallel studies, we examined the kinetics of viral protein synthesis in cells infected by SIV/Mne. In contrast to the results obtained with HIV-1, little or no viral protein synthesis was detectable in SIV-infected CEM cells. However, in SIV-infected C8166 cells, high levels of the SIV-specific proteins were detectable by 2 days PI. As was the case in the HIV-CEM system, overall levels of cellular protein synthesis declined during SIV infection of C8166 cells. Efforts are in progress to delineate the mechanisms responsible for the decreases in cellular mRNA and protein levels in HIV- and SIV-infected cells.

Th.C.P.86 NEW TESTS USING SYNTHETIC PEPTIDES IN THE DIAGNOSIS AND TYPING OF HIV INFECTIONS IN HUMAN.

MARTIN Jacques*, BETTINGER S. *, ADDA D.*, TSAI P.K.**, RICHARDSON C.**, SOMME G.*
* CLONATEC 60 Rue de Wattignies 75580 PARIS Cedex FRANCE
** SYNTRO , SAN DIEGO , CA, USA

Objective : Microtiter ELISA using two synthetic peptides derived from transmembrane glycoprotein of HIV1 and HIV-2 were optimized. One allows to detect anti-HIV antibodies (TOTAL HIV Ab (1+2)) and the other one allows to type specifically anti HIV-1 and anti-HIV-2 antibodies (TYPING HIV Ab (1 or 2)) .
Methods : The TOTAL HIV Ab assay involves microwells coated with a blend of the two HIV-1 and HIV-2 peptides and the TYPING HIV Ab involves strips coated with HIV-1 peptide only and strips coated with HIV-2 peptide only on the same plate. The duration of the test is 35 minutes long (15 min. serum incubation, 15 min. conjugate incubation and 5 min. color devlopment).
Results : In a preliminary study, 302 sera were tested ; 191 anti HIV sera and 111 negative sera. Among the 191 positive sera : 132 samples are from Europ origin, 41 samples from Africa origin, 11 samples are seroconversion HIV- 1 and 7 samples are anti-HIV-2 sera (Africa origin). Among the 111 negative sera; 66 samples from Europ origin, 41 samples Africa origin and 4 samples are false-positive with core reactivity. The performances of TOTAL HIV Ab and TYPING HIV Ab are respectively of 99.1% and 99.3% for sensitivity and 100%, 100% for specificity. The cross-reactivity of sera in TYPING HIV Ab is 2.1% for anti-HIV-1 sera in HIV-2 strip.
Conclusion : These first results show the advantages of ELISA kits using synthetic peptides for detection of HIV infections and also to type the infectious virus, that is a very important information for epidemiologic studies. We thank Dr. Ph. Pouletty.

Th.C.P.88 ZIDOVUDINE SERUM LEVELS AND HALF-LIFE IN PATIENTS ON CHRONIC MAINTENANCE HEMODIALYSIS

Stellbrink,H.J.*; Averdunk,R.**
*Universitätskrankenhaus Eppendorf,Hamburg; **Auguste-Viktoria-Krankenhaus,Berlin,FEDERAL REPUBLIQUE OF GERMANY

Objective: To determine zidovudine serum levels and half-life in HIV+ patients on chronic maintenance hemodialysis due to renal failure.
Methods: Zidovudine serum levels were determined with an HPLC assay at 0, 60,120 and 180 min. after single dose oral administration and during hemodialysis sessions. 2 patients with HIV-1 infection have entered the study so far. 1 pat. is ready for evaluation, 1 is still under study.
Patient characteristics:

age (yrs)	sex	HIV risk factors	cause of renal failure	CD4+ (c/nl)	p24 antigen	other	
42	male	homosex.	acute GN	0.31	-	OHL	evaluable
50	male	transfus.	IgA nephritis	0.15	≥1000 E/ml	OHL	under study

None of the patients had impaired hepatic function.
Results: Zidovudine peak levels were reached after 2 h following oral administration of 100-200 mg of AZT. They were within the therapeutic range (1.67 umol/l). Half life was not prolonged and was not significantly altered by hemodialysis in the first pat. studied so far. The results of both will be ready for presentation in detail.
Conclusion: Serum half-life of zidovudine may be normal in renal failure and patients on chronic hemodialysis. Delayed and low peak levels may be due to impaired absorption. Because of these results different from the observations of others (Deray et al. 1988) a pretherapeutic assessment of the basic pharmacokinetic parameters seems justified in this setting.

Th.C.P.90 IDENTIFICATION OF HIV-1 PACKAGING SIGNALS

Lever, Andrew; Gottlinger, H.; Haseltine, W.; Sodroski, J.
Dana-Farber Cancer Institute, Harvard Medical School,
Boston, MA U.S.A.

Objective: To define regions of the HIV-1 genome required for packaging HIV-1 RNA into virions.

Methods: Deletions in the area 3' to the splice donor and 5' to the gag ATG were made using site directed mutagenesis. Virion RNA content was determined by RNA dot-blot analysis.

Results: Deletions of as little as 19 base pairs in this region produced viruses which produced abundant viral protein and morphologically normal virions as seen by E.M. These virions displayed a *cis*-acting replication defect and packaged virion RNA at an efficiency of 2% of wild-type virus.

Conclusions: A region important for packaging HIV-1 RNA into virions has been defined. Mutation of this region inhibits both cell free and cell to cell viral transmission.

Th.C.P.91 DIFFERENTIAL INHIBITION OF HIV VARIANT INDUCED SYNCYTIUM FORMATION BY SEROPOSITIVE PEDIATRIC SERA

Steinhauer, E.; Sangeakphisarn, R.; Cahill, O. and Rubinstein, Arye
Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.

Objective. To assess the ability of sera from HIV seropositive children to inhibit in vitro syncytium formation induced by different HIV-1 variants.
Methods. Sera were incubated with supernatant from H-9 cells productively infected either with HIV-1-IIIB or -RF2. The virus-serum mixtures were incubated with CEM-SS cells plated on poly-L-lysine coated 96-well plates. Syncytia were counted after 5 days incubation at 37°C.
Results. Each serum was initially tested for its ability to inhibit in vitro syncytium formation induced by HIV-IIIB. Four of the sera showed low level inhibition (20-40%). Three other samples exhibited intermediate inhibition (40-60%) and the remaining 3 sera showed high neutralizing activity (95-100%). The same sera were subsequently tested for their ability to inhibit HIV-RF2 induced syncytium formation. Six sera showed equivalent neutralization of both variants. Of the remaining 4 samples, 3 exhibited 2-fold increase in inhibition of RF2 whereas the remaining 1 sample did not neutralize RF2.
Conclusions. Serum from HIV seropositive children showed inhibition of HIV induced syncytium formation in vitro. Sixty percent of the samples showed equivalent neutralization of 2 different HIV-1 variants, whereas significant differences were observed in 40% of the samples. The development of HIV disease has been shown to correlate with the emergence of HIV-1 variants which in vitro, are progressively more cytopathic. Neutralization of a range of HIV strains may be prognostic of improved clinical outcome.

Th.C.P.92 HIV-1 INFECTION OF HUMAN MONOCYTE CULTURES; IMPLICATION FOR SILENT INFECTION

Valentin A(1), Albert J(1,2), Fenyö EM(1), Asjö B(1).
1. Department of Virology, Karolinska Institute and 2. Department of Virology, National Bacteriological Laboratory, Stockholm, Sweden.

OBJECTIVE To study HIV-1 infection of normal peripheral blood monocytes/macrophages.
METHODS Monocyte cultures were prepared from peripheral blood mononuclear cells (PBMC) recover by Ficoll-Hypaque gradient centrifugation. PBMCs were cultured in RPMI medium containing 10% HIV negative human serum and 20% FCS. After five days non-adherent cells were discarded. The monocyte cultures were infected with viruses isolated from primary PBMC of HIV-1 seropositive individuals. Two months after infection PHA-stimulated normal PBMC were added to the monocyte flasks in RPMI medium with 10% TCGF. Virus infection was monitored by reverse transcriptase (RT) activity and presence of viral antigen (p24) in culture medium, as well as by immunofluorescence (IF) of infected cells.
RESULTS Viral replication in monocytes was transient and could be detected by antigen assay in 11 cultures and by RT assay only in 2 cultures (of 14). Even if virus replication appeared to be absent for up to two months after infection, the presence of virus could be demonstrated in 12 of 14 monocyte cultures by cocultivation with PHA-stimulated PBMC.
CONCLUSION Our results show that HIV-1 infection of normal monocytes/macrophages can lead to a silent or latent infection. Such persistently infected, non producing cells, may conceivably serve as infectious reservoir in the infected individual and spread infection to other susceptible cells for a long time.

Th.C.P.93 EFFECT OF CALCIUM CHANNEL BLOCKERS ON HIV-1 EXPRESSION IN LYMPHOID CELLS.

Harbison, Mary*; Kim, S**; Baltimore, D**; and Hammer, S*.
*New England Deaconess Hospital, Harvard Medical School, Boston, MA;
**Whitehead Institute, Cambridge, MA, U.S.A.

Objective: To determine the effect of the calcium channel blockers (CCB's) verapamil (V), diltiazem (D), and nifedipine (N) on the replication of HIV-1 and the expression of the HIV LTR in lymphoid cells.
Methods: CEM cells were exposed to CCB's at 0, 25, 50, and 75 uM for 1 hour before inoculation with HIV-IIIB or medium control. Drug concentrations were maintained in the cultures, which were monitored for RT activity, fixed cell immunofluorescence (IFA) for p24 antigen, and cell viability. The effect of CCB's on HIV LTR expression was determined by transfection of CEM cells with LTR-chloramphenicol acetyltransferase (CAT) plasmid constructs, exposure to 50 uM V or D for 48 hours, and assay of CAT activity.
Results: Peak RT and % p24 IFA+ cells were seen 3-4 days earlier in V and D treated cultures vs controls. N had no effect. Results, day 6 post infection:

	RT ($\log_{10}$ cpm/ml)	p24+ Cells (%)	Viability (%)
V 75 uM	5.70	63	63
D 75 uM	5.70	65	80
Control	4.22	5	99

In HIV LTR-CAT studies, V and D at 50 uM induced consistent 5-10-fold increases in CAT activity.
Conclusions: (1) CCB's can markedly enhance HIV-1 replication in lymphoid cells; (2) This effect may be related to activation of the HIV LTR; (3) Agents which affect signal transduction can be used to further our understanding of the control of HIV replication.

Th.C.P.94 A RAPID AND SENSITIVE PLAQUE ASSAY OF HIV-1 ON C8166 CELLS

Zhu,Z.*; Chen,S.*; Weiss,R.A.** and McIntosh, Kenneth*
*Children's Hospital, Harvard Medical School, Boston, MA,USA
**Chester Beatty Institute, London, England.

Objective. To develop a sensitive and simple assay to measure the infectivity of human immunodeficiency virus (HIV-1).
Methods. A syncytial plaque assay was developed using C8166 cells (kindly supplied by R. Gallo), a CD4+ lymphocytic line derived from cord blood and superinfected with HTLV-1. The cells were adhered to plastic with poly-L-lysine, infected, and overlaid with agarose. After 2-3 days' incubation neutral red was added in a 2nd overlay, and syncytial plaques were counted 18 hours later using low-power or dissecting microscopy.
Results. Two strains of HIV-1, IIIB and RF, were tested, and both produced giant cells large enough to be easily recognized as plaques after staining. There was a linear correlation between number of plaques and virus dilution. The sensitivity of the assay was almost identical to that of $TCID_{50}$ tests. Plaques were specifically inhibited by neutralizing antibody. Two of 4 new isolates of HIV obtained from pediatric AIDS cases similarly formed plaques. The assay has been used to determine the neutralizing antibody titers in multiple serum specimens from children with HIV infection.
Conclusion. A plaque assay of HIV-1 on C8166 cells has been developed which readily permits the determination of infectivity in standard and new clinical isolates and quantitation of neutralizing antibodies in human sera. The assay is rapid, sensitive, reproducible, and easy to perform.

Th.C.P.95 PROCESSING AND ASSEMBLY OF HIV-1 CORE ANTIGENS EXPRESSED BY RECOMBINANT VACCINIA VIRUS

Hu, Shiu-Lok*; Travis, B.M.*; Sridhar, P.*; Dykers, T.*; Garriques, J.*. *Oncogen, Seattle, WA, USA.

Objective: To demonstrate processing and assembly of HIV-1 core antigens expressed by recombinant vaccinia virus and to study the effect of viral protease on these processes.
Methods: Recombinant vaccinia viruses have been constructed that contain the gag ORF and varying extents of the pol ORF of HIV-1. Biosynthesis of HIV-1 core antigens was studied by serlogical assays and the assembly of core structures detected by electron microscopy.
Results: HIV gag antigens are efficiently expressed by all recombinants tested. Recombinants lacking the protease-encoding region direct the synthesis of gag antigen precursor p55 and processing intermediate p40 only. Those containing the protease region direct synthesis of the processed products p24 and p17 as well. Surface flourescence is detected by anti-p24 MAb in 10-15% of the infected cells and up to 15% of the core antigens synthesized is released into the medium. Particles of 100nm diameter are present in recombinant-infected cells, even in the absence of viral protease functions.
Conclusions: HIV-1 core antigens are efficiently expressed and processed by recombinant vaccinia virus infected cells, indicating the presence of viral protease function and successful read-through of the gag and pol ORF's. Recombinant-made gag antigens are assembled into viral core-like structures. This process is independent of any other HIV-specific functions, including that of the viral protease.

Th.C.P.96 CHARACTERIZATION OF HIV-1 PROTEINS EXPRESSED BY VACCINIA VIRUS AND E. COLI.

Atsushi,Yasuda*; Kojima,A.**;Okamoto,T.***;Chiba,J.**; Sata,T.** and Kurata,T.**.
* Nippon Zeon Co.,LTD.,Kawasaki,Japan. ** NIH Japan,Tokyo,Japan. *** Natl. Cancer Center Inst.,Tokyo,Japan.

Objective. To examine immunogenicity of HIV-1 gag proteins, P17 and P24, reverse trancriptase (RT) and vif product. Methods. The DNA fragments representing P17 or P24 of gag protein, RT or vif protein as well as the sequences spanning from gag to vif were expressed both in recombinant E. coli and in recombinant vaccinia virus (RVV). These sequences were prepared from a HIV-1 clone pBH10 by restriction endonuclease digestion and/or site-directed mutagenisis, and inserted into a bacterial expression plasmid pOR540 and vaccinia virus genome. HIV-specific proteins expressed from the recombinants were detected and identified by indirect fluorescence antibody (IFA) and western blot analyses, using polyclonal and monoclonal antibodies against HIV-1 proteins. Results and conclusion. Expression of the proteins reacted with patients' sera and monoclonal antibodies was observed except vif-constructs in both RVV-infected cells and E. coli transformed with recombinant plasmids. The production of HIV antigens in vivo was also demonstrated at the dermal sites inoculated with RVV by IFA. For preliminary immunological analysis, rabbits were inoculated with RVV expressing P17 and serum samples were tested for specific responses to P17 protein. Considerable levels of anti-P17 antibodies are not detected so far. Immunogenicity of other RVV and E. coli-derived HIV proteins is presently under research.

Th.C.P.97 HIV TYPE 1 SPECIFIC ANTIBODIES IN CEREBROSPINAL FLUID MEDIATE CELLULAR CYTOTOXICITY AND NEUTRALIZATION.

Chiodi F(1), Ljunggren C(1,2), Broliden PA(1,2), Norkrans G(3), Jondal M(2), Fenyö EM(1).

1.Department of Virology and 2. Department of Immunology, Karolinska Institute, Stockholm, Sweden. 3. Department of Infectious Diseases, Östra Hospital, Gothenburg, Sweden

OBJECTIVE To investigate the presence of antibodies mediating HIV-1 specific cellular cytotoxicity (ADCC) and neutralizing activity in cerebrospinal fluid (CSF) and serum of HIV-1 infected subjects.

METHODS In ADCC assay monocytoid cell line U937 clone 2 was used as target cells; PBMC, obtained from HIV seronegative blood donors were used as effector cells. In neutralization test, virus was incubated fo 60 min (37 C) with heat-inactivated serum or CSF. The serum-virus mixture was added to PBMC (60 min, 37 C) and virus replication assayed by HIV antigen capture ELISA. Virus isolates from blood and CSF were used in the different assays.

RESULTS ADCC-mediating antibodies against target cell infected with the IIIB strain of HIV-1 were present in both CSF and sera from HIV-1 infected subjects, 32% and 60%, respectively. The frequency of ADCC positice CSFs was comparable for the different clinical stages of the disease.

Serum antibodies neutralized blood isolates more frequently than CSF isolates, 53% and 35%, respectively.Only 3 (7%) of the CSF specimens contained neutralizing activity to the CSF derived isolate and none to HTLV-IIIB.

CONCLUSION Our results indicate that both ADCC-mediating and virus neutralizing antibodies may be intrathecally synthesized.

Th.C.P.98 IN VITRO, UNE HEURE D'EXPOSITION A UNE MICROMOLE D'AZT PROTEGE DES LYMPHOCYTES DE L'INFECTION HIV PENDANT PLUS DE QUARANTE HUIT HEURES.

Mathez, Dominique*; Paul, D.** et Leibowitch, J.*
*Hopital Raymond-Poincaré/Université René-Descartes, Garches/Paris-ouest, France; **Abbott Laboratories, North Chicago, Etats-Unis.

Objectifs: rémanence de l'AZT (effet anti-rétroviral) dans des lymphocytes après exposition des cellules pendant une heure à des concentrations extra-cellulaires d'AZT équivalentes à celles obtenues en clinique avec une prise orale unique de 200 mg.

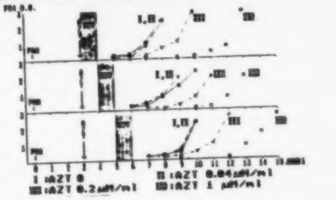
Méthodes: 500 000 lymphocytes stimulés à la PHA (1/10000) 3 jours plus tot sont incubés une heure avec l'AZT (0.02 à 1.0 micromoles), lavés, remis en culture (IL-2 R-Uclaf/SVF/RPMI), et exposés à HIV milliporé (=500-900 picogrammes p24), immédiatement, 24 ou 48 heures après élimination de l'AZT du milieu. Chaque jour, la moitié du milieu est renouvelé par du milieu frais. Le dosage de p24 surnageant (immuno-capture) et l'immunofluorescence p24 intra cellulaire (monoclonal) assurent le monitoring des cultures (répliques de 2).

Résultats:

1) avec des PHA-blastes

2) avec des lymphocytes d'abord quiescents, puis stimulés à la PHA, et alors exposés chaque 24 ou 48 heures pendant une heure à l'AZT, les résultats sont identiques.

Conclusions, en prenant en considération le temps de latence de 3 jours irréductible entre inoculation et expression HIV mesurable, la durée de vie anti-rétrovirale de l'AZT intralymphocytaire serait d'environ 4 jours.



Th.C.P.99 DETECTION OF THE NEF CELLULAR PROTEIN BY SYNTETIC MONOCLONAL ANTIBODY FROM HIV INFECTED SUBJECTS

Pezzella Mario+; Anastasi,A.M.++, Vonesch,N.+; Marcolini,S.++ Sturchio,E.+ and De Santis,R.++
+ Institute Infectious Diseases, Policlinico Umberto I, University of Rome;
++ Biotechnology Department, Menarini Ricerche Sud, Pomezia, Italy

Objective. To investigate the presence of NEF gene product of HIV in peripheral blood mononuclear cells (PBMCs) from anti-HIV seropositive and seronegative individuals at risk for AIDS (ELISA and Western Blot tests).

Methods. We have selected and synthesized by Marrifield solid-phase methodology a six aminoacid sequence in a region of the NEF protein, previously found to be immunogenic. After carrier conjugation, the peptide was used to immunize Balb/c mice in order to obtain NEF-specific monoclonal antibody. Cytocentrifuged PBMCs from 6 anti-HIV seropositive subjects and their seronegative regular heterosexual partners, previously found to be HIV infected by "in situ" hybridization with DNA probe, has been studied. The immunohistochemical reactivity of the NEF peptide specific antibody was visualized by a second antibody alkaline-phosphatase conjugate anti-mouse IgG. Positive and negative controls were performed by using HIV non infected and infected H 9 cell culture lines and healthy seronegative blood donors.

Results. An intracytoplasmic granular staining has been observed in three seropositive and in two seronegative subjects.

Conclusion. NEF protein is expressed "in vivo" and may play a role in pathogenesis in the natural host.

Th.C.P.100 QUANTIFYING HIV INFECTIVITY

Layne, Scott P.*; Spouge, John L.; Dembo, Micah.
*Los Alamos National Laboratory, University of California, Los Alamos, NM, USA,
**Laboratory of Mathematical Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD USA

Objective. We present a model of the kinetic processes in viral infectivity assays. We show how the model is used for designing and analyzing viral infectivity assays, and discuss how it applies to questions such as – How many infectious virions are in an inoculum? How virulent are the virions in an inoculum? How stable are the virions in an inoculum? How effective are various chemical agents against the virions? How effective are immunoglobulins from infected individuals in neutralizing the virions?

Methods. Our model simulates the three overall steps that have been suggested for HIV's infective process. First, HIV diffuses to a target cell's surface. Second, gp120 on the virus' surface and CD4 on the target cell's surface form a bimolecular complex. Third, interactions involving CD4, gp120 and gp41 promote fusion of HIV envelope with target cell membrane, resulting in entry of the viral core.

Conclusion. We have used the model to calculate the gp120-sCD4 association constant (k_{assoc}) directly from viral infectivity assays. We find $k_{assoc} = 3\times10^{-9}\ M^{-1}$, in agreement with equilibrium dialysis methods. We also report the values for the other parameters defined below.

Results. The model quantifies four rate-constants from viral infectivity assays: k_t = rate constant for successful infective contact (tropism) between virus and a CD4+ target cell, k_s = rate constant for spontaneous disassociation (shedding) of gp120 from gp41, k_n = rate constant for non-specific killing (e.g., by enzymatic degradation, nonoxynol-9, etc.) of virions, and k_{assoc} = association constant for a gp120 blocking agent (e.g., soluble CD4 protein) or anti-gp120 immunoglobulin. These rate-constants are derived by straightforward graphical techniques.

Th.C.P.101 HOST CELL TROPISM OF HIV STRAINS: COMPARISON OF REPLICATION IN PERIPHERAL BLOOD LYMPHOCYTES AND MONOCYTE-DERIVED MACROPHAGES.

Ronald Collman, *H Friedman, S Douglas, R Walker, N Hassan, B Godfrey, J Hastings, N Nathanson*. *University of Pennsylvania Medical Center, Philadelphia, PA* U.S.A.

Objective. To develop a model of macrophage infection with representative strains of human immunodeficiency virus (HIV) of varying host cell tropism.

Methods. We have established a system for the extended culture of monocyte-derived macrophages. Using three prototype strains (3B, DV and SF162) we have established a model for permissive and non-permissive macrophage infection and compared the replication of these strains in primary macrophages and lymphocytes to standard lymphocytoid and monocytoid cell lines.

Results. All three strains replicate to high titer in peripheral blood lymphocytes. In macrophages strain SF162 replicates to intermediate titer with production of viral antigens and release of infectious virus while DV replicates to low levels producing viral protein and minimal free virus, and 3B fails to replicate significantly. In contrast, both the monocytoid line U937 and the T cell line SUP-T1 support replication of 3B and DV but not SF162.

Conclusions. All reference strains examined so far replicate freely in PBL's; monocyte-tropic strains replicate in macrophages but to lower titer than in PBL's. The monocytoid cell line U937 and T cell line SUP-T1 may not represent adequate surrogates for the corresponding primary cell type. This matrix is being used to isolate and characterize fresh clinical isolates from varying sources, study the cellular and viral determinants of HIV host cell tropism, examine the role of CD4 in viral entry and compare the neutralizing and (potentially) enhancing epitopes of macrophage- and lymphocyte-tropic viruses.

Th.C.P.102 SPECIFICITY OF MURINE ANTIBODIES TOWARDS EPITOPES OF HIV-1

Khuzaie, Rula; Bernatowicz, A.; Pingel, S.; Streckert, H.J.
Med. Microbiology and Virology of the Ruhr-University, Bochum, Fed. Republic of Germany

Objective: Reactivity of murine antibodies with synthetic peptides corresponding to epitopes of the viral proteins was studied

Methods: Mice were immunized with purified HIV-1. Hybridomas were produced and selected by ELISA with plate fixed HIV-1 proteins and immunofluorescence. Antigen specificity of the elicited antibodies was determined. Reactivity with synthetic peptides corresponding to HIV-1-gag aa 105-115, aa 129-135, and HIV-1-env aa 507-518, aa 512-518, aa 597-611 was observed in ELISA.

Results: Murine antibodies recognized the synthetic peptides in different degrees. Peptide HIV-1-env aa 507-518 was best recognized, all antibodies reacting with aa 512-518 were included. Peptide HIV-1-gag aa 129-135 was only recognized by a single antibody.

Conclusion: Murine antibodies recognize epitopes in synthetic peptides that were previously found to be immunogenic in human.

Th.C.P.103 SINGLE AMINO ACID SUBSTITUTIONS IDENTIFY AMINO ACIDS CRITICAL FOR RNASE H ACTIVITY AND REPLICATION OF HIV.

Repaske, Roy; Clavel, F. and Maudru, T. D.
LMM, NIAID, National Institutes of Health, Bethesda, MD, U.S.A.

Objective. To identify amino acids in the HIV pol gene critical to the function of RNase H.
Methods. Site-directed mutagenesis was used to substitute either of two conserved retroviral pol amino acids (aspartic acids) in the putative RNase H domain in a molecularly cloned infectious HIV (pNL4-3). HIV particles produced by SW480 cells following transfection of the mutant DNAs were harvested, evaluated for RT activity and for infectivity on A3.01 cells. RT and RNase H activities of the partially purified mutant RTs expressed in E. coli were determined.
Results. SW480 cells transfected with the mutated pNL4-3 DNAs produced particles with normal protein and RNA content and slightly decreased RT activity. These particles were not infectious. Whereas RT activities of normal and mutant RTs expressed in E. coli were essentially the same, the RNase H activity in mutant RTs was decreased more than 30 fold.
Conclusion. Two conserved aspartic acid residues in RT are associated with RNase H function and are critical for infectivity of pNL4-3.

Th.C.P.104 HIV DETECTION IN PLASMA OF PATIENTS WITH RETROVIR.

Lu, Wei ; Venet, A. ; Tourani, J.M. ; Israel-Biet, D. ; Stern, M. ; Lowenstein, W., Velstein, M. ; Andrieu, J.M. for the Laennec HIV Study Group - Laennec Hospital 42 rue de Sèvres - 75340 PARIS CEDEX 07 - FRANCE.

Measurement of the viral load in HIV disease is crucial for the management of seropositive patients (pts) specially to evaluate their response to current and future therapeutic trials. To assess the HIV production in vivo, we have developed an assay measuring directly cell-free virus in plasma. We cultured plasma (and cells) from 32 HIV+ pts (10 AIDS and 22 seropositive pts with low T4 cell counts) before and 1 month after onset of AZT therapy (20mg/kg) ; 10^6 allogeneic normal T-blasts grown in PHA and IL2 were cultured with 25% vol/vol HIV+ plasma or with 10^6 HIV+PBL in IL2-enriched medium ; supernatants were serially harvested for 30 days ; p24 was assess with an immuno capture assay (Enzacor). Cell cultures were 100% plasma cultures and antigenemia are given in the following table :

	Non-AIDS pts		AIDS pts	
	before AZT	under AZT	before AZT	under AZT
Plasma culture	9 positive →	3 positive	8 positive →	2 positive
" "	13 negative →	2 positive	2 negative →	1 positive
Antigenemia	11 positive →	9 positive	7 positive →	5 positive
"	11 negative →	1 positive	3 negative →	0 positive

These data demonstrate a significant decrease of plasma infectivity under earlier administration of AZT, and suggest that measurement of plasma HIV is a more valuable tool to evaluate the in vivo antiviral activity of chemical compounds than p24 antigenemia. However, since these 2 parameters are not closely linked they are both useful for the management of HIV seropositive individuals.

Th.C.P.105 HTLV 1 ANTIBODY SCREENING IN IV DRUG MISUSERS, HAEMOPHILIACS, HOMOSEXUALS AND BLOOD DONORS IN EDINBURGH, SCOTLAND.

Burns, Sheila M.*; Hargreaves,F.D.*; Yap, P.L.**; Jordan,A.**; Tosswell,J****; Leadbetter,G.***. et al.
*Regional Virus Laboratory, City Hospital, EDINBURGH.
**Scottish National Blood Transfusion Service, EDINBURGH.
***Hepatitis Reference Laboratory, University of Edinburgh.
****Central Public Health Laboratory, LONDON. UNITED KINGDOM

Objective. To test for HTLv 1 antibody levels in three high risk populations and new blood donors in an area where a high proportion of intravenous drug misusers (IVDM) are HIV positive.
Methods. HTLV 1 antibody tests were performed on sera from 302 IVDM, 138 blood product recipients (80 haemophiliac A and 58 other blood disorders), 153 homosexual or bisexual men and 5000 new blood donors using Dupont HTLV 1 ELISA. HIV antibody seropositivity rates in the groups studied were estimated. Confirmatory testing of HTLV 1 antibody was by immunofluorescence (IF) against HTLV 1 infected cells, particle agglutination assay for HTLV 1 (Fujirebio) and immunoblotting.
Results. 1 of 302 IVDMs, 1 of 138 blood product receipients, 0 of 153 homosexual or bisexual men and 1 of 5000 new blood donors were positive by ELISA. Confirmatory testing was undertaken on the single positive IVDM and the individual was negative for HTLV 1 by particle agglutination but positive by IF and immunoblotting. This patient (who is HIV 1 antibody negative) may be infected with a retrovirus other than HTLV 1 or HIV 1. The single positive haemophiliac was of Japanese origin and was possibly infected by Japanese blood or blood products. Results from confirmatory testing are awaited in the single positive blood donor.
Conclusion. HTLV 1 appears in this initial survey not to have significantly infiltrated a population with a high rate of HIV antibody infection, nor in other high risk populations or new blood donors in the same city.

Th.C.P.106 THE KILLING EFFECT OF 65°C TEMPERATURE ON HIV-1 IN DRIED BLOOD; DECONTAMINATION OF LAB INSTRUMENTS/EQUIPMENTS.

Homayoon Farzadegan*, W. Hardy*, K. Qatsha*, B. Tepper*, P. Goldenbaum**, A. Saah*. *The Johns Hopkins School of Hygiene and Public Health, Baltimore, MD; **Becton-Dickinson, Johnston Laboratories, Towson, MD, U.S.A.

OBJECTIVE: To determine the efficacy of 65°C for inactivation of HIV-1. This information is valuable for industrial settings involved in repairing laboratory instruments/equipments contaminated with human blood.
METHOD: HIV-1 (250-500 pg/ml P24) was mixed with normal blood. One tenth of 1 ml HIV-1 inoculated blood was placed on a sterile glass-slide (in duplicate) and air dried at room temperature for 24 hours. Dried blood samples were left in an oven heated to 65°C for 4,8,12,18,24 and 36 hour intervals. After the specified time interval, samples were removed and blood was eluded in 5ml of RPMI. A sterile rubber police spatula was used to ensure removal of blood residues. Eluates were used for HIV-1 isolation using cocultivation with PHA-P treated normal PBMC's ($5X10^6$ cells/ml) in a T25 culture flask in Il-2 containing RPMI culture media and monitored for viral growth.
RESULTS: HIV-1 was isolated from blood samples not heated at 65°C. However, HIV-1 was not recovered during one month of follow-up from any blood samples that were incubated at 65°C for four hours or more.
CONCLUSION: HIV-1 in dried blood does not survive four hours or more at 65°C. This low and safe temperature therefore could be applied for decontamination of laboratory instrument/equipment contaminated with human blood.

Th.C.P.107 FUSION OF SIMIAN IMMUNODEFICIENCY VIRUS (SIV_{mac}) WITH LIPOSOMES AND ERYTHROCYTE GHOSTS.

Larsen, Charles*; Alford, D.*; Young, L.**; Lee, K-D*; McGraw, T.**; and Düzgüneş, N.*.
*University of California, San Francisco, CA, USA; and **California Primate Research Center, Davis, CA, USA.

We investigated the kinetics of membrane fusion between SIV_{mac} and phospholipid vesicles, and the effects of various parameters on this process. SIV was purified by ammonium sulfate precipitation of cell-free supernatant followed by two sucrose density gradient centrifugations, and labeled with octadecyl rhodamine (R18). Fusion was monitored continuously as an increase of fluorescence intensity resulting from the dilution of the probe into target membranes. Ultrastructural analysis of the virus and fusion products was performed by electron microscopy. Viral fusion was strongly dependent upon the liposome composition. Pure cardiolipin (CL) vesicles fused with the virus at a fifty-fold greater rate than pure dioleoylphosphatidylcholine (DOPC) liposomes. SIV fusion with CL/DOPC (3:7) and phosphatidylserine (PS) vesicles was slower than that with pure CL. Calcium or reduced pH greatly enhanced the rate of SIV-CL fusion but did not affect that of SIV-DOPC fusion. SIV also fused with erythrocyte ghosts, and the rate of fusion increased in the presence of calcium or reduced pH. SIV fusion with model membranes is similar in some aspects to that of other lipid enveloped viruses. Our results indicate that SIV can fuse with biological and model membranes lacking the CD4 receptor. This assay system can be used to test inhibitors of the fusion activity of SIV.

Th.C.P.108 MONOCLONAL ANTIBODIES TO HTLV I AND HTLV II GAG PROTEINS.

Haffner-Barrett, Cathy L.,* Bodner, A.J.,* Alexander, S.,* Salahuddin, Z.,** Lipsky, M.,*** and Corrigan, A.*
*Biotech Research Laboratories, Inc., Rockville, MD
**LTCB, National Institute of Cancer, Bethesda, MD.
***National Institute of Health, Bethesda, MD. U.S.A.

Objective. To generate specific and cross-reactive monoclonal antibodies (MoAb) to HTLV I and HTLV II gag proteins.
Methods. Lymphocytes from Balb/c mice immunized with either HTLV I or HTLV II virions were fused with NS-1 myeloma cells in the presence of PEG. ELISA assays were utilized to select cells secreting anti-viral immunoglobulins. Cells were cloned by limiting dilution. ELISA results were confirmed and protein specificity determined by Western Blot and by RIPA. Immunoglobulin subclass was determined by Ouchterlony double diffusion.
Results. MoAbs isolated from HTLV I immunized mice showed the following reactivities: (1) specificity for HTLV I p19, (2) specificity for HTLV I p24, (3) cross-reactive with HTLV I and HTLV II p24, and (4) cross-reactive with HTLV I p19 and HTLV II p22. The HTLV I p19 specific clones recognize two different epitopes: one which reacts with the intermediate proteins and one which recognizes only p19. MoAbs isolated from HTLV II immunized mice were: (1) specific for HTLV II p22, (2) cross-reactive for HTLV I p19 and HTLV II p22, and (3) cross-reactive for HTLV I and HTLV II p24. All MoAbs were of the IgG_1 subclass.
Conclusion. HTLV I p19 and HTLV II p22 share a common epitope. The p19/p22 and the p24 proteins of HTLV I and HTLV II have similar and differing antigenic epitopes.

Th.C.P.109

ADDITIONAL CHARACTERIZATION OF UNUSUAL HUMAN IMMUNODEFICIENCY ISOLATES FROM TWO CAMEROUNIANS. (ANT 70 AND ANT 70 NA)

Bart Vanderborght, L. Brys, M. Vanden Haesevelde, H. Van Heuverswyn, R.J. De Leys. Innogenetics N.V. Antwerpen, Belgium.

Objective: To assess the relationship between isolated ANT 70 and ANT 70 NA and other HIV and SIV strains and to determine the biological properties of the isolates.
Results: Dot-blot hybridization experiments were performed in order to evaluate the relatedness of the isolate ANT 70 to other known human and simian immunodeficiency viruses. Hybridizations were carried out using probes derived from HIV-1 (gag-pol), HIV-2 (pol-env), and ANT 70 (nef-U3). Under nonstringent conditions, crosshybridization was observed between virus types. However, a clear distinction could be made between ANT 70 or ANT 70 NA, and other virus types under stringent conditions. Although ANT 70 and ANT 70 NA have been shown to be indistinguishable by Western blotting or nucleic acid hybridization, biological differences could be demonstrated between the two strains in terms of their preference for certain cell lines.
Conclusions: ANT 70 and ANT 70 NA differ significantly in their nucleic acid homology from prototype HIV-1 and HIV-2 strains, even in relatively highly conserved regions of the genome. The two isolates are highly related to each other but can be differentiated based on biological properties.

Th.C.P.111

DETECTION OF HIV GENOME IN SERONEGATIVE HOMOSEXUAL MEN

Pezzella Mario+; Cordiali-Fei,P.++;Vonesch,N.+; Gentili,E.++ Sturchio,E.+ and Caprilli F.++
+Institute Infectious Diseses, Policlinico Umberto I University of Rome,
++Dermosyphylopatic Institute S. Gallicano, Rome, Italy

Objective. The aim of our investigation was to evaluate the presence of HIV latent infection and HBV genome in peripheral blood mononuclear cells (PBMCs) from 20 asyptomatic homosexual men with multiple sexual partners. All the subjects, non intravenous drug users, were seronegative for anti-HIV antibodies (ELISA test and Western Blot), for HIV antigen and HBsAg. The T4/T8 ratio ranged between 0.75 - 2.25.
Methods. Cytocentrifuged PBMCs were "in situ" hybridized with three probes: 1) an SP 64 plasmid containing the 9 kb SstI-SstI viral insert from lambda BH 10 recombinant clone able to recognise both viral mRNA and proviral cDNA; 2) the whole HBV genome, near 3.3 kb, purified from pAO1 plasmid; 3) the pBR322 plasmid lacking viral insert. The probes were tagged by inserting an antigenic sulfone group in cytosine moieties and visualized by the sandwich immunohistochemical reaction using a specific monoclonal antibody against the sulfone group and an anti-mouse alkaline phosphatase conjugate antibody (Chemiprobe, Orgenics). The controls were performed by HIV non infected and infected H 9 cell culture lines and PBMCs from 20 healthy heterosexual men.
Results. HIV genome sequences were observed in the cytoplasm of mononuclear cells of three subjects as a granular staining and in some cases a mild nuclear positivity was found. The HBV genome was observed also in three cases.
Conclusions. Active homosexual and/or bisexual men are at risk of acquiring HIV infection.

Th.C.P.113

Sodium Pentosan Polysulfate (SP-54), an Anti-HIV Agent Also Exhibits Lymphocyte Proliferative Activity and Synergism with AZT.

Kita Anand, Sanjeev Nayyar, Teresa A. Galvin, Carl R. Merril, Llewellyn B. Bigelow[†], Laboratories of Biochemical Genetics and Clinical Brain Disorders[†], National Institute of Mental Health, Saint Elizabeths Hospital, Washington, DC U.S.A.

Objective. Sodium pentosan polysulfate (SP-54) was studied for its antiviral action against HIV-1 and was compared with dextran sulfate (DS) and AZT.
Methods. Drug responses on the production of HIV-1 in normal human peripheral mononuclear cells were tested by reverse transcriptase (RT) assay, p24 antigen test and p24 radioimmunoassay.
Results. More than 90% of virus replication was inhibited with 5.0 mcg/ml of SP-54. Direct inhibitory effect of SP-54 was also observed on the HIV reverse transcriptase reaction in vitro. No toxicity was observed with SP-54 on PMNC cultures. In fact, it had proliferative effect on uninfected PMNC and protective effect on infected PMNC cultures at concentrations of 0.1 to 10.0 mcg/ml. In addition, SP-54 showed profound synergism with AZT. In the presence of 25 and 100 nM AZT, 2.0 mcg/ml of SP-54 reduced HIV-1 replication 110- to 176-fold as compared to 3- to 16-fold decrease in the presence of either drug.
Conclusions. SP-54, owing to its anti-HIV-1 activity, nontoxic nature, lymphocyte proliferative activity and synergism with AZT could prove to be a valuable agent in the chemotherapeutic intervention of AIDS.

Th.C.P.110

EXPRESSION OF THE GAG-POL GENE PRODUCTS OF HUMAN IMMUNODEFICIENCY VIRUS BY RECOMBINANT VACCINIA VIRUS VECTOR

Shioda, Tatsuo; Hirose, K.; Sawada, H.; and Shibuta, H.
Institute of Medical Science, University of Tokyo, Tokyo, Japan.

OBJECTIVE: To understand the molecular mechanisms of virion assembly and processing of the gag precursor of HIV. METHODS: The gag and pol genes of HIV1 were inserted so as to be driven by the 7.5 K promoter in the thymidine kinase gene of vaccinia virus strain WR by the standard procedure.
RESULTS: In the lysates of CV-1 and SW480 cells infected with the recombinant vaccinia virus (RVV) carrying the entire gag-pol region, the precursor gag protein was almost exclusively detected by immunoblot analysis using serum from an AIDS patient. However, in the culture fluids of infected SW480 cells, but not of infected CV-1 cells, we could clearly detect reverse transcriptase (RT) activity, even when the replication of vaccinia virus was suppressed by cytosine arabinoside. The highest RT activity was found at a density of 1.16 g/ml and this fraction was revealed to contain mainly the cleaved gag proteins by immunoblot analysis, suggesting that particles containig the HIV RT and the cleaved gag proteins were released from infected SW480 cells. The corresponding fraction prepared from the culture fluids of SW480 cells infected with another RVV carrying only the gag gene contained exclusively the uncleaved gag precursor and lacked the RT activity, confirming that the processing of the gag precursor was mediated by the HIV protease encoded in the pol gene. Electron microscopic exanamination is now under way. CONCLUSION: Our results showed that only the gag gene products are sufficient for particle production and suggested that the particle formation is necessary for efficient processing of the gag precursor.

Th.C.P.112

A METHOD FOR QUANTITATING INFECTIOUS HIV PARTICLES

Tjøtta, Enok and Grinde, B.
Department of Virology, National Institute of Public Health
Oslo, Norway.

Objective. To develope a method for determining the number of infectious HIV particles in various preparations.
Method. MT4 cells were incubated with the preparation containing HIV particles for 1 h. The cells were then mixed with a molten solution of agarose in a cell medium. The agarose was placed in the refrigerator for rapid solidification. Extra medium was added on top of the gel and the tubes incubated for four days with one medium change. The gels were then melted by heating, mixed with a salt solution and the cells rescued by centrifugation. After fixing, the cells were stained by immuno-fluorescence using an anti-HIV antiserum. The relative number of fluorescent cells were counted.
Results and Conclusion. Culturing the infected cells in an agar gel seemed to inhibit the transfer of virus between cells. The number of HIV positiv cells after the incubation should therefore reflect the concentration of infectious HIV particles in the original preparation. If the cells had been cultured without a gel, some cells would be expected to present antigen due to secondary infection. The present method is faster than traditional plaque assay.

Th.C.P.114

VIRAL GENE EXPRESSION ASSESSED BY PCR IN HIV-1 INFECTED H9 CELLS

Hewlett, Indira, Ruta, M., Geyer, S.J., Hawthorne, C. and Epstein, J.S.
Food and Drug Administration, Bethesda, MD., U.S.A.

Objective. To study early events of viral gene expression in HIV-1 infected cells by a sensitive gene amplification technique, polymerase chain reaction (PCR).
Methods. H9 cells were infected with HIV-1 (10^6 infectious units/ml). At various times after infection (3,6,18,24,48,72 and 144 hr), high molecular weight DNA and RNA were isolated. Virus-specific DNA and RNA were detected by co-amplification of primer pairs to gag, env, tat and nef regions of the viral genome using PCR. Reverse transcriptase (RT) activity was measured by direct assay of cell culture supernatants.
Results. Virus-specific sequences were first detected in genomic DNA of H9 cells 3 hrs. after HIV-1 infection, thereafter, these sequences increased in copy number. Synthesis of viral-specific RNA was detected at 6 hrs. after infection. Extracellular RT activity increased 35-fold, to 0.75 pmol TTP/hr/20 ul between 3 and 6 days after infection.
Conclusion. Results indicate that virus-specific DNA became integrated into host genome rapidly after HIV-1 infection, followed several hours later by synthesis of viral RNA's. Release of virion, signalled by increased extracellular RT, was delayed between 3 and 6 days. These results demonstrate that PCR is a useful technique to evaluate early events in replication of HIV-1 in target cells such as lymphocytes and macrophages.

Th.C.P.115 PURIFICATION AND ANALYSIS OF THE HTLV-I ENVELOPE GLYCOPROTEIN gp46 USING AN ANTI-CARBOXYL-TERMINAL SYNTHETIC PEPTIDE SERUM.

Lillehoj, Erik; Nguyen, A.; Tai, C.; Alexander, S.
Biotech Research Laboratories, Inc., Rockville, MD 20850, USA.

Objective. The objective was to isolate gp46 from HTLV-I transformed HUT102 cells by immunoaffinity chromatography.
Methods. A rabbit antiserum against a synthetic peptide corresponding to the carboxyl-terminus of gp46 (LPPFSLSPVPTLGSRSRR) was prepared and analyzed for reactivity with the native gp46 and precursor gp61 proteins by ELISA, Western blot and RIPA assays. An affinity column was used to purify gp46.
Results. The anti-peptide serum reacted with proteins with apparent molecular weights of 46,000 on HTLV-I and HTLV-II viral lysate Western blot strips. The specificity of this reaction was established by inhibition with the homologous but not an irrelevant peptide. Removal of N-linked carbohydrates with endoglycosidase F resulted in a decrease in molecular weight from 46,000 to 31,000. RIPA analysis using [35S]methionine labeled HUT102 cell lysate revealed specific reactivity with the envelope precursor gp61 in addition to a smaller protein of approximately 30,000 daltons. gp46 was purified by immunoaffinity chromatography and shown to be reactive with sera from HTLV-I infected patients as well as a monoclonal anti-HTLV-I gp46 antibody but not with sera from uninfected individuals or monoclonal anti-HTLV-I gag (p19, p24) antibodies. Faint reactivity of the gp46 preparation with an antiserum against uninfected T lymphocytes revealed minor contamination with cellular proteins.
Conclusion. HTLV-I gp46 can be purified using an anti-peptide serum in a form suitable for evaluating envelope-enriched ELISA and Western blot assays.

Th.C.P.116 BIOLOGICAL HETEROGENEITY AMONG HIV-1 ISOLATES

Moore, Barbara E., Hart, Audrey R., and Cloyd, Miles W.
Department of Microbiology, The University of Texas Medical Branch, Galveston, TX 77550 USA.

Objective: To biologically characterize HIV-1 isolates having variable tropisms and cytopathogenicity.
Methods: The infection kinetics of 14 independent HIV-1 isolates were monitored in 8 cell lines. Viral replication was characterized with respect to RT activity, p24 production, and cell growth and viability.
Results: In the absence of preexisting transactivator activity, HIV-1 isolates spread slowly in most cell cultures requiring from 8-14 days to achieve infection in 100% of the cell population. The viruses varied in their tropisms, with the degree of susceptibility of CD4-positive cell lines to infection varying as much as 100,000-fold. One isolate, HIV-1_{TP1}, infected the promonocytic cell line, THP-1, and T cell lines equally well; but it did not readily infect the HL-60 promyelocytic cell line. RT activity was an unreliable measure of viral replication. Some isolates yielded high RT, while others were consistently low. In addition, RT was always low in some cell lines even though high titers of infectious virus were produced. HIV-1 isolates varied in their ability to kill and/or fuse cells, however most isolates killed cells without syncytia formation.
Conclusions: HIV-1 isolates demonstrate considerable heterogeneity in their biological properties. Cell tropism, replication, and CPE within a given cell may well be important parameters of virulence. The findings of this study should form a framework from which HIV genome sequence information may eventually be correlated with biological function.

Th.C.P.117 CLONAL HETEROGENEITY OF HIV-1 ISOLATES IN U-937 CELLS.

Boulerice, Francois[*]; Bour, S[*]; Geleziunas, R.[**]; and Wainberg, M.A.[*]
[*]Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, Department of Experimental Medicine and
[**]Department of Immunology and Microbiology, McGill University, Montreal, Quebec, Canada.

Clones of U-937 cells were derived from a chronically-infected population by limiting dilution and micro-manipulation. We studied the expression of HIV-1 by immunofluorescence and reverse transcriptase assays in six of these clones. Four of them showed presence of the p24 viral antigen that correlated with normal mRNA expression and reverse transcriptase activity in the supernatants. These virus-containing supernatants were inoculated onto other cell types and were shown to differ in infectiousness. Western blot analysis revealed structural differences at the level of viral antigens which could account for a defect in viral budding and infectivity. The results clearly show heterogeneity of isolates recovered from U-937 clones and raise the question as to whether the expression of HIV-1 is influenced by the innate biological characteristics of these clones.

Th.C.P.118 A RAPID, DIRECT ASSAY FOR REVERSE TRANSCRIPTASE ACTIVITY IN HIV-INFECTED CELL CULTURE SUPERNATANTS.

Geyer, Sharon J. and Epstein, J. S.
Food and Drug Administration, Bethesda, MD, U.S.A.

Objective.To develop a simple, rapid and sensitive assay for reverse transcriptase (RT) activity in HIV-infected cell culture supernatants.
Methods.The RT microassay reported by Spira et al. (J.Clin.Micro. 25:97,1987) was miniaturized and conditions for trapping the ^{3}H-products on glass fiber and DEAE filter mats were optimized for rapid collection and counting on a flatbed scintillation counter. Briefly, 20ul of culture supernatant was transferred directly to a 96-well microtiter plate and virus coats were solubilized with 5ul buffer including 30% glycerol and 0.5% Triton X-100. 25ul containing 5uCi ^{3}H-thymidine triphosphate (TTP, 20Ci/mmol, NEN), 0.45ug poly(rA)oligo(dt)$^{12-18}$ (Pharmacia) and 10mM $MgCl_2$ were added to wells and incubated at 37°C. Reaction products were precipitated with tRNA (Sigma) buffer and 10% TCA and transferred to mats using a cell harvester (LKB). Mats were counted in a flatbed scintillation counter (Betaplate, LKB).
Results.The RT reaction was linear over a 100-fold range of RT concentrations during 4 hr incubation at 37°C. 20ul of supernatant from 10^6 HIV_{IIIB}-infected H9 cells incorporated 1.1 pmol TTP/hr, 3.5 times the activity reported in the micromethod. RT activity in supernatant of 10^5 H9 cells/ml rose 35-fold, to 0.75 pmol TTP/hr, 6 days after infection with approximately 10^4 infectious units of HIV_{IIIB}. Completion of RT measurements in one 96-well plate required about 3 hr, while each additional plate added 20 min to total processing time.
Conclusion.The procedure described for measuring RT activity in cell culture supernatants does not require isolation or concentration of virus and represents a simple, sensitive and rapid assay for HIV replication *in vitro*.

Th.C.P.119 SIMULTANEOUS DETECTION OF HIV-1 AND HTLV-1 INFECTIONS BY CO-AMPLIFICATION USING PCR

Ruta, Martin, Hewlett, I.K., Hawthorne, C.A., and Epstein, J.S.
Food and Drug Administration, Bethesda, MD., U.S.A.

Objective. To detect in the same PCR reaction, the presence of multiple viral infections.
Methods. Genomic DNA isolated from HIV-1 (H9/HTLV-IIIB) or HTLV-1 (MT-2) infected cells was used as the template for gene amplification. PCR was performed in the presence of primer pairs to the gag and env genes of HIV-1 and the pol region of HTLV-1 primers were optimized for conditions of equal sensitivity.
Results. PCR performed by co-amplification of the HIV-1 gag and env regions was positive for both gene sequences in 21/21 high risk samples and 0/11 negative controls. In addition PCR performed on mixed genomic DNAs (H9/HTLV-IIIB and MT-2) resulted in specific detection of each of the amplified targets with comparable sensitivity (20-40 gene copies each).
Conclusion. Using co-amplification of multiple gene sequences it is possible to simultaneously detect and confirm the presence of HIV-1 in clinical samples. In reconstitution experiments the same method has been used to simultaneously detect HIV-1 and HTLV-1 predicting another clinical application.

Th.C.P.120 VARIABILITY OF HIV-1: COMPUTER ANALYSIS OF DATA BASE.

Hirofumi Doi, Division of Biological Information Science,
IIAS-SIS, FUJITSU Ltd., Shin-kamata, Ohta-ku, Tokyo 144, Japan.

Objective. The activity of the reverse transcriptase (RT) depends on Mg ion, and the ionic strength around RT may be very strong and may force the nucleic acid sequence to have a specific conformation near RT. The conformation may depend on the context of the nucleic acid sequence. I analyzed the data base (Los Alamos, 1988) with computer to examine whether the variability of the env gene depends on the context or not.
Methods. The viruses in the data base were divided into four groups; New York, WMJ, Haiti which contains sf2, cdc and rf, and Africa. The variability was considered within each group, and to examine the context dependency the variability of a sextuplet composed of purine (r or R) or pyrimidine (y or Y) was considered. When only one strain in a group was mutated at the same point of the env gene sequences, this mutation was counted to calculate variabilities of sextuplets. The variability of a sextuplet in a group was defined as:

$$\frac{\text{the sum of counted point mutations at the 2nd, 3rd and 4th bases of the sextuplet in the group}}{\text{the frequency of appearance of the sextuplet in the consensus env gene sequence of the group.}}$$

Results. The RRR in the sextuplets rRRRrr, rRRRry and rRRRyr corresponds to the amino acids which have polarity and the mutation of these amino acids may be very advantageous to escape from the immune system of host. If the mechanism causing variation was random, these sextuplets showed the same high variabilities. The variabilities of rRRRry and rRRRyr were, however, the highest ones in the 64 possible sextuplets, but that of rRRRrr was at about the average. This was common to the four groups. There were sextuplets which showed similar variabilities among the four groups like rRRRry and rRRRyr, and some other sextuplets showed distinct variabilities among the four groups. For example, that of rRRYyr decreased from the Africa group to the New York group.
Conclusion. These strongly suggest that the variability of the env gene depends on the context of the nucleic acid sequence (therefore on the conformation), and depends on RT of each group.

Th.C.P.121 DEVELOPMENT OF A NOVEL QUANTITATIVE ASSAY TO STUDY MEMBRANE FUSION MEDIATED BY gp120/gp41

Nelson, M. Bud; Zhang, Y.-H.; Rekosh, D. and Hammarskjöld, M.-L.
Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

A single vector (pSVSX1) expressing the tat, rev and envelope proteins of HIV-1 was used to develop a quantitative fusion assay. This assay is based on the ability of the tat protein to transactivate the HIV LTR. CD4+ cells are transfected with a plasmid (LTR-CAT) in which the LTR is linked to the chloramphenicol acetyl-transferase gene and at the same time CV-1 cells are transfected with pSVSX1.Twenty-four hours later these cells are mixed and after an additional twenty-four hours of incubation the cells are harvested, extracted and assayed for CAT activity. If fusion takes place, the tat protein produced in the CV-1 cell is able to transactivate the LTR CAT. This is the only mechanism by which transactivation occurs in this system, since control experiments have ruled out leakage of tat from transfected cells and transactivation by uptake into the CD4+ cells. The sensitivity of this assay permits it to be performed using only a small number of cells in multi-well dishes. This assay has been used to analyze fusion inhibition by specific antisera and peptides.

Th.C.P.122 EXPRESSION AND CHARACTERIZATION OF HIV-1 ENVELOPE PROTEINS SYNTHESIZED FROM A SV40 VECTOR

Hammarskjöld, Björn; Nelson, M.B.; Hammarskjöld, M.-L.; and Rekosh, D.; Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

We have used an SV40 late replacement vector system to express HIV-1 envelope proteins in COS cells. One construct produces gp160 which is efficiently processed to gp120 and gp41. Fusion assays utilizing transfected cells and CD4 expressing Hela cells indicate that functional env proteins are inserted into the plasma membrane of the transfected cells. Approximately one third of the gp120 produced is found in the medium. This plasmid was modified to produce a soluble form of gp120 which is efficiently secreted into the culture medium. Other truncated forms of the envelope protein have also been made. We have started a systematic analysis of these proteins with regard to kinetics of cleavage and glycosylation, transport and oligomerization.

Th.C.P.123 PURIFIED REVERSE TRANSCRIPTASE (RT) FROM HIV-1, HIV-2 AND EIAV SHARE STRUCTURAL AND IMMUNOLOGIC PROPERTIES

DeVico, Anthony*, Copeland, T.**, Oroszlan, S.**, Montelaro, R.***, Gallo, R.****, and Sarngadharan, M.G.* *Bionetics Research, Inc., Rockville, MD, **NCI-FCRF, Frederick, MD, ***LA State Univ., Baton Rouge, LA ****NCI, NIH, Bethesda, MD/U.S.A.

Objective: To determine if sequence homology among the RT proteins of the lentiviruses is reflected in common structural and immunologic properties.
Methods: A synthetic peptide derived from a C-terminal portion of HIV-1 RT which is conserved in all lentiviral RTs was used to raise rabbit monospecific sera. Purified IgG was tested for RT inhibitory activity and as immunoaffinity adsorbent to purify RT from HIV-2 and EIAV.
Observations: Anti-peptide IgG directly inhibited RT from HIV-1, HIV-2 and EIAV RT and it provided a good chromatography matrix to purify RT from HIV-2 and EIAV. RT activity was associated with a pair of proteins - p68/p55 for HIV-2 and p66/p51 for EIAV. Sera of HIV-2 infected individuals had anti-RT antibody; EIAV-infected horses did not.
Conclusions: The RTs of HIV-1, HIV-2 and EIAV share structural similarities, being comprised of two associated proteins. However, high immunogenicity seems to be a feature of human lentiviral RTs. The broadly inhibitory nature of the antibody suggests that the peptide sequence represents a portion of the RT active site.

Th.C.P.124 CLONING, PRELIMINARY CHARACTERISATION AND EXPRESSION OF GENE FRAGMENTS OF A EUROPEAN HIV-2 ISOLATE (ANT53).

Parker, David; Vanden Haesevelde M.*; Vanderborght B.*; Driver, A.; Jarvill, M.; and Highfield P Wellcome Diagnostics., Beckenham, Kent, U.K. * Innogenetics, Kronenburgstraat 45, 2000 Antwerpen, Belgium.

A Belgian AIDS patient, who had never visited Africa, was found to have a Western blot profile consistent with an HIV-2 infection. An HIV (designated ANT53) was isolated from this patient and adapted to culture. An HIV antigen capture test on culture supernatants indicated that this was indeed an HIV type 2 (Vanderborght *et al*, 1988 Eur J Clin Microbiol Infect Dis 7: 816-8)
OBJECTIVES. To clone and sequence this isolate to determine its relationship to the African HIV-2 prototype ROD and to express ANT53 genes in heterologous systems to obtain reagents for further research.
METHODS. Viral RNA from infected cell cultures was used to prepare cDNA clones either by standard methodology or by the use of PCR technology. Specific gene products were then expressed in prokaryotic (*E. coli*) and eukaryotic (insect cell) systems and analysed immunologically.
RESULTS. Clones containing the major genes were obtained and preliminary sequence data has shown that ANT53 is an HIV-2 isolate and is distinct from HIV-2 ROD; the homology is between 70-90% at the amino acid level depending upon the particular gene compared. *Env* and *gag* polypeptides have been expressed both in *E. coli* and baculovirus systems and are reactive with anti-HIV-2 sera.
CONCLUSION. ANT53 is an HIV-2 isolate related to but distinct from the African prototype ROD. Recombinant viral gene products will be useful as research tools and as potential diagnostic and vaccine reagents.

Th.C.P.125 KINETICS OF APPEARANCE AND SPECIFICITY OF NEUTRALIZING ANTIBODIES IN PATIENTS WITH PRIMARY HIV INFECTION.

Albert, Jan*,**; Ljunggren, K**; Nagy, K***; Abrahamsson, B*; Fenyo, E M**.
*National Bacteriological Laboratory, Stockholm, Sweden.
**Karolinska Institute, Stockholm, Sweden.
***Hungarian Academy of Sciences, Budapest, Hungary.

Objective. To study the appearance of virus neutralizing antibodies in patients with symptomatic primary HIV-1 infection. To establish if these antibodies play a role 1) in elimination of the initial viremia; 2) in selection for the development of antigenically distinct HIV-1 strains in the infected individual.
Methods. Sequential HIV isolates and serum samples were obtained from four patients during and after primary HIV infection. The neutralizing capacity of the sera from one individual was tested against sequential virus isolates from the same and other invividuals.
Results. Preliminary results show that HIV neutralizing antibodies develop early after infection. The initial antibody response is strain-specific, but widens with time to include several strains.
Conclusions. The results will be important in understanding early events in HIV-1 infection and in vaccin studies.

Th.C.P.126 EVALUATION OF THREE METHODS FOR HIV DETECTION IN CULTURE IN HAEMOPHILIA A PATIENTS

[1]S.Rebus, [3]D. Beatson, [1]J. Stewart, [3]C.M. Steel, [2]R.J.G.Cuthbert, [2]C.A.Ludlam
[1]J.F. Peutherer.
1.Department of Bacteriology, University of Edinburgh, 2.Department of Haematology,Royal Infirmary of Edinburgh, 3. MRC Cytogenetics unit.UNITED KINGDOM

Objective. To evaluate 3 methods for HIV detection in culture in HIV antibody positive haemophilia A patients.
Methods. PBMCs from 40mls of heparinised blood were seperated on a Ficol-hypaque gradient. One third of the cells were cultured in RPMI 1640 in the presence of FCS, IL-2 and PHA. On the remaining cells a panning method was used for CD8$^+$ cell depletion. Half of the seperated PBMCs from the CD8$^+$ depleted non adherent fraction were co-cultured with the cell line C-8166 in RPMI 1640 with FCS, IL-2 and PHA. The other half was co-cultured with PHA stimulated CD4 enriched PBMCs from a know HIV negative donor. The 3 cultures were harvested at weekly intervals, supernates were tested for the presence of p24 antigen using an antigen capture assay (Dupont). The panning efficancy was checked by flow cytometry (Simultest. Becton Dickinson).
Results. Flow cytometry showed that the panned PBMC fractions contained less then 10% CD8$^+$ cells. Six out of 15 patients were investigated,1 has consistently yielded a positive virus culture, 1 has had a positive culture on one occassion and 4 have been negative over a period of 2 years. The results are presented in the table below:-

CDC Status	Number of patients	Unpanned culture	co-culture of panned PBMCs with:-	
			CD4$^+$ enriched	C8166
II	2	-	2	1
IV A	1	1	1	1
IV C-2	2	-	1	1
IV C-1	1	-	1	1

Conclusion. Co-cultivation of CD8$^+$ depleted PBMCs is a more sensitive method for HIV detection then simple culture of PBMCs and the addition of normal CD4$^+$ cell may promote virus detection.

* FCS Foetal calf serum.

Th.C.P.127 RECOGNITION OF ANTIBODIES IN HIV-1 POSITIVE SERA BY SYNTHETIC PEPTIDES DERIVED FROM DIFFERENT VIRAL PROTEINS

Mach,O.+,Reiniš,M.+,Kamínková,J.+;Vacek,Z.++;Vandasová,J.+++,
Krchnák,V.++++.
+Institute of Molecular Genetics,Praha,Czechoslovakia,
++University Childrens Hospital,Praha,Czechoslovakia,
+++Hygienic Service,Praha,Czechoslovakia,
++++Léčiva-Pharmaceuticals,Praha,Czechoslovakia.

Objective.To analyse immune response against different epitopes in HIV proteins.
Methods.The peptides were selected from the proteins encoded by gag,pol,env and tat genes and were synthesized by the solid-phase method.Reactivity of peptides with HIV-1 positive sera was monitored by ELISA.The presence of antibodies against HIV was tested by Abbott and Wellcome kits.Simultaneously a T-cell analysis was carried out.
Results.It was found that antibodies against some epitopes of viral proteins were present in all sera tested,but antibodies against other epitopes were present only in a few sera.
Conclusion.The formation of antibodies against .. viral proteins is induced mainly by some epitopes of p24 and gp41.

Th.C.P.128 MEASUREMENT OF ANTIBODY TO HIV1 REVERSE TRANSCRIPTASE

Clive Loveday*; Williams,H*; Tedder,R*; Weber,J**; Weller,I*
*University College and Middlesex Medical School,London,
and **The Royal Postgraduate Medical School,London,United Kingdom.

Objective. To evaluate 2 ELISA assays for measurement of anti-RT activity and determine changes in antibodies to RT in HIV infection.
Methods. Recombinant HIV1 RT@antigen(RT,p66/p51)was adsorbed onto the solid phase.Serum samples were incubated overnight before addition of (sequential assay),or together with(simultaneous assay)alkaline phosphatase labelled RT antigen.Wells were washed and enzyme activity determined by an enzyme amplification method.
Results. All blood donor controls(859)were unreactive in both assays; of 182 anti-HIV1 positive sera 177 were reactive in the sequential assay and 182 in the simultaneous assay.Lower dilutions of seropositive controls were detected in the simultaneous assay than the sequential assay,but the latter produced more consistent concentration/response curves for quantitative studies.Four of 20 anti-HIV2 sera had anti-RT reactivity.
Initial studies of 223 patients during seroconversion showed no anti-RT activity prior to seroconversion to other HIV1 antigens.Samples from 20 seronegative homosexual partners of PGL or AIDS patients followed for >4years had no anti-RT activity detected.Data is also presented on changes in anti-RT during progression of HIV disease(123 patients).
Conclusion. Using recombinant HIV1 RT,ELISA assays have been developed with high specificity and sensitivity for qualitative and quantitative measurement of anti-RT activity in patients throughout HIV disease.
@(Wellcome Diagnostics,Beckenham,United Kingdom)

Th.C.P.129 COMPLEMENT RECEPTOR TYPE 2 (CR-2) IS A RECEPTOR FOR *IN VITRO* COMPLEMENT-MEDIATED, ANTIBODY-DEPENDENT ENHANCEMENT (C'-ADE) OF HIV-1 INFECTION.

W. Edward Robinson, Jr., D. C. Montefiori, and W. M. Mitchell.
Dept. of Pathology, Vanderbilt University, Nashville, TN 37232 USA.

Objective: To determine the receptors required for complement-mediated, antibody-dependent enhancement (C'-ADE) of HIV-1 infection *in vitro*.
Methods: Two murine monoclonal antibodies (mAb) to CR-2 (Ortho Diagnostics, Becton-Dickinson) and seven mAb to CD4 (Ortho Diagnostics) were tested in an MT-2 cell microtiter infection assay for anti-HIV-1, anti-fusion, and anti-C'-ADE activities.
Results: Murine anti-CR-2 mAb, OKB7, but not Becton-Dickinson anti-CR-2 blocked C'-ADE of HIV-1 infection *in vitro*. Neither mAb blocked HIV-1 fusion or infection in the absence of C'. Murine mAb to CD4 had 50% neutralizing activities at the indicated concentrations (Table):

Anti-	OKT4 µg/ml	OKT4A µg/ml	OKT4B µg/ml	OKT4C µg/ml	OKT4D µg/ml	OKT4E µg/ml	OKT4F µg/ml
C'-ADE	3.4	.06	<0.4	64	2.2	22	>55
HIV-1	1.7	0.2	0.4	32.0	2.8	21.7	>55
fusion	6.8	0.4	1.6	>64.0	2.8	10.9	55

Conclusion: Murine mAb to CD4 blocked HIV-1 infection, C'-ADE, and cell fusion while a murine mAb to CR2 receptor blocked C'-ADE of HIV-1 infection *in vitro*, thereby implicating CR2 and CD4 receptors in C'-ADE of HIV-1 infection.

Th.C.P.130 PROCESSING OF THE HIV-1 GAG-POL PRECURSOR PROTEIN

Karacostas, Velissarios* and Moss, B.
Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, USA, *Howard Hughes Medical Institute-NIH Research Scholar.

Objective. To study the processing of the full-length HIV-1 gag-pol precursor protein.
Methods. Oligonucleotide-directed mutagenesis was used to place the gag and pol genes in the same translational reading frame. The modified gene was then incorporated into vaccinia virus and expressed in mammalian cells. Unlabelled and metabolically labelled polypeptides were identified by Western blot and immunoprecipitation, respectively.
Results. Reverse transcriptase activity and polypeptides that rected with HIV-1 specific antisera were detected in cells infected with the recombinant vaccinia virus. At the earliest times, the size of the predominant polypeptide(approximately 160 kDa) was consistent with it being the full-length gag-pol precursor. At late times, the predominant polypeptides corresponded to mature gag and pol products (p17, p24, p32 and p66). Other intermediate size polypeptides (-130, 100, 90, 55 and 41 kDa) appeared transiently. Monospecific antisera and labelling with ^{3}H-myristic acid were used to further characterize the precursor-product relationships. Inoculation of animals (mice and rabbits) with the recombinant vaccinia virus led to the production of antibodies to p17, p24 and p66.
Conclusions. The putative full-length gag-pol precursor polypeptide was synthesized by recombinant vaccinia virus and processed through discrete size intermediates into mature and enzymatically active proteins.

Th.C.P.131 Double reactive sera for HIV1 and HIV2 antibodies and HIV variant strain from West Africa.

SIMON, François*; MAS,S*; DAZZA,MC*; COURGNAUD,V**; MATHERON,S***; BRUN-VEZINET,F*.
*Laboratoire de Virologie, Hopital Bichat-Claude Bernard, Paris France. **Faculte Necker, Paris, France. ***Maladies Infectieuses, Hopital Bichat-Claude Bernard, Paris, France.

Objective:To study by RIPA and synthetic peptides West African sera showing a double reactivity on HIV1 and HIV2 Elisa and WB assays.
Methods : 9 sera were collected from patients (CDC group II,III) originating from Ivory Coast (n=3) and Ghana (n=6). These sera showed by WB (Diagnostics Pasteur) high and equal reactivity on all the glycoproteins of HIV1 and HIV2 (HIV1: gp160, gp120, gp41 ; HIV2: gp140, gp125, gp36). These sera were studied by RIPA (CEM-HIV1$_{Bru}$, CEM HIV2$_{ROD}$) and by dot using transmembrane synthetic peptides (Diagnostics Pasteur). A quantitative evaluation was done by dilution titers and inhibition curves using these peptides on coated microplates.
Results : Eight out of the 9 sera demonstrated by RIPA a strong reactivity on the gag-pol-env products of HIV1 and HIV2, and high and equal reactivity on both HIV1 and HIV2 peptides. Three sera had a 10 time higher antibody (Ab) titer on HIV1 than on HIV2 peptides and 2 other sera had 5-10 fold higher Ab titer on HIV2 than on HIV1 peptides. Three other sera, collected from Ghanaian patients, had equivalent titers on HIV1 and HIV2 peptides with equivalent inhibition curves.
The last serum collected from a Ghanaian woman (CDC group II) was equally reactive on both peptides and had the caracteristic to react by RIPA and WB on the envelope antigens of both HIV1 and HIV2 but only on the p24 HIV1 gag protein without any reactivity on p26 HIV2 gag protein. A cytopathic HIV strain was isolated from PBL. Characterization of this isolate (hybridization) will be presented as well as PCR on fresh PBL.
Conclusion : The double reactive sera could be interpreted as a double infection (as previously described) or as a geographical variation in HIV strains.

Th.C.P.132 FREQUENT ISOLATION AND MOLECULAR IDENTIFICATION OF HUMAN T-CELL LEUKEMIA VIRUS TYPE-2 (HTLV-2) IN THREE U.S. POPULATION CENTERS.

Gore, Ira*; Snyder, T.L.*; Decker, W.D.*, Hahn, B.H.*; Parks, E.S.**; Weiss, S.H.***; Shorty, V.J.****; Parks, W.P.**; Blattner, W.A.*****; and Shaw, G.*
*University of Alabama at Birmingham, Birmingham, Alabama, USA; **University of Miami School of Medicine, Miami, Florida, USA; ***Medical College of New Jersey, Newark, New Jersey, USA; ****Desire Treatment Center, New Orleans, Louisiana, USA; *****National Institutes of Health, Bethesda, Maryland, USA.

Human T-cell leukemia virus type-1 (HTLV-1) is endemic in Japan, the Caribbean, and southeastern United States where it is etiologically linked to adult T-cell leukemia. HTLV-2, a related but phylogenetically distinct human leukemia virus, has been found only sporadically and is associated with a T-cell variant of hairy cell leukemia. Recent serologic surveys of U.S. intravenous drug abuse (IVDA) populations have been interpreted to show that substantial proportions (30-50%) of these individuals are infected with HTLV-1, but the methodology employed in these studies could not distinguish HTLV-1 from HTLV-2. We cultured peripheral blood lymphocytes (PBL) from twenty "HTLV-1" seropositive subjects from New Orleans (10), Newark (1), and Miami (9). The 11 subjects from New Orleans and Newark were black IVDA and the 9 from Miami were from renal dialysis and general blood donor populations. Southern blot hybridization restriction enzyme pattern analysis (SB/RE) and polymerase chain reaction amplification (PCR) were used to identify unambiguously HTLV-1 and HTLV-2 DNA sequences in cultured and uncultured PBL specimens. 14 of 20 PBL cultures were positive by SB/RE for HTLV-2 alone, 3 of 20 were positive for HTLV-1 alone, and 2 of 20 PBL cultures were positive for double infection with both HTLV-1 and HTLV-2. PBL cultures positive for HTLV-2 and/or HTLV-1 by SB/RE were also positive by PCR, but PCR detected one additional double HTLV-1 and HTLV-2 infection and one additional HTLV-2 infection. Using SB/RE and PCR techniques on cultured and uncultured specimens, a total of 17 HTLV-2 and 6 HTLV-1 infections were detected in the 20 subjects studied. This study is the first to demonstrate conclusively that HTLV-2 is a common infection in selected populations in different U.S. cities and that some individuals are coinfected with both HTLV-2 and HTLV-1. The high prevalence of HTLV-2 in certain populations has important implications concerning potential clinical sequelae, heightened risk to the blood supply, and the origin, evolution, and natural history of human retroviral infections.

Th.C.P.133 QUANTITATIVE HIV BLOOD CULTURES.

Redfield, Robert*; Fowler, A.**; Oster, C.*; Burke, D.S.*; and the Walter Reed Retrovirus Research Group
*Walter Reed Army Institute of Research, **SRA Technologies, Inc., Washington, D.C., U.S.A.

Objective. Quantitate the minimum number of patient peripheral blood mononuclear cells (PBMC's) required to isolate HIV in culture.
Methods. PBMC's from 12 staged HIV seropositive patients were obtained by Ficoll-Hypaque separation of heparinized blood. Serial ten-fold dilution of cells ($3x10^6$ to $3x10^2$) were inoculated into cultures of PHA and IL-2 stimulated normal donor target PBMC's. Culture fluids were monitored weekly for 6 weeks for HIV p24 antigen.
Results.

Walter Reed Stage	N patients	Minimum # cells for positive
1 - 2	3	10^4*, 10^4, 10^3*
3 - 4	3	10^5*, 10^4, 10^4
5 - 6	6	10^4*, 10^4, 10^4, 10^3*, 10^2*

HIV was also isolated in cultures from plasma from 5 to the 12 patients (* noted above). Rapid appearance of antigen (≤7 days) in cultures using $3x10^6$ patient cells correlated significantly ($p < 0.05$) with a high titer of circulating infected cells (≥1 in $3x10^3$) and with plasma viremia, and possibly ($p = 0.11$) with stage of illness.
Conclusion. Culture-positive blood from HIV patients contains approximately 100 infected cells per cm^3, with a range from 10 to 10,000 infected cells per cm^3.

Th.C.P.134 A HOST-RANGE MUTANT OF HIV WHICH CAN INFECT FIBROBLAST-LIKE CELLS DERIVED FROM HUMAN BRAIN.

Takeuchi, Yasuhiro and Hoshino, H.
Gunma University, Maebashi, Gunma, Japan

Objective. It is not understood well what type of cells in the brain and what type of HIV have participated in the development of neurological disorders induced by HIV. In this study, we analyzed a mutant HIV which can infect fibroblast-like cells derived from human brain.
Methods. Fibroblast-like cells (BT cells) were readily cultivated from various types of human brain tumors. A mutant of HIV (HIV[GUN-1_V]) highly infectious not only to $T4^+$ T cells, but to BT cells was obtained by infection of BT cells with HIV[GUN-1_{WT}], which is infectious to $T4^+$ T cells, but almost not to BT cells. Genomes of HIV[GUN-1_{WT}] and HIV[GUN-1_V] were cloned from DNA of HIV[GUN-1_{WT}]-infected MOLT-4 and DNA of HIV[GUN-1_V]-infected BT cell, respectively. Various recombinant genomes were transfected to MT-4, and recombinant viruses were obtained.
Results. Infectivity of recombinant viruses to BT cells were tested. Viruses containing a 2.3 kbp PstI (Ps-b) fragment derived from HIV[GUN-1_V] clone were infectious to BT cells, whereas viruses containing Ps-b fragment from HIV[GUN-1_{WT}] failed to express HIV-antigens in BT cells. The Ps-b fragment encodes parts of env, rev and tat genes. In preliminary comparison of the sequences of the Ps-b fragments from the two viruses, we detected three nucleotide exchanges.
Conclusion. Difference in infectivities of HIV[GUN-1_{WT}] and HIV[GUN-1_V] to BT cells was coded for by the Ps-b fragment. Some of the three nucleotide exchanges might determine the host-range difference.

Th.C.P.135 INFECTION OF MESENCHYMAL CELLS WITH HIV-1 IN VITRO

Mellert, W.*, Kleinschmidt, A.**, Festl, H*, Schmidt, J*, Willer, A.*, Erfle, Volker*
*GSF-Abteilung für Molekulare Zellpathologie, D-8042 Neuherberg, **Medizinische Poliklinik der Universität München, D-8000 München, West-Germany.

Objective. Infection of mesenchymal cells of different origin (lung, skin, bone) with HIV-1 in vitro.
Methods. Infection of primary cell cultures and permanent cell lines with HIV-1 in vitro. Demonstration of virus infection and production by indirect immunoperoxidase staining (IP), in situ hybridization, reverse transcriptase activity (RT), electron microscopy and virus rescue.
Results. Different human cells of mesenchymal origin (primary skin fibroblasts, fetal lung cells, osteogenic cells) can be infected with HIV-1 in vitro. Especially in lung-derived cells, the infection was more pronounced, could be inhibited by anti-CD4 monoclonal antibodies and resulted in a persistent and productive infection similar to that of T-cells (RT activity, amount of infectious particles).
Conclusion. The productive and peristent infection of mesenchymal cells with HIV-1 indicates another potential virus reservoir in vivo which may contribute to local pathogenesis as for example in the lung (pneumonitis).

Th.C.P.136 SYNTHETIC SELECTIVE INHIBITORS OF HIV PROTEASE

Michejda, Christopher J., Blumenstein, J.J., Copeland, T.D., Oroszlan, S.
BRI-Basic Research Program, NCI-Frederick Cancer Research Facility, Frederick, MD, U.S.A.

Retroviral protease, the enzyme which processes viral precursor polyproteins, is essential for virus replication and thus is an attractive target for chemotherapeutic treatment of retrovirus infections. We have designed and synthesized a structurally simple and versatile class of compounds, 2,3-epoxy alcohols, acids, and derivatives, and found several of them to be selective inhibitors of the HIV protease. The effect of these compounds on chemically synthesized HIV protease was conveniently studied by monitoring the cleavage of an authentic single peptide bond in a synthetic nonapeptide corresponding to a natural cleavage site in HIV-1 *gag* precursor polyprotein. The relative inhibitory effects of these compounds have afforded an insight to the structural characteristics which impart activity. Several compounds which inhibited the HIV protease showed negligible inhibitory effect on renin, a related nonviral aspartyl proteinase. Preliminary studies indicate that some of these synthetic compounds inhibit viral infectivity without substantial cytotoxicity. These compounds represent an entirely novel class of agents against HIV infection.

(Research sponsored by the National Cancer Institute, DHHS, under contract NO. N01-CO-74101 with Bionetics Research, Inc.)

Th.C.P.137 COMPARISON BETWEEN IMMUNOCYTOFLUOROGRAPHIC ANALYSIS (ICF) AND IN SITU HYBRIDIZATION (ISH) IN DETECTION OF HIV INFECTION OF MONOCYTE-MACROPHAGES (Mφ).

Crowe, Suzanne: Elbeik, T. McManus, N. Lekas, P. Mills, J. McGrath, M.
San Francisco General Hospital/University of California, San Francisco, California, USA.

Objective: To compare the techniques of ICF and ISH in assessment of proportion of mφ which contain HIV antigen and HIV RNA respectively.
Methods: Mφ were isolated from (1) peripheral blood (PB) of HIV sero-negative donors (n=14) infected in vitro with HIV-DV at multiplicity of one; (2) PB of HIV-infected individuals (n=6). Mφ were stained with Mab directed against HIV p24 (provided by J. Carlson, U.C. Davis) and the proportion of cells expressing HIV was quantitated using an Ortho IIS cytofluorograph. Parallel samples of mφ were spotted onto slides, fixed and ISH was performed with ^{35}S-labelled full-length HIV-SF_2 gene probe (provided by Chiron, CA). Slides were coded and examined by a blinded observer.
Results: In the 20 samples examined, the proportion of mφ containing HIV antigen varied from 0-70% and the proportion of cells containing RNA varied from 0.001 - 88%. Linear regression analysis showed a strong correlation between the two methods (r=0.77). The calculated relationship between ICF and ISH is: % mφ HIV positive (ISH) = 0.8 [% mφ p24 positive (ICF)]- 3.75.
Conclusion: ICF and ISH correlate well in determining the proportion of mφ within a population which contain HIV p24 antigen or HIV RNA respectively.

Th.C.P.138 QUANTITATION OF HIV-1 IN PLASMA AND PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) OF SEROPOSITIVE PERSONS.

Ho, David D.; Alam, M.; Moudgil, T.; Lin, S. UCLA School of Medicine and Cedars-Sinai Medical Center, Los Angeles, CA, U.S.A.

Objective: To quantify the titer of infectious HIV-1 in plasma and PBMC.
Methods: Plasma (2, 10, 40, 200, 1000 ul) and PBMC ($2x10^2$ to $2x10^6$) were cultured with $2x10^6$ PBMC from normal donors, and HIV-1 replication was monitored by supernatant p24 expression twice weekly for up to 28 days. Infectious titers for plasma and PBMC were expressed as tissue culture infective doses (TCID) per ml and TCID per 10^6 cells, respectively.
Results:

		T4 #	Serum p24 (pg/ml)	plasma HIV-1 titer (TCID/ml)		PBMC HIV-1 titer (TCID/10^6 cells)	
	N	mean	mean	range	mean	range	mean
Healthy	5	431	7	5-100	24	5-50	23
ARC	8	140	434	25-500	196	50-5000	2675
AIDS	19	90	812	1-500	187	5-5000	1433

Conclusions: (1) Infectious HIV-1 was detected in the plasma of every seropositive person, suggesting that HIV-1 infection is active and not latent. (2) Symptomatic individuals have significantly more virus than asymptomatic subjects. (3) In 1 ml of blood, asymptomatic persons have approximately 15 TCID of HIV-1 in plasma and 25 TCID of HIV-1 in mononuclear cells, while ARC and AIDS patients have 140 TCID in plasma and 1000 TCID in cells. In fact, many symptomatic patients harbor HIV-1 in 1 in 200 PBMC, which is a virus load much greater than previous reports suggesting that only 1 in 10^5 or 10^6 cells carry virus. (4) This quantitative culture has been successfully applied in patients receiving azidothymidine to demonstrate the in vivo antiviral effect.

Th.C.P.139 THE BINDING OF HBsAg TO HUMAN T4 LYMPHOCYTES INDICATES THE POSSIBILITY OF THE ANTIGEN TO FUNCTION AS OLIGOPEPTIDE ANTAGONIST TO HIV PRIMARY INFECTION OF T4 LYMPHOCYTES.

Lakew Gebreselassie

National Research Institute of Health. P.O.Box 1242. Addis Ababa,Ethiopia

Objective. To evaluate if HBsAg can bind on CD4 receptor of human T4 Tymphocytes and to identify if it can function as oligopeptide antagonist to HIV primary infection of T4 lymphocytes.

Methods. HBsAg positive sera samples, partially purified HBsAg and highly purified HBsAg were assayed for HBsAg reactivity when tested with and without equal volumes of human T4 lymphocytes ($2x10^6$ cells) using Organon diagnostic kit for the detection of HBsAg.

Result. HBsAg reactivity in the samples gave higher OD reading when tested with the T4 lymphocytes than the same samples tested without the T4 lymphocytes.

Conclusion. HBsAg can bind on human T4 lymphocytes obviously on the CD4 receptor hence may function as oligopeptide antagonist to HIV primary infection of T4 lymphocytes. The application of oligopeptides of HBsAg in preventing HIV primary infection of T4 lymphocytes should be investigated in the future.

Th.C.P.140 ANALYSIS OF A FUNCTIONAL HIV-2 REV GENE

Sylvie Paulous, M. Emerman, and A. Cordonnier.
Unité d' oncologie virale, Institut Pasteur, Paris, France

Objective: HIV-1 Rev is required for HIV-1 envelope protein expression. We have begun a functional and structural comparison of the rev gene of HIV-2 with that of HIV-1 in order to better understand their mechanism of action.
Results and Methods: We constructed a cDNA library from HIV-2 infected cells and cloned a cDNA encoded the rev gene. The sequence of the rev cDNA shows that the rev gene of HIV-2 is encoded on a message with four exons. The first, from R to the major splice donor, and the second, a 72 bp exon in the pol gene, are non-coding. The first coding exon begins between the ATG of the tat gene and the ATG of the rev gene and ends after the ATG of the env gene. The second coding exon begins near the end of the env gene. The HIV-2 rev gene product is predicted to share 44% amino acid identity with that of HIV-1. To show that the HIV-2 rev cDNA was functional, co-transfections were done with another plasmid that encodes the envelope gene of HIV-2. We found that expression of the envelope protein of HIV-2 from a plasmid vector was dependent on co-transfection of the HIV-2 rev cDNA.
Conclusion: We have cloned a functional cDNA encoding the HIV-2 rev gene. Comparision of the specificity of the HIV-2 rev product with that of HIV-1 will be usefull in defining the target site of the HIV rev products.

Th.C.P.141 HUMAN MONOCLONAL ANTIBODY AGAINST HIV

Sagawa, Kimitaka: Sakata, K.; Katagiri, K.; Kubo, K.; Natori, H. and Yokoyama, M.M.
Kurume University School of Medicine, Kurume, Fukuoka, Japan

Objective. Attempts were made to produce monoclonal antibodies of human origin against HIV which have neutralizing antibody activity.
Methods. Mononuclear cells from peripheral bloou of the patients with hemophiliacs showing sero-positive to HIV and the healthy sero-negative donors were cultivated with inactivated HIV and CD28 antibody as an in vitro immunization for 4 days. On day 4, EBV was infected to the culture. After 2 to 3 weeks of cultivation the growth of EBV transformed B cell clusters was observed. Culture supernatant of propagated B cells through cloning procedure was tested for their antibody activity to HIV by using ELISA method, immunofluorescence method, and Western blot procedure.
Result. Series of experiments were performed on the mononuclear cells originated from 2 hemophilia B patients, 1 hemophilia A patient, and 2 healthy donors. Numbers of B cell clones were obatained from a hemophilia B patient in ARC stage, whereas no continuous propagation of B cells were observed on the cells from other donors. Some culture supernatants of the propagated B cell clones showed antibody activity to HIV by ELISA method. However, those positive reactivities have not been reproducible by immunofluorescence or Western blot procedure.
Conclusion. A procedure to produce human monoclonal antibody against HIV by EBV transformed B cell method has been partially established. Cloning procedure and screening procedure have to be improved to obtain B cell clones consistentely produce human monoclonal antibody to HIV.

Th.C.P.142 CHARACTERIZATION OF MONOCLONAL ANTIBODIES REACTIVE WITH DIFFERENT PROTEINS OF HIV1 - NDK STRAIN.

DEVAUX C., ROBERT V., TATSUMI M. and CHERMANN J.C.

Unité de Recherches INSERM sur les Rétrovirus et Maladies Associées (U.322) - Campus de Luminy - BP 33 - 13273 MARSEILLE Cédex 9 - FRANCE.

We attempt to generate monoclonal antibodies (mab) specific for the highly cytopathic strain HIV1-NDK. Until now, 6 mabs have been obtained : 3 mabs have been shown to react with epitopes of p 24 (mabs : BL 4.72.1 and BL 4.11.14) or gp120 (mab : BL16.76.1) shared among several HIV isolates. The 3 other mabs 2 of which react with epitopes of p17 (mabs : BL16.26.5 and BL16.45.1) and 1 with an epitope of p68 (mab : BL4.25.5) apparently bound specifically HIV1-NDK proteins. Further characterization is in progress to evaluate the biological effects of these reagents on HIV infection.

Th.C.P.143 DECREASING PRODUCTION OF IgG, IgM, AND IgA ANTIBODIES AGAINST PNEUMOCYSTIS CARINII ANTIGENS IN AIDS PATIENTS MESURED BY ELISA AND WESTERN BLOT.

PEDER BO NIELSEN*,ANNE GRETE POULSEN**,CLAUS KOCH**,BO HOFMANN*** AND MADELEINE MOJON****
*Bispebjerg Hospital,**Statens Seruminstitut and ***State University Hospital, Copenhagen, Denmark,****University Claude Bernard,Lyon, France.

Objective. The study assesses IgG, IgM, and IgA production against major Pneumocystis carinii (PC) antigens during the development of AIDS.
Methods. Eight homosexual AIDS patients were included in the study. Six patients suffered from PC Pneumonitis during the period and two patients had Kaposi's sarcoma. Between 2 and 21 sera per patient were examined for specific antibodies. Twenty-nine healthy volunteers served as controls. The antibodies were mesured by ELISA and Western blot using soluble PC-antigens.
Results. All patients, except one, had decreasing antibody level in all immunglobulin classes. The level of IgG and IgM were in all patients below the level of the normal subjects. However, the IgA level was during the whole period above the level of the normal subjects. Western blot reveal changes related to the major antigenic components with molecular weights of 66.000 and 55.000 Dalton. IgG from normal controls did not react in the 55 kDa region. In AIDS patients the reaction between the immunoglobulins and the antigenic components disappeared in the following order: IgG/66, IgA/55, IgM/55 and finally IgM/66 or IgA/66.
Conclusion. The humoral immunity against PC may serve as a marker for the degree of immunodeficiency in AIDS patients.

Th.C.P.144 B-CELL SYSTEM ACTIVATION AND HIV-1 INFECTION

Amadori,Alberto*; Zamarchi,R.*; Veronese,ML.*, Francavilla,E.** Barelli,A.***; Borri,A*** and Chieco-Bianchi L.*.
*Institute of Oncology, University of Padova; Dept. of Infectious Diseases,ULSS 21,Padova**; ULSS 36, Mestre*** - ITALY.

Objective. To better define B-cell activation during HIV-1 infection.
Methods. Limiting dilution assay of B-cell precursors spontaneously secreting HIV-1-specific and total Ig; absorption of culture supernatants with solid-phase HIV-1; effect of T-cell and monocyte removal, and interleukin addition, on in vitro spontaneous Ig synthesis.
Results. In vitro spontaneous Ig synthesis did not depend on T-cell presence, while monocyte removal caused a striking fall in spontaneous Ig production. IL-6 presence in culture was essential; antisera against IL-6 strongly reduced spontaneous Ig synthesis, which was partly restored by rIL-6 addition to monocyte-depleted populations. The frequency of B-cell precursors spontaneously producing HIV-1-specific Ab was about 1/3-1/4 of that of spontaneously activated, Ig-secreting precursors. Moreover, after absorption with solid-phase HIV-1, about 30% of total Ig was removed from unstimulated culture supernatants.
Conclusions. HIV-1-specific B-cell activation is a major constituent of the overall B-cell activation in PBL from seropositive subjects. This phenomenon can contribute to the virus-induced immune damage, and partly explain the increased frequency of AIDS-associated B-cell malignancies.

Th.C.P.145 FINE STRUCTURE OF INSIDE THE VIRAL ENVELOPE OF THE HIV-1

Ichiro Takahashi*, A-M Ladhoff**, M Takama* and D Scholz***
*Central Laboratory for Electron Microscopy, Teikyo University School of Medicine. Tokyo, Japan. **Institut für Pathologishe Anatomie, and ***Institut für Virologie, Humboldt Universität zu Berlin.
FEDERAL REPUBLIC OF GERMANY

Objective. We presented an envelope surface model of HIV-1 using a computer image processer with negatively stained electron micrographes, namely, envelope structure of HIV-1 particle is constructed of T=7 laevo symmetry icosahedron and 72 knobs(gp120/gp41) are stuck into the envelope on the pentamer/hexamer clustering positions(4th. Int. Conf. AIDS: abstract No. 1042, and J. AIDS in press). Our results support the studies presented by Gelderblom et al.. In this study we will indicate some structures under the viral envelope.
Methods. HIV-1 particles were obtained from the HIV-producing H9-clones of the HT-lymphocyte line. The unfixed particles were negatively stained with 2% phosphotungstic acid(pH 6.6) and then dried in air to obtain well preserved structures.
Results. From the electron microscopic observations following features will be suggested.

1) The core shell has a polyhedral structure.
2) The space between viral envelope and core shell is filled with fibrous structures.

We also show a three dimensional model.

Th.C.P.146 SOME OBSERVATIONS ON THE LATENT HIV INFECTION PERIOD

Pezzella M.+; Mirolo,M.++; Miceli,M.++; Rosci M.A.+++; Vonesch,N.+ and Mannella E.++
+ Institute Infectious Diseases, Policlinico Umberto I, University of Rome
++National Center for Blood Transfusion C.R.I.; Ospedale L. Spallanzani , Italy

Objective. To evaluate the latent HIV infection period, from January 1988 to December 1988 six seronegative regular sexual partners of HIV infected subjects has been studied.
Methods. The seronegative diagnosis has been based on the demonstration of the absence of specific serum antigen and antibodies to the viral proteins by ELISA and Western Blot tests. The HIV latent infection has been evaluated by "in situ" hybridization on peripheral blood mononuclear cells (PBMCs) using an SP 64 plasmid containing the SstI-SstI 9 kb viral insert lambda BH 10 recombinant clone tagged with a sulfone group and visualized by double immunohistochemical antibody reaction. The controls were performed using HIV infected and non infected H 9 culture cell lines and PBMCs from healthy blood donors.
Results. The HIV genome was evidenziated, at first control, in the cytoplasm of mononuclear cells of all the seronegative subjects as a granular staining (alkaline phosphatase). Five subjects showed a transient positivity for anti-p 24 and three for specific HIV antigen. One subject seroconverted three months after first control.
Conclusions. The "in situ" hybridization is a useful technique to recognize HIV infection at very early stage.

Th.C.P.147 HIV-1 DOES NOT REPLICATE IN HUMAN VAGINAL EPITHELIAL CELLS

Sunstrum, James; Meriwether,C; and Sobel, J.
Wayne State University, Detroit, MI, USA 48201; Veterans Administration Med. Ctr., Allen Park, MI, USA 48101

Objective. To determine the ability of HIV-1 to replicate in human vaginal epithelial cells, a potential cellular target in heterosexual transmission.
Methods. Vaginal epithelial tissue explants obtained from HIV-seronegative women undergoing hysterectomies were seeded in tissue culture wells for 12 days. Cell-free supernatant from H9/HTLV-IIIB cells was added and adsorbed X 18 hrs. Explants were washed three times with saline, refed, and examined for morphological changes and supernatant HIV p24 antigen (Abbott) at times 0, 3, 6, 10, and 18 days following viral inoculation.
Results. No morphological changes were detected for tissue explants inoculated with HIV when compared to uninoculated wells. Spreading monolayers consisting of epithelial and/or fibroblasts were observed in all wells, and increased in size regularly. Supernatant p24 antigen levels were negative in all wells at the time points examined.
Conclusion. Human vaginal epithelial cells cannot support HIV replication when examined for up to 18 days following inoculation with a lymphoblastoid-adapted strain of virus. Experiments are in progress to determine whether a macrophage-adapted strain of HIV can infect vaginal tissue explants.

Th.C.P.148 EXCRETION OF HUMAN IMMUNODEFICIENCY VIRUS IN BODY FLUIDS

*Cordery, Mark, *Barrett, Y, *O'Shea, S, *Banatvala, JE, **Bradbeer C.
*Department of Virology and **Genito-Urinary Medicine, St Thomas' Hospital, London, UK; Abbott Diagnostic Division.

OBJECTIVE: To evaluate techniques to assess HIV excretion patterns and specific antibody responses in body fluids.
METHODS: Peripheral blood, semen, saliva and female genital secretions from asymptomatic and symptomatic patients are being examined for infectious virus, viral antigens (EIA and flow cytometry), viral nucleic acid (PCR to follow) and antibodies (EIA and Western Blot).
RESULTS:

Sample	Infectious Virus	p24 Antigen	IgG	IgA
Blood	*24/31 (77%)	11/31 (35%)	31/31 (100%)	9/12 (75%)
Semen	3/12 (25%)	0/25	29/30 (96%)	11/13 (84%)
Saliva	0/12	0/18	23/25 (92%)	1/15 (6%)
Genital secretions	To follow	0/5	4/5 (80%)	To follow

* Nos positive/nos tested

Positive cultures occurred within 3-7 days among symptomatic and 7-28 days among asymptomatic patients. We have shown that flow cytometry provides an efficient method for analysis of cell populations in blood and female genital secretions; we have not yet detected expression of HIV antigens.
CONCLUSIONS: Infectious virus and viral antigens were detected less frequently in semen and saliva which may reflect the fact that they contain specific antibodies. These fluids probably represent a low risk for transmission of virus. Detection of positive cultures earlier among symptomatic than among asymptomatic patients suggests higher virus load or strains that replicate more efficiently.

Th.C.P.149 MOLECULAR CHARACTERIZATION OF A DEFECTIVE HUMAN IMMUNODEFICIENCY VIRUS

M. Inoue*, J. A. Hoxie** and E.P. Reddy*
*The Wistar Institute, Philadelphia, PA, **Hospital of the University of Pennsylvania, Philadelphia, PA, U.S.A.

Prolonged culturing of H9IIIB cell line, chronically infected with HIV-1, resulted in the emergence of a variant cell line that was found to be defective for virus production. This cell line (M-IIIB) was tested for the production of p24 antigen by ELISA and was found to be negative. Similar negative results were obtained when the cells were analyzed by FACS using monoclonal antibodies to p24. However, these cells were found to produce large quantities of HIV envelope gene product and were found to induce massive syncytia when cocultured with SUP-T1 cell line which is a CD4+ T-lymphocytic leukemia cell line. Immunoprecipitation analysis of the labelled cell lysates revealed the synthesis of envelope gene products (gp160, gp120). As predicted, there was no synthesis of p24 antigen as well as gag precursor protein, p55. The Southern blotting analysis of the M-IIIB cell DNA revealed the presence of a single proviral genome in cellular DNA. Following digestion with XbaI, which cleaves outside the proviral genome, the DNA was fractionated and cloned into a λ phage vector. A molecule analysis of the proviral genome aimed at understanding the nature of defect will be presented.

Th.C.P.150 HIV: EARLY VIRUS-CELL INTERACTIONS

Grewe, Carola; Beck, A.; Gelderblom H.R.
Robert Koch-Institute, Berlin, FEDERAL REPUBLIC OF GERMANY

Objective. HIV infects CD4+ cells, mainly lymphocytes and monocytes. Two entry mechanisms have been observed in different reports: 1. direct fusion of the viral envelope with the cell membrane, 2. receptor-mediated endocytosis via clathrin coated pits and vesicles.
Method. Uninfected cells were incubated with purified virus and studied by EM at different time intervals and temperatures with regard to adsorption, fusion mechanisms and penetration of the core. Results. Since fusion was seen not only within cytoplasmic vesicles but also at the cell surface of both lymphocytes and macrophages, virus entry seems to be pH independent. The two layers of the viral envelope and the lipid bilayer of the cellular membranes usually fuse seamlessly within 1-3 min, but occasionally membrane ruptures may also occur, leading to rapid cytopathic effects, i.e. vacuolization and cytolysis. In the course of fusion at the cell surface, the viral envelope glycoprotein gp120 is integrated into the lipid bilayer of the cell membrane, where it can be visualized by immuno electron microscopy. Free gp120, shed by the mature virion already before attachment to the cell, may also bind to the cell surface and is most frequently found within clathrin coated pits. Formation of syncytia by cells studded with viral proteins was observed as early as after 1h of incubation with virus. SBL6669(HIV-2) Syncytia reach a larger size than HTLVIII-B (HIV-1) Syncytia.
Conclusion. The rapid entry of HIV into its host cell as well as early cytopathic effects should be considered in attempts to block virus entry or replication.

Inhibition of retrovirus-induced diseases by two naturally occurring polycyclic aromatic diones hypericin and pseudohypericin

Gad Lavie and Daniel Meruelo,
Dept. of Pathology, New York University School of Medicine, New York, N.Y. U.S.A.

Two aromatic polycyclic dione compounds hypericin (HY) and pseudohypericin (PS) have been found to markedly inhibit the onset and progression of retrovirus induced disease. The compounds were originally derived from plants of the hypericum family (St. Johnswort). Their intravenous administration to mice infected with Friend virus at the time of virus inoculation can completely prevent the onset of leukemia and death. Intraperitoneal administrations shortly after virus inoculation significantly reduces splenomegaly associated with this disease as measured 10 days post virus inoculation, but does not completely prevent disease inductions. Another mouse model in which the antiviral efficacy of the compounds has been monitored is the murine immunodeficiency virus model (MAIDS), induced by the LP-BM5 virus. In our hands viremia in mice infected with the virus begins approximately 14 days post virus inoculation. Administrations of HY or PS intraperitoneally once every two weeks, beginning on day 14 after virus inoculation markedly reduced viremia to almost background levels throughout a 90 day follow up. Splenomegaly was also reduced by 66.2% after treatment with HY and by 49% after treatment with PS. These data coupled with the demonstrated in vitro activity of these compounds against retroviruses including human immunodeficiency virus, HIV, suggest that these compounds may have potential value as therapeutics for the treatment of diseases such as AIDS.

C.502

TRANSMISSION OF SIV_{mac} TO BABOONS

Cranage, Martin*; Baskerville, A.*; Stott, E.**; Kitchin, P.**; et al. *P.H.L.S. C.A.M.R., Salisbury SP4 0JG, U.K. **Collaborating Centre on AIDS, N.I.B.S.C., Potters Barr EN6 3QG, U.K.

Objective. To study the transmissibility and course of infection of freshly isolated SIV_{mac} in baboons and rhesus macaques.
Methods. Virus was isolated from a rhesus macaque 57 days after intravenous inoculation with SIV_{mac251} (from Dr Desrosiers) by co-cultivation of monkey PBL with human cord blood lymphocytes. This isolate was authenticated as SIV_{mac} by serology, electron microscopy and sequence analysis of PCR-amplified-gag. Blood from the infected animal, CEL and C8166 adapted virus was inoculated into 3 baboons and 3 rhesus macaques. These animals were monitored for seroconversion, virus isolation and disease status.
Results.

Animal No.	Inoculum	Virus Isolation			West. Blot		ELISA
		Day 38	Day 96	Day 129	p28/14	gp 32-37	gp 125
Rh 61H	Blood	+	+	+	+	+	+
Bab 36617		-	+	-	+	+	+
Rh 19H	Virus	+	+	+	-	+	+
Bab 36638	(CEL)	+	+	+	+	+	+
Rh 14H	Virus	+	+	+	+	+	+
Bab 36626	(C8166)	±	-	-	+	+	+

At 7 months no animals have disease.
Conclusion. Baboons are susceptible to infection with SIV_{mac}.

C.504

DIFFERING EFFECTS OF HELPER T LYMPHOCYTE DEPLETION ON MURINE INFECTION WITH HERPES SIMPLEX (HSV) AND CYTOMEGALOVIRUS (MCMV)

Mills, John*; Erlich, K*; Wofsy, D*; Shanley, J**; *Univ. of Calif., San Francisco & **Univ. of Connecticut, Newington, U.S.A.

Objective: To determine effect of helper-inducer T lymphocyte depletion on the pathogenesis of HSV and MCMV infection of mice.
Methods: Injection of rat monoclonal antibody GK1.5 into mice causes >95% depletion of L3T4 lymphocytes (the murine homologue of CD4 lymphocytes).
Results: In this model, resistance to acute HSV encephalitis is little impaired (virus LD_{50} decreased from 10 to 10 pfu/mouse; brain virus titers unchanged), even though depleted animals fail to generate humoral or cellular immunity to HSV. The L3T4-depleted mice have intact natural killer cell activity, which may contribute to host defenses in the absence of L3T4 lymphocytes. In marked contrast to HSV, acute CMV infection was profoundly altered by L3T4 lymphocyte depletion. Virus replication in depleted animals was prolonged by 3-4 weeks and increased (e.g. peak salivary gland titers increased from 10^{8} to 10^{10} pfu/gm). As expected, depleted animals made <5% of the anti-MCMV antibody of controls. Despite humoral immunodeficiency and markedly augmented virus replication, L3T4 depleted animals were more resistant to infection than normals (LD_{50} increased from $10^{3.6}$ to $10^{4.5}$ pfu/mouse).
Conclusion: Depletion of murine helper-inducer lymphocytes consistently results in augmented replication of herpesviruses, but the effect on host defenses is unpredictable: depletion increases mortality following HSV infection but decreases mortality following CMV infection.

IDENTIFICATION and CHARACTERIZATION of RABBIT CD4 USING ANTISERA PREPARED AGAINST HUMAN CD4

Mark R Gordon* and Thomas J Kindt
Laboratory of Immunogenetics, NIAID, NIH, Bethesda, MD 20892; U.S.A.

Objective: To prepare and characterize antisera which bind rabbit CD4 and to identify T-cell subpopulations in normal and HIV-1 infected rabbits.
Methods: Goats, sheep and chickens were each immunized subcutaneously with 80 ug of recombinant soluble human CD4 (gift of D. Capon, Genentech Inc.) in 0.1 ml complete Freunds adjuvant. Subsequently, the animals were given weekly booster immunizations of 80 ug each in incomplete Freunds commencing on day 21 and continuing for 4 weeks. On the fourth week, the goats and sheep were boosted as usual with CD4, and sera were collected four days later; the chickens were boosted with 5 million rabbit thymocytes, and sera were collected four days later. All sera were tested by immunofluorescence (microscopy and flow cytometry) and by immunoprecipitation to detect the presence of antibodies to rabbit and human CD4.
Results: The goat and chicken antisera bound a subpopulation of T-cells from rabbit spleen, lymph node, thymus, and appendix. Cell staining of rabbit PBL were inconsistent and work is continuing. The sheep antisera were negative on rabbit cells. The goat antisera also bound A3.01 (human CD4+ T-cell line) but not A2.01 (human CD4- T-cell line) cells. Immunoprecipitation of human CD4 has been accomplished with goat antisera but not with chicken or sheep antisera. Preliminary experiments show that soluble human CD4 reduces the binding of goat and chicken antisera to rabbit cells. Additional experiments also indicate that A3.01 absorption of goat antisera removes its ability to bind rabbit CD4. Experiments in progress include: immunoprecipitation of rabbit T-cell lysates, absorption of antisera with immobilized CD4, and double staining in the context of known rabbit antibodies.
Conclusion: Cross-reactive epitopes exist between human and rabbit CD4 suggesting that binding of CD4 to HIV is a possible mechanism for HIV infection of rabbits.
*Recipient of an NRC fellowship.

C.510

DEVELOPMENT OF A NEUTRALIZING ANTIBODY ASSAY FOR THE SIMIAN IMMUNODEFICIENCY VIRUS MODEL

Maxfield, Lori; Jennings,M.; Holmes,E.; and Carlson,J.
Dept. of Medical Pathology, University of California, Davis, U.S.A.

Objective. To develop a neutralization antibody assay (Nt assay) that will be used to monitor SIV infected monkeys. Methods. Four cell lines (Hut 78, MT-2, MT-4 and CemXI74) were infected with a standard stock of SIV supernatant and monitored for infection by Reverse Trascriptase assay (RTA), P24 antigen assay (Dupont), and by cell viability using MTT. The $TCID_{50}$ value calculated using each system was compared. Results. The most reproducible $TCID_{50}$ was in the Hut 78 cell line using the antigen assay to determine the endpoint. The RTA gave similar results as the Dupont antigen assay, but it was more difficult to determine the negative cut-off. When MTT was used, the cell line MT-4 provided the highest $TCID_{50}$, however, these results were not consistent. A Nt assay using Hut 78 cells as the target for SIV with an antigen assay to determine the titer, was used to test the sera from SIV infected Rhesus monkeys. By this assay, sera from preinoculated monkeys were consistently negative for Nt antibodies and sera from 5 monkeys that had been infected for at least 2 months gave reproducible neutralizing titers that ranged between 1:64 and 1:512. Conclusion. An assay to test for Nt antibody titers in rhesus nonkeys infected by SIV was developed and found to be reproducible.

C.511

ROLE OF ETHANOL-INDUCED IMMUNOSUPPRESSION ON DISEASE AND TUMOR RESISTANCE OF RETROVIRALLY INFECTED MICE.

Darban, Hamid R., Huang, D.S., and Watson, R.R., University of Arizona, Tucson, Arizona, USA 85724.

Objective. To develop a murine model of AIDS for study of immunomodulatory cofactors as reviewed in Life Sci. 44:i, 1989. To determine the effects of a murine retrovirus causing immunosuppression, alone and with dietary ethanol, on cellular immune functions. Then to assess the effects of immunosuppression on infectious disease and tumor resistance.
Methods. C57BL6 female mice were infected with a murine retrovirus, LP-BM5, as described in Life Sci. 43:v, 1988. Mice were fed a liquid diet with 5% ethanol 5 days which produced withdrawal upon cessation. Controls were fed the diet with sucrose replacing ethanol. Then lab chow followed for 10 days with the cycle repeated over the course of the experiment. The mice were challenged with Streptococcus or syngeneic tumor PYB6.
Results. Effects of dietary ethanol in frequency of lymphocytes identified by surface markers 8 weeks post-LPBM5 murine leukemia virus infection.

Treatment	Control		Ethanol	
Virus Infection	-	+	-	+
T-helper	33.5 ± 4.9	24.3 ± 1.1	38.0 ± 2.5	41.0 ± 2.6
T-suppressor/cytotoxic	20.5 ± 0.7	11.3 ± 0.5	20.6 ± 1.1	19.0 ± 2.6
Activated Macrophages	23.0 ± 18.3	5.6 ± 2.0	17.0 ± 2.6	3.3 ± 1.1

Resistance to challenge by PYB6 tumor, S. pneumonia or both was assessed.
Conclusion. Ethanol suppresses numbers of T-cells and macrophages. It further suppresses immune functions in retrovirally infected mice beyond that caused by the virus. The murine AIDS model shows promise for investigating immunomodulatory effects of cofactors like alcohol us during retroviral infection on disease and tumor resistance. Supported by NIH Grant AA08037.

C.512

DEVELOPMENT OF MURINE RETROVIRUS MODEL USING F_1 HYBRID MICE FOR EVALUATION OF THERAPEUTIC SUBSTANCES

Morrey, John D.; Warren, R. P.; Burger, R. A.; Okleberry, K. M.; Sidwell, R. W. AIDS Research Program, Department of Animal, Dairy and Veterinary Sciences, Utah State University, Logan, Utah U.S.A.

Objective: To develop a predictive murine model for AIDS using an F_1 hybrid mouse strain capable of eliciting viral specific neutralizing antibodies that reduce retrovirus titers near limits of detection, but which still die of the disease, and to use this model for evaluating potential anti-AIDS therapies.
Methods: The utility of this mouse model was demonstrated by chronically treating female (B10.A X A/WySn)F_1 mice with zidovudine (AZT) 4 hrs. or 6 days after injection of Friend virus complex (FV). Per os (p.o.) and intraperitoneal (i.p.) treatment with an immunomodulator (bropirimine, ABPP) was also evaluated, with treatments started at 1 day pre-, 4 hr pre-, or 4 hr post-FV injection. Spleen weights, FV infectious centers in the spleen, cell-free virus in the spleen, plasma FV, FV-specific neutralizing antibody, cell enumeration by FACS analysis, and blastogenesis response were monitored
Results: AZT: When AZT was given i.p. or in the drinking water 4 hr after FV injection, the viral infection was prevented and immune parameters were not altered by the virus. When AZT was administered beginning 6 days after FV injection, viral titers were reduced but not eliminated. ABPP: When viral parameters were monitored 14 days post-FV injection, p.o. or i.p. treatment of ABPP did not affect viral parameters. Spleen weights were increased in the ABPP treated mice. When monitored at day 4 post FV injection, infectious centers in the spleen and spleen weights were increased in mice treated p.o. with ABPP.
Conclusions: Early treatment with AZT may prevent FV disease, but later treatment after virus exposure only reduces viral parameters. Enhancement of viral parameters by ABPP demonstrates that care must be used in application of immunomodulators. (Supported by NIH AIDS Program Contract NO1-AI-72662.)

C.513

A NEW SIMPLIFIED ASSAY FOR NEUTRALIZING ANTIBODIES TO HIV-1

Weislow,Owen*;Kiser,R.*; Fowler,A.**; Arthur,L.*; Nara,P.*** and Boyd,M.****.
*Program Resources, Inc., NCI-Frederick Cancer Research Facility, Frederick, MD, USA; **SRA Laboratories, Rockville, MD, USA; *** Division of Cancer Etiology, NCI, Frederick, MD, USA; **** Developmental Therapeutics Program, Division of Cancer Treatment, NCI, Frederick, MD, USA.

Objective. To develop a simple, large-scale assay for the safe and rapid quantitation of antibodies which block HIV-1 infectivity.
Methods. The reduction of a new tetrazolium salt, XTT, by viable T-lymphoblastoid cells to a soluble formazan was used to quantitate HIV cytopathic effects in a semi-automated 5-day microculture procedure for evaluation of neutralizing antibodies. Comparative methodologies included analysis by syncytium assay, quantitation of p24 synthesis, and anti-HIV-1 gp160/gp120 binding titers.
Results. The tetrazolium assay permitted screening large numbers of human and non-human primate sera including selected, AIDS patient sera and sera from iscom-vaccinated chimpanzees and rhesus monkeys for antibodies to HIV-1. Sera from goats immunized with HIV gp160/gp120 were also evaluated for specificity of reactivity permitting development of a competition neutralization assay.
Conclusion. The soluble formazan based tetrazolium assay can be employed for large-scale screening of sera from a variety of species for neutralizing antibodies to HIV. This new assay eliminates manipulations associated with other tetrazolium assays and is sensitive enough to permit evaluation of antibody binding specificities. Supported in part by NOI-CO74102

C.515

ANTISPERM ANTIBODIES AS A RISK FACTOR FOR SEXUALLY TRANSMITTED HIV INFECTION

Witkin, Steven S. and Jeremias, J.
Cornell University Medical College, New York, New York U.S.A.

Objective. To determine whether men with antisperm antibodies in their semen will be more likely than men who are not sensitized to sperm to transmit HIV to their sexual partners. Men with a history of STDs and homosexual men have a high incidence of antibodies to sperm.
Methods. Sperm from fresh ejaculates were tested for bound antibodies by the Immunobead assay. Seminal mononuclear cells were purified by Ficoll-Hypaque gradient centrification and CD4 and CD8 T lymphocytes quantitated by immunoperoxidase staining using monoclonal antibodies. Interferon gamma (IFN) in seminal fluid was measured by ElISA. The ability of sperm with or without bound antibodies to induce IFN production or immunosuppress allogeneic mononuclear cells was determined by co-culture.
Results. CD8 cells predominate over CD4 cells in semen from men with antibody-free sperm. In men with antibody-bound sperm there is a selective loss of CD8 cells so that CD4 cells now predominate. IFN is present in semen only from men with antibody-bound sperm. Antibody-bound sperm induces IFN from allogeneic lymphocytes while antibody-free sperm inhibits allogeneic lymphocyte proliferation.
Conclusion. CD8 cells normally predominate in semen and the male genital tract and sperm are immunosuppressive. This inhibits replication of HIV-infected mononuclear cells. In men with antibodies to sperm, however, CD4 cells predominate in semen and their sperm are IFN inducers. This promotes replication of HIV-infected cells in the male and enhances viral infectivity.

C.517

QUANTIFICATION OF HIV-BINDING TO CD4+ CELLS USING FLOW CYTOMETRY

[1]Thiele, Bernhard; [1]Kunze, R.O.F.; [2]Gebauer, F; [1]Ramirez, G.; [1]Gelderblom, H.; [1]Pauli, G.
[1]Abt. Virologie des Robert Koch-Instituts und AIDS-Zentrum, BGA-Berlin,
[2]Max Plank-Gesellschaft, AG Rheumatologie, Universität Erlangen-Nürnberg

The anti-CD4 antibody Leu 3a is able to inhibit HIV-virion binding to its receptor, the CD4 molecule. (Weiss et al., 1984). On the other hand, the viral protein gp120 can block Leu 3a antibody binding. Titration of fluorescein-conjugated Leu 3a in combination with Scatchard-Plot analysis of flow cytometric data gives a good estimate of the average number of CD4 molecules per cell and of the corresponding affinity constants. Such the optimum Leu 3a concentration with the highest sensitivity to interfering ligands can be used in further experiments. Human peripheral blood lymphocytes were incubated with supernatants of HIV-producing cell lines (Molt 4/8, H9), washed and fixed. The remaning binding capacity for Leu 3a was determined using a calibrated flow cytometer. The decreased fluorescence intensity compared to appropriate controls can be regarded as a measure of gp120 blocked CD4 and intact virions. Ultracentrifugation of HIV containing supernatants makes it possible to distinguish free gp120 from particle-associated glycoprotein and to estimate the content of virions with ability to bind to cells. In all experiments performed receptor occupation by HIV-virions or their glycoprotein did not exceed 50% of the CD4 molecules wich is in good agreement with theoretical considerations

C.514

ANTIBODY DEPENDENT CELL-MEDIATED CYTOTOXICITY (ADCC) IN RELATION TO CLINICAL PROGRESSION OF HIV-1 ASSOCIATED DISEASE IN HAEMOPHILIACS.

Sinclair, Anne L., Habeshaw, J., Muir, L., Steele, M.,* Ludlam, C.** and Dalgleish A.G.
MRC Clinical Research Centre, Harrow, UK, *MRC Clinical Cytogenetics Unit, Edinburgh, UK, **Scottish S.E. Regional Blood Transfusion, Edinburgh, UK.

Objective. Evaluation of the ability of serial serum samples from a cohort of HIV-1 positive haemophiliacs to mediate ADCC, with study of the relationship of ADCC to clinical state and disease progression.
Method. HIV-1 isolates in the CEM cell line were used as target cells and peripheral blood mononuclear cells from selected normal donors as effector cells*. Comparison of serial samples from 36 HIV-1 positive haemophiliacs infected with the same contaminated factor VIII is described. Titres of antibody mediating HIV-1 specific ADCC are compared with the evolution and clinical stage of HIV-1 associated disease.
Results. Preliminary results show that 7/7 ARC/PGL patients with non-progressive disease have higher ADCC than 2/2 patients progressing to AIDS. Full results of 30 patients will be presented.
Conclusion. Our preliminary studies as well as those from other groups suggest a protective function of sera that can mediate HIV-1 specific ADCC. If the trend is confirmed the findings will be of importance in design of HIV vaccines and therapeutic strategies.

C.516

MODULATION DE L'EXPRESSION DE CD4 PAR LE PMA ET INFECTION VIH IN VITRO

Sanhadji Kamel, Benard, I. et Touraine, J. L.
Faculté de Médecine A. Carrel, INSERM U80-CNRS URA 1177, Lyon, France

Objectif. La liaison de la glycoprotéine 120 (gp120) à la molécule CD4 constitue l'un des mécanismes principaux de l'infection de la cellule par le virus de l'immunodéficience humaine (VIH). La modulation de l'expression de CD4 in vitro, par le phorbol myristate acétate (PMA), permet d'étudier les conditions d'infectivité de la cellule par le VIH.
Méthodes. Des cellules de lignée lymphoïde MT4 sont prétraitées avec PMA (10^{-8}M) pendant 1,5 et 16h. Le phénotype CD4 de ces cellules est analysé en immunofluorescence avant l'infection par VIH in vitro. L'évaluation de l'infection virale est basée sur l'apparition d'un effet cytopathogène (ECP), l'expression intracytoplasmique de l'antigène viral p24 et d'une activité transcriptase inverse ou RT.
Résultats. Les cellules MT4 expriment, à plus de 80 %, la molécule CD4 et les conditions de leur infection in vitro par PMA ont été définies.Le traitement, des MT4 au PMA, pendant 1,5 et 16 h a permis une forte réduction de l'expression CD4 associée à une absence d'ECP et de p24 intracytoplasmique. L'activité RT était absente après 1h d'incubation au PMA mais par contre détectable à 5 et 16 H de prétraitement au phorbol.
Conclusion. Ces résultats confirment que l'infectivité in vitro par VIH est associée avec le degré d'expression de la molécule CD4.

C.518

SPONTANEOUS TNF-ALPHA PRODUCTION BY ALVEOLAR MACROPHAGES AND PERIPHERAL BLOOD MONOCYTES FROM PATIENTS WITH AIDS.

Krishnan, Vijaya; Mitchell,D.;and Pinching,A.J.
St. Mary's Hospital Medical school, London, U.K.

Objective: To assess spontaneous and LPS induced TNF-alpha production by monocytes/macrophages from AIDS patients.
Method: Bronchoalveolar lavage (BAL) cells and peripheral blood mononuclear cells (PBMC) were cultured for 24 hours, with and without LPS (1ug/ml), aftur which supernatants were collected and assayed for TNF by ELISA. Patient groups included:

Group 1 - HIV positive patients with PCP (AIDS).
Group 2 - HIV positive patients without PCP, but with bacterial infection (ARC or AIDS)
GROUP 3 - HIV negative patients with negative bronchoscopy for - carcinoma.

Result:		Group 1	Group 2	Group 3
BAL cells	Spontaneous	177.6 ± 53.1 (n=17)	25 (n=8)	26 ± 1 (n=15)
	LPS induced	231.5 ± 84.8	268.2 ± 36	298.6 ± 54.3
PBMC	Spontaneous	55.05 ± 18.7 (n=8)	25 (n=8)	25 (n=8)
	LPS induced	136.8 ± 33.8	135 ±47.3	133.2 ± 20.9

[Figures are mean values of TNF, expressed as units/ml/10^5 macrophages. Values lower than the limit of detection of the assay (25 units/ml) were assigned a value of 25]
Plasma and BAL fluids did not contain detectable TNF.
Conclusion: AIDS patients with Pneumocystis carinii pneumonia,but not those with bacterial infection, showed increased spontaneous TNF-alpha production.

C.519

INDUCTION OF MAJOR HISTOCOMPATIBILITY (MHC) CLASS II ANTIGEN ON CELLS OF THE DEVELOPING HUMAN FETAL PERIPHERAL NERVOUS SYSTEM BY GAMMA-INTERFERON

Boyer, Beth A. and Wigdahl, B.
Department of Microbiology and Immunology, The Pennsylvania State University College of Medicine, Hershey, PA 17033 USA

Objective. To examine the effect of gamma interferon (γ-IFN) on the level of MHC class II expression on cells isolated from the developing human fetal peripheral nervous system.
Methods. γ-IFN was used to study the induction of MHC class II antigen expression on the surface of cells obtained from dorsal root ganglia (DRG) derived from aborted human fetal specimens between 13 and 16 weeks gestation. The induction of class II antigen expression by γ-IFN was also examined on U373 glioma cells. Fluorescence-activated flow cytometric analysis was performed on both live and fixed cells utilizing a primary monoclonal antibody specific for the HLA-DR (MHC class II) region-associated bimolecular complex in conjunction with a fluorescein-conjugated goat anti-mouse secondary monoclonal antibody.
Results. We have demonstrated that between 15 and 25% of human DRG neural cells isolated from aborted human fetal specimens are HLA-DR antigen-positive. However, when human fetal DRG neural cells isolated from the same tissue were treated for 48 hr with γ-IFN (100 U/ml), the number of HLA-DR antigen-positive cells increased to between 41 and 71%. Kinetic analysis of MHC class II antigen expression in the U373 glioma cell line after treatment with γ-IFN (100 U/ml), demonstrated an increase in the number of HLA-DR antigen-positive cells, reaching a maximum of 86-98% antigen-positive cells within 48 hr after exposure, declining thereafter, but remaining above pretreatment levels 24 hr later.
Conclusion. γ-IFN enhances MHC class II expression on human fetal DRG neural cells. Future studies will examine the effects of HIV infection, HIV antigens, and factors secreted by HIV-infected cells on MHC class II expression in the developing human nervous system.

C.520

DECREASING ANTIBODY RESPONSES IN ASSOCIATION WITH AIDS

Hendry, R. Michael*; Katzenstein, D.*; McCutchan, J.A.**; Sawyer, L.A.*; Vujcic, L.K.*; Quinnan, G.V.*; et al. *LRR, BV, Center for Biologics Evaluation and Research, FDA, Bethesda, MD, U.S.A. and **UCSD AIDS Cohort Study, San Diego, CA., U.S.A.

Objective. To identify HIV specific immune responses associated with the development of AIDS in HIV seropositive homosexual men.
Methods. Sera were obtained semi-annually over 3 years from 20 asymptomatic HIV seropositive men in San Diego, 10 of whom developed AIDS and 10 remained stable. They were studied by quantitative Western Blot (WB) neutralising antibody (NA) and antibody-dependent-cell-mediated-cytotoxicity (ADCC) assays.
Results. Quantitative analysis of the IgG binding to individual proteins and glycoproteins of HIV on WB demonstrated no differences between the groups at the initial visit. After 2-3 years, there was a significant decrease in antibodies against p24, p31, gp41, and p55 in the group with AIDS compared to the stable subjects ($p < .03$, Mann-Whitney). NA decreased in 6/10 subjects with AIDS and 2/10 stable subjects. Reciprocal geometric mean titers (GMT) of NA were identical in the two groups at presentation (79), but 3 years later it was significantly lower in those with AIDS (30 vs 70 $p < .05$ Student's t test). ADCC was detected in sera at ≥1:1,000 in 17/20 subjects and there was no difference or change in ADCC titers between the groups over time.
Conclusions. Development of AIDS in initially asymptomatic HIV seropositive homosexual men was associated with a decline in HIV specific antibodies against core antigens and NA but not ADCC or envelope binding antibodies as detected by WB.

C.521

THE EFFECT OF HIV ON THE EXPRESSION OF HLA-DR AND CYTOCHROME-b OXIDASE mRNA IN MONONUCLEAR CELLS

Tobin, Ellis H. and Remold, H.
Harvard Medical School and Brigham and Women's Hospital, Boston, MA, USA.

Objective. To determine if HIV infection can alter the expression of two distinct mRNA markers of mononuclear cell activation: 1. HLA-DR--the major histocompatability antigen responsible for accessory cell function; and 2. Cytochrome b heavy chain (cyt-b)--a component of the oxidase system responsible for mononuclear cell respiratory burst activity.
Methods. The HTLV-III$_B$ strain was used to infect two human promonocytic cell lines, U937 and THP-1. At the time of peak reverse transcriptase activity, cells were divided into the following groups: non-stimulated cells; cells stimulated with 400 U/ml interferon (IFN$_\gamma$); and cells stimulated with 100 ng/ml lipopolysaccharide (LPS). Non-infected cells were treated identically and served as controls. After 24 hr, total RNA was extracted, electrophoresed and subjected to Northern blot using probes consisting of cDNA for HLA-DR and for cyt-b. An actin probe was used as an internal control.
Results. Expression of HLA-DR and cyt-b mRNAs were decreased in non-stimulated, HIV-infected cells. IFN$_\gamma$ stimulation resulted in increased levels of HLA-DR and cyt-b mRNAs; however, these levels were diminished in the infected vs. the non-infected cells. LPS had no effect. Actin mRNA was equivalent in all groups and was not affected by either infection or stimulation.
Conclusion. HIV infection caused down-regulation of two markers of mononuclear cell activation at the transcriptional level. These alterations may play an important role in the pathogenesis of cellular immune dysfunction. IFN$_\gamma$ partially reversed the HIV effects.

C.522

MUCOSAL IMMUNE SYSTEM IN HIV1 INFECTION; ACTIVITY OF SPECIFIC ANTIBODIES IN PAROTID SALIVA

Ze'ev Trainin*; Archibald, D.**; Purth, P.**; Hamel, D.J.*; Di, S.**; McLane, M.F.*; Essex, M.* *Harvard Univ., Boston, MA. **Univ. of Maryland, Baltimore, MD, U.S.A.

Objective. To look for qualitative and quantitative properties of the specific antibodies in the parotid saliva of HIV1 infected people.
Methods. Serum and parotid saliva was collected from 19 HIV1 infected people of different clinical status; CDCII (7), CDCIII (3), CDCIV (9). The immunoglobulins IgA, IgG and IgM were seperatly eluted from the sera and saliva. The serological techniques used were the western blot, ELISA and neutralization test.
Results Specific antibodies (Ab) to the HIV1 were found in the sera and saliva of all the people tested. They were found positive in both immunoblotting and ELISA. The immunoblotting test revealed Ab's to all major HIV1 antigens (env, pol and gag). The predominant Ig class of specific Ab's toward env proteins in the serum was IgG, while in the saliva it was IgA class. Moreover IgA antibodies were found by ELISA in 14 of 16 salivas tested, while IgG antibodies were found in only 6 of 12 saliva samples. The level of Ab's to the env antigens in the sera and salivas varied widely. Comparing level and class of Ig's, we could not find any significant differences between the groups of asymptomatic, CDCII and AIDS affected people. The saliva IgA antibodies toward the env proteins revealed less reactivity compared to the serum IgA, in 12 of 14 samples tested. The relative lower reactivity ranged from 2 to 65 times lower (mean=11). Neutralization assay revealed positive reaction in 3 of 7 sera tested in rather low titers (1:10-1:100). None of the 9 tested salivas nor their respective IgA demonstrated neutralization activity.
Conclusion The current data revealed; A) Relatively low reactivity of saliva IgA compared to serum IgA. B) Lack of neutralization activity in the HIV1 antibodies of salivas. C) No correlation could be established between antibody reactivity and the 3 CDC HIV1 categories. These findings might suggest that the mucosal immune response in HIV1 infected people is impaired long before any pathognomonic symptoms of AIDS occur.

C.523

EARLY DEVELOPMENT OF ANTI-HIV IgG

Wahren, Britta*; Trojnar, J.**; Sölver, E.*; Albert, J.*; Sandström, E.***; Broliden, PA.* and Wigzell, H.*
*National Bacteriological Laboratory, Stockholm, Sweden, **Ferring AB, Malmö, Sweden, ***South Hospital, Stockholm, Sweden.

Objective. To enhance the early seroreactivity in HIV infection/immunization.
Methods. Non-glycosylated 15-30 aa peptides covering the CD4 binding region of HIV were prepared by solid phase synthesis. All peptides were made to contain two cysteine residues in the same molecule and chemically oxidized. The sulphur bridge formed, restricts the peptides sterically.
Results. All patients (n=100) with established HIV-1 infection had an IgG1 response to one (JB-8p) of ten peptides representing the CD4 binding region. Subclasses IgG2, 3 and 4 appeared in 27, 60 and 35% respectively. In seroconverting persons (n=10) IgG1 and IgG3 antibodies to the peptide JB-8p developed within 3-4 weeks and parallelled total antiviral IgG. The JB-8 sequence represents the C-terminal of the putative gp120 CD4 binding region.
Conclusion. The 100% seroreactivity of HIV-infected individuals to a chemically modified peptide representing the CD4 binding region and the early serological response after primary infection implies a role for this peptide in vaccine development.

C.524

THE IMMUNE RESPONSE TO HIV-1 ENVELOPE PROTEIN INVOLVES BOTH ADCC AND CTL

Y. Rivière,[1] F. Tanneau[1], M. McChesney[1], A. Cordonnier[1], M. Emerman[1], M.P. Kieny[2], F. Sansonetti[1] and L. Montagnier[1]. [1] Institut Pasteur, Paris, [2] Trangène, Strasbourg, France.

Objective env protein specific cytotoxic effector cells, present in the peripheral blood of most HIV seropositive donors, have been characterised as either CD8+, MHC restricted or CD8- and MHC unrestricted. Phenotypic studies and analysis of antigen processing were used to define these effector cells.
Methods Uncleaved gp160 anchored in the plasma membrane, soluble gp120, an env precursor with deletion of the peptide signal or gp160 with deletion truncations were expressed in vaccinia. Autologous EBV transformed lymphoblastoids cells were infected with these recombinant vaccinia viruses and used as targets for primary cytotoxic effectors present in PBMC of HIV seropositive donors.
Results the predominant env specific cytotoxicity in most HIV donors is mediated by ADCC effectors cells : CD3-, CD4-, CD8-, CD16+ ; and lysis can be blocked by antibody to human IgG. ADCC effectors cells are able to lyse only target cells that express the env proteins at the cell surface as detected by surface immunofluorescence. However, CD8+ CTL are able to lyse target cells that do not express the whole env protein on the surface.
Conclusion in the heterogenous population of viral antigen specific effector cells in the pheripheral blood during HIV infection a major cytotoxic activity is env specific ADCC. However, in some individuals CTL activity or both ADCC and CTL activities are detectable.

C.525 TUMOR NECROSIS FACTOR (TNF) STIMULATES HIV1 TRANSCRIPTION IN HUMAN T CELLS

Israël, Nicole; Hazan, U.; Alcami, J.; Bachelerie, F., Arenzana-Seisdedos, F. and Virelizier, J.L.
Institut Pasteur, Immunologie Virale, Paris, France.

Objective. We have examined whether TNF might stimulate HIV1 transcription and we have analyzed the mechanism involved.
Methods and results. We transfected J. Jhan cell line (a subclone from Jurkat T cell line) with the plasmid LTR HIV.CAT which contains the HIV1 LTR sequences upstream of the bacterial CAT gene. CAT activity was consistently increased 5 fold when transfected cells were treated with TNF. Such transactivation was enhanced : more than 20 fold when the NRE region of the LTR (upstream of -138) was deleted. More precisely we show here that the enhancer (-108, -75) element, previously described to bind NF-kB, is necessary for TNF activation of the heterologous tk promoter. However flanking sequences of this region are important for full transactivation. Using bandshift assay, we show that this increased expression is accompanied by the induction or activation of an NF-kB-like transcription factor. We show also that PHA and PMA have synergistic effects with TNF. Such a synergy was not due to superinduction or activation of this transcription factor and may be due to upregulation of TNF receptors by PHA or PMA.
Conclusion. Since TNF is secreted during most immunological and inflammatory reactions and has been indeed detected in the serum of AIDS patients, our observations suggest a possible rôle for TNF in the pathogenesis of AIDS through activation of HIV genome transcription

C.526 HIV-1 AND HIV-2 SPECIFIC IgG SUBCLASS REACTIVITY TO env AND gag PEPTIDES

Broliden, Per Anders*; Outtara, A.S.**; Sølver, E.*; Trojnar, J.***; Norrby, E.**** and Wahren, B.*
*National Bacteriological Laboratory, Stockholm, Sweden, **Institut Pasteur De Cote D'Ivoire, Abidjan, Ivory Coast, ***Ferring AB, Malmö, Sweden, ****Karolinska Institute, Stockholm, Sweden

Objective. To evaluate and compare the HIV-1 and -2 specific IgG subclass reactivity to selected peptides.
Methods. Peptides representing five immunodominant regions of the HIV-1 and -2 env and gag proteins were used as antigens in IgG subclass ELISA assays. Sera from HIV-1 and -2 infected individuals were analysed.
Results. IgG1 was the dominant anti HIV-1 subclass and was detected in 100% of the sera. The HIV peptides representing gp36-41 elicited the highest frequency of reactivity of all subclasses. The reactivity to the gp120 peptide was mainly restricted to IgG1 or 1+3. A high IgG1+3 reactivity was also seen directed to peptides representing the putative hypervariable loop region of gp120. Subclass response to peptides representing regions of p17 and p15 was restricted to IgG1+4 and IgG1+2 respectively. Sera from HIV-2 infected individuals showed a 90-100% reactivity to the corresponding HIV-2 peptides. Crossreactivity was more frequent in the HIV-1 group to HIV-2 peptides than vice versa.
Conclusion. A differential restriction of the IgG subclass response was seen to regions of HIV representing the major structure proteins. The IgG3 response to envelope-representing peptides indicates frequent gp120 stimulation and capacity for neutralization.

C.527

C.528 RELATIONSHIPS BETWEEN THE PHYSIOLOGICAL FUNCTION OF CD4 AND ITS ROLE AS THE HIV RECEPTOR

Quentin J Sattentau*; Merkenschlager, M**; Healey, D.*; Truneh, A***; Arthos,J.***; Sweet,R.***; Beverley,P.C.L.**
* The academic Dept. of G-U Medicine, UCMSM,London,UK
** HTIG, ICRF, UCMSM, London, UK
*** Smith, Klein and French Laboratories, King of Prussia, PA, USA

Objectives To define with the use of monoclonal antibodies (mAbs) to CD4 and their anti-idiotypes those sites on the CD4 antigen important in the physiological functions of this molecule in relation to their role in HIV reception.
Methods The amino acid residues essential for the binding of a number of CD4 mAbs has been determined using forms of the CD4 antigen containing point mutations. These mAbs have also been used to probe the function of the CD4 antigen in terms of its HIV binding capacity and role in T-cell activation.
Results We have defined those CD4 mAbs which react with residues most similar to the amino acids which gp120 requires for binding. These mAbs are highly effective at inhibiting T-lymphocyte responses to soluble recall antigens and mitogens in a soluble form, but are also capable of enhancing T-cell responses when cross-linked with CD3 mAbs.
Conclusions Antibodies against CD4 which inhibit HIV-induced syncytium formation require residues very similar to those required by gp120 for binding to CD4, and are also highly effective at modulating T-cell activation. We therefore conclude that the regions of CD4 reactive with HIV gp120 are important in the physiological function of CD4.

C.529 HIGH LEVELS OF CELL-ASSOCIATED IL-1 IN CIRCULATING MONOCYTES FROM HIV-INFECTED INDIVIDUALS.

Weiss, Laurence; Haeffner-Cavaillon, N.; Laude, M. and Kazatchkine M.D.
Unité d'Immunopathologie, Hôpital Broussais, Paris, France.

Stimulation of normal monocytes results in transcription of IL-1α and β genes and accumulation of cell-associated IL-1. Some but not all IL-1 inducers further trigger the extracellular release of IL-1β. We have examined the production of cell-associated IL-1 in vivo and that of cell-associated and extracellular IL-1 in vitro in 30 infected individuals and 30 non-infected controls. Cell-associated IL-1 activity assessed using a comitogenic thymocyte assay was significantly increased in patients with AIDS (80.6 ± 19 U/ml (mean ± SEM ; n = 14) and HIV+ oligosymptomatic individuals (32.9 ± 10.2 U/ml ; n = 16) as compared with normals (4.4. ± 1.6 U/ml ; n = 30). Cell-associated levels of IL-1α and β antigens were also elevated in HIV+ individuals. Serum-free culture of monocytes from HIV+ individuals in the absence of IL-1 inducers resulted in spontaneous release of IL-1 activity, IL-1β and α antigens. No IL-1 activity was released by cells from normal individuals cultured under the same conditions. LPS-stimulation of monocytes from HIV+ patients induced the release of both IL-1 and whereas cells from normal individuals exclusively released IL-1β. However less IL-1 activity was released by LPS-stimulated cells from HIV+ patients as compared with normals. Thus, HIV-infection is associated with the chronic stimulation of monocytes to produce IL-1 in vivo and an alteration in the intracellular pathways regulating the extracellular release of IL-1α.

C.530 SPECIFICITY OF CD4$^+$ T CELLS FROM CYNOMOLGUS MACAQUES IMMUNIZED WITH HYBRID HIV P24:Ty VIRUS LIKE PARTICLES

Mills, Kingston*, Barnard, A*, Adams, S**, Kingsman, S**, Kingsman, A** and Kitchin, P*. *NIBSC, Blanche Lane, South Mimms, Herts EN6 3QG, UK. **British Biotechnology Limited, Oxford, UK.

Objective. To assess the ability of a novel antigen presenting system to generate T-cell responses to HIV gag proteins in primates.
Methods. Four pairs of cynomolgus macaques were immunized with a recombinant HIV-1 gag protein expressed in yeast as hybrid P24:Ty virus like particles (VLPs). Animals received 3 i.m. injections, at 6 week intervals, of 50 or 500µg of P24:Ty-VLPs with or without alum as adjuvant. Proliferative responses of peripheral blood lymphocytes were tested at 2 week intervals. CD4$^+$ T-cell lines and clones were established and assessed for antigen specificity.
Results. Lymphocyte proliferative responses to P24:Ty-VLPs and control Ty-VLPs were detected in all animals as soon as 2 weeks after immunization. Responses were significantly greater in animals given the antigen with alum. Lymphocytes from these animals also gave a significant response to recombinant gag alone or to whole HIV. Proliferation and IL-2 release by T-cell lines and clones in response to synthetic peptides from the P24 sequence demonstrated the presence of CD4$^+$ T-cell epitopes on HIV-P24.
Conclusion. Hybrid HIV P24:Ty VLPs are a useful antigen presenting system for the generation of proliferative T-cells to HIV gag proteins and have allowed us to identify determinants on P24 recognised by CD4$^+$ T cells from cynomolgus macaques.

C.531

T CELL RECOGNITION OF HIV PEPTIDES. R.D. Schrier, C.A.Wiley, J.W. Gnann Jr., R. Landes, C. Lockshin, D. Richman, A. McCutchan, M.B.A. Oldstone, J.A. Nelson. Research Institute of Scripps Clinic, La Jolla, CA, University of California, San Diego, La Jolla, San Diego V.A. Medical Center, San Diego, U.S.A.

Because T-cell responses are critical for defense against viral infections, a series of synthetic peptides derived from the predicted sequence for human immunodeficiency virus (HIV-1) proteins gp41, gp 120, gag and viral polymerase were employed to test the T-cell proliferative response of HIV-1 seropositive individuals. Ninety percent (27/30) of HIV-1 infected donors from various clinical categories had sensitized cells that proliferated in response to at least 1 of 21 HIV peptides tested. Cells from HIV seronegative controls did not proliferate (0/9) in response to these HIV peptides. Individuals with fewer clinical manifestations of HIV-1 disease responded to a greater number of peptides and the number of peptides recognized also correlated with absolute number of CD4 positive cells. Response patterns differed considerably among individuals, and some peptides stimulated proliferation in many (48%) HIV infected donors (peptides gp41-2, and pol-3), whereas another peptide elicited no T-cell response in any donor tested (peptide gp120-8).

We have begun to investigate the basis for individual heterogeneity of T lymphocyte proliferative responses. Peptide structure and HLA class II determinants both influenced patterns of lymphocyte responses. Reactivity correlated with peptide size, the presence of and secondary structure and lack of reverse turn potential. HIV infected lymphocyte donors were HLA typed to examine the influence of the MHC on T lymphocyte proliferation. Analysis of the frequencies of individuals reacting to specific peptides, when compared to the allele frequencies in the population at large, indicated association of some responses to DR alleles. Genetically determined variations in responses could influence disease progression and may have to be considered for vaccine design. This work was supported by USPHS grants AI-07007 and NS-12428 (MBAO), funds provided by the State of California and allocated on the recommendation of the Universitywide Task Force on AIDS (RS, JN, DR, AM), USPHS training grant NS-07078 (JG) and the U.S. Army Medical Research and Development Command under Contract No. DAMD17-88-C-8103.

C.535

STUDY OF THE FUNCTION AND STRUCTURE OF IL2-R IN HIV-INFECTED SUBJECTS. Y. LUNARDI-ISKANDAR, E. SPANAKIS, C. JASMIN, V. GEORGOULIAS. Oncogénèse Appliquée (INSERM U268), Hôp. Paul Brousse, 14-16 av. P.V. Couturier, 94804 Villejuif, France.

Objective : To elucidate the mechanisms responsible for the low proliferative responses of T cells during HIV infection.

Methods : PBL were obtained from 7 AIDS, 5 LAS and 8 asymptomatic seropositive patients as well as from 8 normal controls. Surface Tac expression was studied by indirect immunofluorescence whereas the affinity and the structure of IL2-R were evaluated by binding and cross-linking of ^{125}I-rIL2 under high affinity (h.a.) conditions using 3-day PHA-activated cells. Northern blot analysis was used to determine the expression of the Tac gene.

Results : LAS and AIDS patients displayed fewer (1444±884 and 1070±870 sites/cell, respectively) h.a. binding sites and a significantly (p<0.1) higher (188±34 pM, and 120±88pM, respectively) kd than asymptomatic subjects (B.C=3003±782 sites/cell : kd=58±18pM) and normal controls (BD=2842±844 sites/cell : kd=74±17pM). In some patients, cross-linking experiments revealed the absence of the p75 chain of IL2-R. The expression of the Tac gene although present is decreased in comparison to normal cells. HIV infection of T cells in vitro, before their mitogenic activation, resulted in a decreased expression of the Tac molecule and in a time-dependent decrease of h.a. binding sites as well as in an increase of kd. In vitro infection of already activated cells was followed by a time-dependent decrease of the h.a. binding sites. One hour cell incubation with infectious, but not non-infectious, HIV resulted in an increase of the kd (88%) which remained unchanged for 3 days, and which could be prevented by an incubation with anti-CD4a mAb before infection. The rapid increase of the kd of IL2-R is not due to a decreased expression of the Tac gene since 5hr post-infection cells still express considerable amounts of Tac mRNA.

Conclusions : The described functional and structural abnormalities of IL2-R are due to HIV infection and could be involved, at least partly, to the impaired proliferative responses of T cells during HIV infection.

C.536

IMPAIRMENT OF HUMAN NEUTROPHIL (PMN) FUNCTION IN VITRO BY HIV-1 AND GP 160
Bai Xin-Qing*, Numazaki, K.*,**, Lyras, A.**, Wainberg, M.A.*,** and Mills, E.L.**
*Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, Montreal, Quebec, Canada, **McGill University - Montreal Children's Hospital Research Institute, Montreal, Quebec, Canada

In addition to opportunistic infections, individuals (especially children) infected with HIV-1 may also be at increased risk for bacterial infections due to pyogenic organisms such as S.aureus. The PMN of HIV-infected persons have been reported to have impaired bactericidal activity and chemotaxis but a normal respiratory burst. Objective. To study the effect of ultraviolet-inactivated (UV) HIV-1 or purified envelope component gp 160 on PMN function in vitro. Methods. Isolated PMN were exposed to UV-HIV-1 (3 x 10^6 CPM RT assay/10^5 PMN) and gp 160 (2.5 ug/10^5 cells). Functional capacity of stimulated PMN was measured using luminol enhanced chemiluminescence (CL) and chemotaxis. Results. UV-HIV-1 and gp 160 reduced opsonized zymosan and FMLP stimulated CL by 20-30% but had no effect on PMA-stimulated CL. The effect of UV-HIV-1 and gp 160 on chemotaxis are in progress. Conclusion. The data suggest that the immunosuppressive activity of noninfections HIV-1 may contribute to the phagacytic cell defect observed in infected patients.

C.538

ANTI-IDIOTYPIC ANTISERA TO ANTI-CD4: THEIR SPECIFICITY AND ANTI-HIV POTENTIAL

Donald Healey*, Broadhurst, K,* Beverley, P*† and Sattentau, Q*.
* Middlesex Hospital, London, UK. ** ICRF, London, UK.

OBJECTIVE: To investigate the cross-reactive nature of anti-idiotypic reagents to Leu3a anti-CD4 and to evaluate their potential to inhibit syncytial formation between CD4+ c8166 cells and HIV RF.

METHODS: Lou rats, Balb/c and SJL mice were immunised with Leu3a anti-CD4 antibody coupled to KLH, administered intraperitoneally with complete freunds adjuvant. The resulting antisera were screened for their capacity to inhibit the binding of Leu3a, and other anti-CD4 antibodies to CD4+ Supt1 cells.

RESULTS:

IDIOTYPE	RECIPIENT	ANTI-IDIOTYPE ACTIVITY					
		Leu3a	RFT4	MT310	NUTH-1	L201	MT151
	Rat	+++	-	+++	-	+++	-
Leu3a	Balb/c	+++	+	+++	++	+++	+
	SJL	+++	-	-	-	-	-

CONCLUSIONS: The anti-idiotypic profile induced by Leu3a is dependent on the choice of recipient, therefore, the suitability of the anti-idiotypic approach to HIV therapy will be reflected by the genetic background of that recipient. None of the anti-Leu3a antisera contained anti-HIV potential.

C.539

C.540

PRELIMINARY EVALUATION OF A RECOMBINANT SIV-ENVELOPE PEPTIDE FOR USE AS A DIAGNOSTIC FOR HIV-2 INFECTION.

Michael Lennick, A. Wilde, P. J. Kanki*, and G.A. Beltz,
Cambridge BioScience Corporation, Worcester, MA, USA, *Harvard AIDS Institute, Boston, MA, USA.

Objective. To develop a recombinant peptide for use in an HIV-2 immunoassay.

Methods & Results. We have cloned several unique restriction fragments from the SIV envelope coding region into *E. coli* expression vectors. When tested in Western blots, three of the expressed proteins were capable of detecting all of the known HIV-2 positive sera from a well characterized panel of West African samples. One of the recombinant proteins, SIV-env, represents about 35% of the total sequence of the SIV envelope glycoprotein; the C-terminal one-third of the external envelope glycoprotein plus the N-terminal half of the membrane-associated domain. SIV-env was expressed to high levels in *E. coli* and was isolated to greater than 95% purity from inclusion body preparations. We have used the purified SIV-env to construct an experimental ELISA for HIV-2. In preliminary studies, we have found this immunoassay capable of specifically detecting all of the known HIV-2 positive samples in our panel.

Conclusion. Preliminary results demonstrate the potential of SIV-env for use as a tool for the diagnosis of HIV-2 in humans.

C.541

BRONCHOALVEOLAR LAVAGE (BAL) MONONUCLEAR SUBSET CELLS, AT DIFFERENT STAGES OF HIV INFECTION.

May, Thierry; Kohler,C.; Amiel,C.; Faure,G.; Gerard,H.; Canton,Ph.
CHU - Nancy - FRANCE

Objective: Long term effects of HIV infection on BAL mononuclear cells, were evaluated in a cohort of 88 patients, at different stages of HIV infection.

Methods: These patients were divided in 4 groups, according to clinical stages: group A = CDC II and III; group B = ARC; group C = AIDS except pulmonary infections; group D = AIDS including pulmonary infections. The mean age was 37+5 years, and sex ration 6:1. Smokers represented 80%.
Biological investigations on BAL cells included cytological and immunological strudies, using classical indirect immunofluorescence techniques.

Results are summarized in this table:

group	A	B	C	D	control
cellularity (10^3/ml)	607+102	803+145	287+49	313+52	213+134
macrophages (10^3/ml)	506+83	687+167	235+50	224+45	202
% macrophages	82+5	83+8	78+5	71+5	89
% lymphocytes	15+4	12+6	18+2	24+4	7
%CD4+cells in BAL	10	4	5	2	35
%CD8+cells in BAL	40	44	42	40	22
CD4/CD8 on PBL**	0,76	0,27	0,42	0,12	2+0,5
CD4/CD8 in BAL	0,25	0,09	0,12	0,05	1,59

**PBL=peripheral blood lymphocytes

Conclusion: Even at early stages, HIV infection induces significant modifications on BAL cells: in groups A and B, macrophages and CD8+cells are increased, and there is a rapid and profound defect of CD4+cells.

C.542

ANALYSIS OF EXPRESSION OF $\gamma\delta$-T CELL RECEPTOR AND $CD3^+CD4^-CD8^-$ PHENOTYPE BY LYMPHOCYTES FROM HIV-1 SEROPOSITIVE AND SERONEGATIVE HOMOSEXUAL MEN IN THE BALTIMORE MACS.

Margolick, Joseph, Scott, E., and Saah, A., The Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA

Objective: To determine the degree to which the increase in calculated $CD3^+CD4^-CD8^-$ (double negative; DN) lymphocytes associated with HIV-1 seropositivity (Margolick et *al*., Clin.Immunol.Immunopathol., in press) is due to an increase in lymphocytes expressing the $\gamma\delta$ T-cell receptor (TCR).

Methods: Peripheral blood lymphocytes from 17 SN and 19 SP (17 AIDS-free) homosexual men were analyzed by 2-color flow cytometry using the following combinations of fluorescein (FITC)-or phycoerythrin (PE)-conjugated monoclonal antibodies: 1) CD3-FITC; 2) CD4-PE/CD8-FITC; 3) CD3-FITC/CD4-PE + CD8-PE; 4) CD3-PE/pan-δ-chain-FITC; and 5) CD8-PE/pan-δ-chain-FITC. Calculated DN (CDN) were determined by the formula %CD3 - (%CD4 + %CD8).

Results: Compared to SN, SP had increased proportions of calculated DN (3.5% vs. 1.5%; p=0.03 by 2-sample T test), as expected, and δ^+CD3^+ cells (3.7% vs. 2.3%; p=0.05). Directly measured DN (DDN) cells ($CD3^+CD4^-CD8^-$ in antibody combination #3) were also increased in SP, but not significantly (4.6% vs. 3.5%; p=0.13); however, %DDN was significantly correlated with %CDN (r=0.484; p=0.003). DDN cells not expressing the δ chain (%DDN - (%δ^+CD3^+ - %δ^+CD8^+) were present in both SP and SN (2.3% vs 1.6%; p=0.15).

Conclusions: These data suggest that 1) the increase in calculated %DN lymphocytes which is associated with HIV-1 seropositivity is at least partly due to an increase in lymphocytes expressing the DN phenotype and the $\gamma\delta$-TCR; and 2) changes in other lymphoid populations, such as a decline in natural killer cells, may also contribute.

C.543

USE OF AUTOLOGOUS CD4+ T CELLS IN THE ASSAY OF HIV-1-SPECIFIC CYTOTOXIC T CELLS (HIV-CTL)

Izaguirre, Carlos A. and Drouin, J. Department of Medicine, University of Ottawa and Ottawa General Hospital, Ottawa, Ontario, Canada.

Objective.- We have reported that the anti-HIV drugs castanospermine (CSP) and dextran sulfate (DS) induce the regeneration, within 5 days, of CD4+ T cells in lectin-stimulated cultures of blood lymphocytes from HIV+ patients. Based on this observation, we describe a method that permits the use of autologous CD4+ T cells as targets in the assay of HIV-specific cytotoxic T cells (HIV-CTL). Method.- Blood mononuclear cells cultures are started with Con A, IL-2, to which are added CSP or DS (25 μg/ml). On day 3 the CD4+ cells are separated from CD8+ T cells by staining with anti-CD8 (OKT8) antibody, incubation with goat antimouse antibody conjugated to magnetic particles and separation of CD8+ T cells using a magnet. The separated cells are cultured for 3 to 4 days in a medium containing IL-2 and CSP or DS (25μg/ml). A day before the CTL assay, the CD4+ cells are infected in vitro with prototype HIV-1 virus and incubated for 18 hours in a medium without anti-HIV drugs. The following day the CTL assay is carried out. Results. A systematic analysis of the method demonstrated that the proposed assay is reproducible and reliable. We have used autologous CD4+ T cells in the cloning of HIV-CTLs (3 experiments) and in the study of the HIV-CTL response in 5 HIV+ patients. A more detailed study of patients is now being carried out. Conclusion. The method proposed here should be of value in studies of the HIV-CTL response in the clinical as well as the research laboratory.

C.544

CHEMICAL SYNTHESIS OF CHIMERIC PEPTIDES AND PROTEINS FOR IMMUNOLOGICAL PURPOSES.

Mascagni Paolo*; Sia, D.Y.**; Toth, G.K.*; Gibbons, W.A.*; Hasheim, L.R.**; Kent, S.*** and Coates, A.R.M.**
* The School of Pharmacy, London, UK.
** The London Hospital Medical College, London, UK.
*** California Institute of Technology, California, USA.

Objectives. To chemically synthesize a 104 amino-acid long peptide corresponding to the 273-377 sequence C terminal half of HIV-1 gag p24, and the hybrid peptides p24 (T-epitope)-linker-env (B epitope) 42 mer and p24 (273-377)-linker-env (B-epitope) 138 mer.
Methods. The three polypeptides were synthesised using highly optimised custom protocols on an ABI-430 synthesiser. Crude peptides were dialysed and purified by a combination of reverse phase, size exclusion and ion-exchange HPLC. Quality control included amino-acid analysis, protein sequencing, SDS-PAGE and IEF gel chromatography and FAB-mass spectrometry.
Results. The synthesis of the 104 mer peptide yielded three grammes of crude peptide-resin. After purification 20% (w/w) of the cleaved peptide was obtained and had a chemical composition which was consistent with the expected amino-acid sequence. Similar yields of homogeneous material were obtained for the chimeric peptides. Immunisation of mice with the peptide and proteins induced antibodies to HIV core and envelope proteins.
Conclusions. This work suggests that the chemical synthesis of long peptides is feasible and may have application in vaccine development.

C.545

A CHEMICALLY SYNTHESISED 104-MER PEPTIDE OF THE C-TERMINAL HALF OF HIV-1 P24 SUCCESSFULLY USED AS AN HIV IMMUNOGEN

Hasheim, Lars R.*, Mascagni, P.**; Sia, D.Y.*; Tooth, G.K.**; Gibbons, W.A.** and Coates, A.R.M.*
*The London Hospital Medical College, London, UK; **London School of Pharmacy, London, UK.

Objective. To investigate the immunological properties of a chemically synthesised C-terminal half (104 residues) of HIV-1 p24 core protein.
Methods. The 104-mer peptide was prepared using an Applied Biosystems 430-A synthesiser employing t-Boc chemistry and used in purified form in the subsequent work. T-cell response was studied by in vitro proliferation of antigen-restimulated spleen cells from mice previously primed with the peptide. Mice and rabbits were immunized subcutaneously with approx 10μg peptide in Freund's incomplete adjuvant. Murine monoclonal antibodies were made using NSO myelomas as partner. Antibody activity in sera from HIV-1 haemophiliacs and experimental animals was tested in ELISA and Western blot with the 104-mer and HIV-1 proteins.
Results. A dose-dependent proliferative T-cell response in mice was found using the 104-mer as antigen. Antibodies from mice and rabbits reacted strongly with the 104-mer immunogen and also with the HIV gag proteins p24 and p55. Conversely, sera from HIV-1 seropositive humans reacted with the 104-mer.
Conclusion. The synthetic 104-mer peptide elicited an anti-HIV-1 T- and B-cell response, indicating that some important epitopes are shared between this chemically synthesised molecule and the natural viral gag proteins. Thus, immunologically useful HIV-proteins can now be prepared by chemical synthesis.

C.546

MHC CLASS I-III ALLOTYPES IN PATIENTS WITH DISSEMINATED KAPOSI SARCOMA (KS), ARC/WRS, AND IN NORMAL CONTROLS

Georg Plum; H. Krickeberg; E. Siebel; C. Bendick; H. Rasokat; G.Mauff; and the ARC-IVIG- Study-Group Cologne/Berne
Depts. of Medical Microbiology, Virology, Internal Medicine II, Dermatology, Pathology, Biostatistics, Univ. of Cologne, FRG; Blood Transfusion Service, City Hospital, Cologne, FRG; Central Laboratory, Swiss Red Cross, Berne, Switzerland

Objectives: *Major histocompatibility complex* (MHC) class I and II (=HLA-A,B,C,DR) association in HIV-infected patients has been controversial. Of the MHC coded complement components C2, BF, C4A/C4B (MHC class III) allotypes of C2 and C4 have not yet been reported. C4 allotypes appear of major immunogenetic relevance for their potential differences in virus neutralizing potency. In the present study 30 ARC/WR5 patients from the ARC-IVIG project (cf.: *Schrappe-Bächer et al.*), 30 patients with disseminated KS, and 160 HIV-negative control individuals were compared for MHC class I to III allotypes.
Methods: All individuals were of West German origin. Diagnosis of ARC and KS (CDC and WR criteria) was done by clinical and laboratory parameters, MHC testing by standard methods: microlymphocytotoxicity assay for HLA-A,B,C,DR, electrophoretic and haemolytic tests for class III allotypes, Western blots with poly- and monoclonal antibodies for C4A/B.
Results: An *increase* in frequency ($p \leq 0.05$) was observed between ARC/WR5 patients and controls for HLA-B35/CW4, DRW14, a *decrease* for B16, CW6/DR7. In KS CW6 was more frequent than in ARC/WR5 patients. However, values were not significant if corrected for the number of tested antigens. No significant differences were seen between KS and ARC patients or controls for class III allotypes, nor for the previously reported associations e.g. of B8, DR2, DR3, and especially DR5, including the DR5-splits DRW11, 12 .
Conclusions: The results indicate lack of strong MHC-association with the investigated antigens in West German Caucasoids. The contrast of our data to previous findings for classical as well as disseminated KS supports the hypothesis of ethnic dependence of HIV-related diseases.

C.547

CARBOHYDRATE-DEPENDENT EPITOPES OF HIV-1 GP120

Bolmstedt Anders*; Sjöblom I.*; Åkerblom L.**; and Olofsson S*.
*Department of Clinical Virology, University of Göteborg, Göteborg,
**Department of Vet. Microbiology/Virology Uppsala, Sweden.

Objective. Carbohydrates may decrease or increase the antigenic activity of viral glycoproteins. In the heavily glycosylated HIV-1 gp120 the carbohydrate content represents one half of the molecular weight. The aim of this study was to identify regions on gp120 where N-linked carbohydrates exert modulating effects on the antigenic activity.

Methods. Secreted gp120 was covalently linked on microtiter plates and exposed to neuraminidase and increasing concentrations of periodate. As a control of sequential removal of peripheral monosaccharides an enzyme-linked lectin assay was used. The alternation in antigenicity, during the neuraminidase/periodate-treatment, was followed in ELISA with a panel of LAV-specific monoclonal antibodies.

Results. Removal of sialic acid and galactose from N-linked carbohydrates on gp120 resulted in significant increase in antigenic epitopes, in the N-terminal region, previosly masked by carbohydrates.

Conclusion. Our results demonstrate that some epitopes of gp120 are modulated by the carbohydrate complement. This phenomenon might, at least partly, be of importance for the ability of HIV to escape immune reactions.

C.549

MODIFICATION DE LA SECRETION D'INTERLEUKINE 1 PAR L'EPIDERME SAIN AU COURS DE L'AFFECTION VIH+

Dréno Brigitte*, Milpied B*, Dutartre H*, Litoux P*
* Clinique Dermatologique - Hôtel Dieu - Pl. A. Ricordeau - 44035 NANTES CEDEX 01 - FRANCE.

Objectif. Dans.le sang, la production spontanée d'interleukine 1 (IL1) augmente chez le patient VIH+ au début de l'affection, puis s'effondre au stade SIDA. Dans ce contexte, nous avons voulu vérifier si aux anomalies quantitatives des cellules de Langerhans (Lc) de l'épiderme s'associaient des modifications de la sécrétion d'interleukine 1 (IL1) épidermique produite normalement par les kératinocytes et les cellules Lc.
Méthodes. 33 patients VIH+ (11 au stade II, 10 au stade III et IVc1, 8 au stade IVc2 et 4 au stade IVd, ainsi que 5 témoins séro-négatifs ont été étudiés. Les biopsies cutanées ont toutes été réalisées en peau saine (face interne de bras) avec en plus un prélèvement en peau lésée (Kaposi) au stade IVd. Une technique d'immunofluorescence indirecte sur coupes congelées avec un anticorps anti IL1 (Biosys) et anti CD1 (IOT6, Immunotech) a été utilisée (chez les témoins Lc = 37,5 ± 7/mm longueur d'épiderme).
Résultats.
- au stade II et en peau lésée de Kaposi, la sécrétion d'IL1 épidermique est augmentée avec un nombre normal de cellules de Langerhans.
- au stade III et IVc1 elle est plus faible mais toujours supérieure à celle des témoins (Lc = 29,75)
- au stade IVd et IVc2, elle est effondrée avec chute des cellules Lc (12,2).

Conclusion. Ce travail confirme donc l'importance de l'atteinte fonctionnelle du système macrophagique cutané par le VIH.

C.550

SYNCYTIUM FORMATION AND DESTRUCTION OF CD4+ BYSTANDER CELLS COCULTURED WITH PERSISTENTLY HIV-INFECTED T-CELLS, AS DEMONSTRATED BY FLOW CYTOMETRY

Dominique Schols, R. Pauwels, M. Baba, J. Desmyter and E. De Clercq
Rega Institute for Medical Research, K.U.Leuven, B-3000 Leuven, Belgium

To investigate cell fusion and giant cell formation following fusion between HIV-1- or HIV-2-infected (HUT-78) cells and uninfected $CD4^+$ MOLT-4 (clone 8) cells, the two cell populations were mixed and cultured at 37°C, stained with the appropriate monoclonal antibodies (mABs) (FITC- or PE-conjugated), fixed and examined by flow cytometry.

At the moment that syncytium formation started, i.e. after 6-h incubation, the MOLT-4 cell number began to decrease and after a 24-hr incubation period all MOLT-4 cells had disappeared, as demonstrated with specific mABs to antigens expressed on either MOLT-4 or HUT-78 cells. The formation of giant cells and the concomitant disappearance of MOLT-4 cells was blocked by OKT4A/Leu3a mABs, and several parameters of cell fusion such as fusion index, percent of fusion inhibition and 50 % fusion inhibitory concentration of the mABs could be accurately determined.

This flow cytometric method can be readily implemented to evaluate any agents for their capacity to block cell-to-cell fusion and the subsequent destruction of the bystander target cells. Our observations also reveal a mechanism by which a few HIV-infected cells may gradually deplete the pool of uninfected $CD4^+$ cells *in vivo*.

C.552

DETECTION OF gp120 (HIV-1) AND ANTIBODIES TO DEFINED REGIONS OF gp120 IN HUMAN SERUM: CORRELATION WITH HIV-1 NEUTRALISATION

Moore, John and McKeating, J.A.(£)
Dept. Vet. Pathology, Glasgow, UK and
(£) Institute of Cancer Research, London, UK

We have developed ELISA-based methods for the detection of the HIV-1 surface glycoprotein gp120 in a subset of sera from HIV-infected individuals, and will describe data relating gp120 levels with those of p24 antigen, anti-gp120 antibodies and disease status. In this study, anti-gp120 antibodies are monitored using an extremely versatile, sensitive and specific ELISA that can use a wide range of sources of gp120 as capture antigen, including simple unpurified detergent extracts of divergent HIV-1 strains. We have also developed ELISAs that detect serum anti-gp120 antibodies (i) capable of blocking gp120 binding to CD4, and (ii) that bind to the type-specific neutralising loop (307-320). Data will be presented relating levels of these antibodies to neutralisation titre (eg. below).

Serum	Neut.Titre	Total gp120 Ab	CD4 blocking Ab	Anti-loop Ab
1	160	9000	270	250
2	80	9000	470	300
3	40	380	35	0
4	40	900	70	20
5	320	5700	680	600
6	160	9000	900	200

C.553

NATURALLY OCCURRING AUTO-ANTIBODIES TO CD4 AND THE MHC CLASS II MOLECULE IN HIV-INFECTED PATIENTS

Drabick, Joseph J., Baker, J., Layne, A., Sweet, R.*, Sadoff, J., and the Walter Reed Retrovirus Research Group, Walter Reed Army Medical Center, Washington, D.C., United States of America.
*Smith, Klein and French Laboratories, Philadelphia, PA., United States of America

The natural ligand for CD4 is the MHC Class II molecule. Antibodies to the CD4 binding site of HIV could theoretically cross-react with MHC Class II as both bind to CD4. Such anti-HIV binding site antibodies could also result in anti-idiotype antibodies cross-reactive with CD4. Western blots of EBV-transformed B cells rich in MHC Class II as demonstrated by a murine monoclonal were prepared. Sera from 25 HIV patients and 5 normal individuals did not demonstrate any reactivity suggesting cross-reactive antibodies do not exist or do so in such low titer as to be of no pathophysiologic relevance. Recombinant soluble CD4 was utilized in a direct EIA to determine if antibodies to CD4 are detectable in HIV patients. 3/20 (15%) patients reproducibly demonstrated reactivity compared to 0/5 normal individuals. EBV-transformed B-lymphocytes from patients continued to produce antibody to CD4 in vitro as measured by direct EIA and dot-ELISA. This indicates that a significant anti-CD4 response is present in HIV patients, possibly as a result of an anti-idiotypic response to pg120. These findings may have implications for the therapeutic use of soluble CD4.

C.554

CELL-MEDIATED LYMPHOPROLIFERATIVE RESPONSES BY ADULTS AND CHILDREN TO RECOMBINANT HIV ENVELOPE AND CORE PEPTIDES.

Borkowsky,Wm.;Moore,T.;Krasinski,K.;Papaevangelou,V. New York University Medical Center and Bellevue Hospital Center, New York, U.S.A.

Objective. To determine if recombinant HIV antigens elicit cell-medirted immune responses in infected adults and children and to compare these responses to those of seronegative individuals.
Methods. Lymphocytes from individuals at risk for HIV infection were cultured with recombinant HIV envelope and core (ENV & COR) antigens, as well as diphtheria and tetanus toxoids (DT & TT). Those with a stimulation index >3.0 were scored as responsive. The response rate among seronegative adults (NegAdu) and seropositive adults (PosAdu) was compared to that of seronegative children (NegPed), seropositive children (PosPed), and seroreverter children (PegPed).
Results. POSITIVE RESPONSES TO HIV AND RECALL ANTIGENS (%)

STATUS	ENV	COR	DT	TT
NegPed	3/32 (9)	4/32 (13)	12/29 (41)	20/29 (69)
PegPed	5/17 (29)	7/17 (41)	9/16 (56)	13/16 (81)
PosPed	9/35 (26)	12/35 (34)	8/31 (26)	16/31 (52)
NegAdu	7/28 (25)	4/28 (14)	18/25 (72)	24/25 (96)
PosAdu	1/13 (8)	3/13 (23)	6/13 (46)	10/13 (77)

Conclusions 1) Infected children are as likely to respond to ENV & COR as they are to recall antigens. 2) Infected children & seroreverting children are more likely to respond to HIV antigens than are noninfected children ($p<0.01$). 3) One fourth of high risk seronegative adults respond to HIV envelope antigen, indicating either antigen sensitization or nonspecificity.

C.555

ANTIGENIC ANALYSIS OF HIV-1 MAJOR CAPSID PROTEIN, p24.

Parekh, Bharat S., Balasubramanian, P. and Link, B.,
Clinical Division, Bio-Rad Laboratories, Hercules, CA 94547, U.S.A.

Objective. Although most HIV-1 seropositive individuals mount a significant immune response to p24, attempts to define one or more major antigenic sites on the molecule have not been successful. We report results of our experiments to identify antigenic site(s) on p24.
Methods. Long synthetic peptides, 50 to 70 residues in length, were synthesized from p24 sequences covering 80% of the molecule. These were used in an ELISA and in a competitive Western Blot assay to identify the immunoreactive peptides.
Results. Most specimens reacted with a C-terminal 70-mer peptide from p24, which included known reactive short sequences, gag329-350. Interestingly, some specimens that did not react with gag329-350, showed reactivity with the long peptide in ELISA and in a competitive assay. A few specimens also recognized another long peptide from p24 in addition to C-terminal 70-mer. A monoclonal antibody to p24 recognized a different peptide, confirming our previous observation that it does not compete with antibodies from seropositive individuals.
Conclusion. Major antigenic site(s) on p24 is contained in a C-terminal 70-mer peptide, while an additional site is present on a second peptide. The need to have long peptides to bind p24 specific antibodies indicate that the major antigenic site(s) recognized by human sera is conformation dependent.

C.556

CHEMOTACTIC ACTIVITY OF THYMOPENTIN (TP) ON LYMPHOCYTES FROM PATIENTS WITH HIV INFECTION.

Sampietro,Carmen*; Torre,D.*
Division of Infectious Diseases, Regional Hospital, 21100 Varese, Italy.

Objective. To determine chemotactic activity of TP on lymphocytes from HIV-infected patients. Recently,we showed defective chemotaxis of lymphocytes in patients with ARC and AIDS. In addition,thymic involution occurs early in HIV infection. TP is a immunomodulating drug isolated from bovine thymus that induces T-cell differentiation and has a direct hormonal effect on the functioning of mononuclear cells.
Methods. Lymphocytes from healthy controls and from patients with HIV infection were evaluated. Chemotaxis of lymphocytes was evaluated by a microchamber technique and the leading-front method was used to assess cell migration.
Results. Increased migration of lymphocytes from healthy controls was only observed at concentration of 0.5 mg/ml while decreased migration was observed at various other concentrations. When we preincubated lymphocytes from AIDS and ARC patients and from seropositives with 0.5 mg/ml of TP, further-decrease of chemotaxis was observed.
Conclusion. TP did not show to restore defective chemotaxis in HIV-infected patients. In our opinion, little immunological benefit can derive from the use of this drug in such patients.

C.557

ANTI-VIRAL AGENTS FOR AIDS: LYMPHOCYTE FUNCTION AS A MARKER OF RESPONSE.

Knox, Kirstine A., Peters, B., Pinching,A.J.
St. Mary's Hospital Medical School, London, U.K.

OBJECTIVE. To examine the value of lymphocyte function as a marker of response to Zidovudine and Active Lipid 721 chemotherapy by monitoring PHA induced proliferation.
METHODS. Patient and control peripheral blood mononuclear cells were prepared by density gradient centrifugation, resuspended at 10^6 cells/ml and cultured with PHA (0.5, 0.75, 1.0ug/ml) or RPMI for 72 hours at 37°C, 5% CO_2. Proliferation was determined by [methyl-^{3}H]thymidine incorporation. Cell populations had a viability of greater than 95%. Patients examined were stable without opportunist infection and were studied before and at 4 weeks therapy.
RESULTS. Preliminary studies show that after 4 weeks Zidovudine treatment PHA induced proliferation increases (mean cpm 16730 to 46040). On the other hand with AL721, proliferation decreases (mean cpm 32050 to 17040). All recorded patient values were depressed in comparison to the normal control group (mean cpm 00200).
CONCLUSION. In view of the limited value of CD4 counts as a quantitative marker of immune deficiency in AIDS, such functional studies may prove useful in monitoring established or novel therapies.

C.558

ACTIVATION OF COMPLEMENT BY HIV-INFECTED H9 CELLS

Gregory T. Spear ; June, B. A.; Landay, A. L. and Lint, T. F.
Department of Immunology, Rush Presbyterian St. Lukes Medical Center, Chicago, Illinois, USA.

Objective. To determine whether HIV-infected H9 cells activate complement (C) via the alternative (AP) or classical pathway (CP).
Methods. H9 cells were infected with HIV(RF) or HIV(CDC451). For AP activation, cells were incubated with human AB+ serum as a C source for 30 min at 37°C and washed. The cells were then stained with FITC-labeled goat anti-C3 F(ab')2, washed and analyzed by flow cytometry for C3 deposition. For CP activation, cells were first incubated with heat inactivated (HI) AIDS serum at various dilutions, washed, and then treated with C, stained and analyzed as above.
Results. Infected H9 cells do not bind C directly (AP activation), but do bind C after incubation with HI anti-HIV antibody from AIDS serum. Uninfected cells do not bind C The C3 deposition was inhibited by EDTA and EGTA indicating CP-dependent activation. Maximal C3 deposition occured with 1:4 to 1:16 dilutions of AIDS sera and was undetectable at dilutions of 1:256. Six out of six AIDS sera produced significant deposition while normal serum did not. Infected cells were more easily detected by staining for C3 than by staining for the human immunoglobulin on the surface, probably due to the amplification of the signal by the C cascade.
Conclusion. HIV does not induce H9 cells to become AP activators unlike some other virus-target cell combinations such as EBV infection of B cells. However, expression of HIV proteins on the surface of infected cells makes them susceptible to CP activation via antibody. This has important implications for the behavior of infected cells in vivo.

C.560

C.561

Evaluation of the role of the soluble CD8 receptor and IL2 receptor (IL2R) in patients with Human Immunodeficiency Virus infection.

L. Liebes+, A. Chachoua+, V. McAuliffe+, M. Brown*, P. Kung *, F. Valentine+ et al, +New York University Medical Center, NY NY 10012, and *T Cell Sciences, Cambridge MA 02139 USA

Objective: We evaluated the levels of soluble CD8 and IL2 receptors (IL2R) in patients with HIV infection. **Methods**: 63 patients with HIV infection and 7 normal controls were studied. Of these, 21 were assymptomatic seropositive (ASSYM), 19 had ARC, 13 had KS and 10 had AIDS with opportunistic infection. In previous studies the T8 protein has been shown to be released in direct proportion to the level of activation of T8 positive cells. Serum IL2R is a measure of the activated state of IL2R bearing cells. The levels of T8 and IL2R were compared with each other and with levels of plasma P24 antigen and T4/T8 ratios. Soluble CD8 and IL2R were measured using CellFree® Immunoassay kits from T Cell Sciences. T4/T8 ratios were determined by standard techniques. **Results**: Soluble CD8 levels in plasma of patients with ASSYM, KS, ARC, and AIDS were respectively 1029 ± 89, 1165± 131, 980 ± 118, and 717± 115 while normal controls were 508± 40 units/ml (Mean ± SE). IL2R levels in serum of patients with ASSYM, KS, ARC, and AIDS were respectively 783 ± 98, 970 ± 129, 1011 ± 119, and 1566 ± 157, normal controls were 188 ± 28 units/ml. Using chi-square analysis, comparing each group with normal controls, the majority of patients with AIDS, ARC, ASSYM and KS showed levels of both IL2R and soluble CD8 which were greater than the upper 95% value of normal ($p< 0.00001$). IL2R was better than T4/T8, %T4, and p24, for discriminating ASSYM from AIDS ($p< 0.0001$), ASSYM from ARC ($p< 0.002$) and ARC from AIDS ($p< 0.0001$). Using a combination of both receptors in each patient group, a formula was derived which predicted between normal and ASSYM patients. **Conclusion**: We conclude that there is an increase in soluble CD8 and IL2R in all patients with HIV infection compared to the normal control group. These data suggest that the measurement of levels of IL2R and soluble CD8 in HIV infected patients provides objective and quantitative parameters for clinical researchers studying changes in the immune status in ASSYM, ARC, KS and AIDS and may serve as a surrogate marker of disease in ASSYM patients.

C.562

AN INTERACTIVE RELATIONAL DATABASE FOR HIV AND THE IMMUNE SYSTEM

Hirons, G., Stanley, E. A., Hyman James M., and Nelson, G.
Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA.

Objective. To organize the complex, changing information about HIV and the immune system in a visually oriented, user-friendly, interactive system.
Methods. We are using HyperCard on an Apple Macintosh to create an interactive reference tool on HIV and the immune system. Information is presented on "cards," each of which contains a diagram and/or short description, as well as "buttons" which link the card to related cards. The "mouse" is used to click a button and move from card to card. For example, from the main card describing macrophages, the user can go to a card on the infection of macrophages by HIV, to a diagram of the chemical signals between immune-system cells and to other related subjects. Comment cards allow researchers to remark on contradictory results, difficulties with experiments, etc.
Results. We see one of the primary stumbling blocks to an understanding of how the immune system is slowly destroyed by HIV to be the difficulty involved in organizing the information from experiments and studies on HIV and then organize it within the context of the immune system. This continually expanding relational database can be used by newcomers to the field to get up to speed, by AIDS researchers who are not immune system experts to understand how the studies on HIV relate to the human immune system, and by immune experts to organize the latest information.
Conclusion. This HyperCard system, although still incomplete, will provoke AIDS researchers to develop new ways to organize the growing knowledge base. To obtain this experimental program send us three 2S/2D microdisks: in return we would like comments on its utility, structure, and content.

C.563

CIRCULATING INTERFERON-GAMMA IN HIV-1 INFECTION

Fuchs, Dietmar; Hausen, A.; Reibnegger, G.; Werner, E.R.; Dierich, M.P. and Wachter, H.
University of Innsbruck and Ludwig Boltzmann Institute of AIDS Research, Innsbruck, Austria

Objective. Progressive HIV-1 infection is associated with diminished in vitro production of lymphokines by T-cells upon antigenic and mitogenic stimulation. However, in vivo markers, e.g. neopterin, indicate hyperproduction of certain cytokines.
Methods. We measured serum concentrations of interferon gamma and neopterin in 43 HIV-1 seropositive individuals and 76 seronegative blood donors. A modified radioimmunoassay procedure for detection of interferon gamma was used with a detection limit of 18 U/l.
Results. 22 of the 43 seropositives exhibited increased serum interferon gamma concentrations. There was a significant association between serum interferon gamma concentrations and CDC-stages of the patients, CDC IV-C patients had the highest concentrations. Further, serum interferon gamma and serum neopterin concentrations were significantly correlated.
Conclusion. Circulating interferon gamma is increased in HIV-1 seropositives compared to seronegative blood donors. Diminished in vitro production of interferon gamma by T-lymphocytes on stimulation contrasts the in vivo findings.

C.564

β ENDORPHIN, A.C.T.H. AND CORTISOL RELATIONSHIP WITH AIDS

LE GOASTER Jacqueline *, ROUGEOT C. **, TEKAIA F. **, DRAY F. **, MONTAGNIER L. **, LE MAGNEN J. *** et al...
* Hôpital TROUSSEAU- Paris, ** Institut PASTEUR - PARIS, *** COLLEGE DE FRANCE - PARIS, FRANCE

Objective. Study of β. ENDORPHIN, A.C.T.H., CORTISOL plasma concentrations in homosexual HIV infected male groups.
Methods. 72 non drug-abuser males, 20-35 years old. 3 homosexual groups : AIDS=25, SERO+ =15, SERO- =15, one uninfected HETEROSEXUAL group as CONTROLS n=16. 2 blood samples dayly (8 am-5 pm).
β endorphin and A.C.T.H. were evaluated by radio-immunoassay and Cortisol by chromatography.
Data were analyzed by parametric and non parametric tests.
Results. 1) Both in AIDS, SERO+ and SERO- showed plasma β ENDORPHIN to A.C.T.H ratios are higher than equimolecular ratio of CONTROLS.
2) A loss of normal A.C.T.H-TOTAL CORTISOL coupling and relative rise of free CORTISOL level.
Conclusion. 1) The higher relative level of plasma β ENDORPHIN suggests a possible role of HIV products in opioid precursor (POMC) processing and its role in immunity.
2) The similar hormonal and neuroendocrin patterns of the 2 homosexual groups SERO+ and SERO- (living together) suggest either latent HIV infection in SERO- partners or other common factor to these two groups.
3) Possibility to take the higher ratio of β ENDORPHIN to A.C.T.H as, an early sign of HIV infection will be discussed.

C.565

C.566

SUPPRESSIVE EFFECTS OF IMMUNODEFICIENCY VIRUSES ON THE IN VITRO STIMULATION OF HUMAN LYMPHCYTES

Löwer, Johannes; Bonilla, J.; König, H.; Kurth, R.
Paul-Ehrlich-Institut, Frankfurt am Main, FRG.

Objective. Animal retroviruses exert a suppressive effect on the in vitro stimulation of lymphocytes. The equivalent effect of primate immunodeficiency viruses (HIV-1, HIV-2, SIVmac, SIVagm) on human cells should be studied and the responsible viral components should be identified.
Methods. In the lymphocyte stimulation assay, PBMCs are incubated with uv irradiated whole virus or with viral components (purified p24 and glycoproteins) and stimulated with PHA. After two days, the ^{3}H-thymidine uptake is measured. After solubilization, viral glycoprotein complexes are isolated by chromatography on lentil lectin and heparin columns.
Results. The most important variable in the lymphocyte stimulation assays is the origin of the human lymphocytes. Depending on the donor a more or less profound inhibition by inactivated HIV-1 can be observed. The extent of inhibition varies between 20% and 80%. However, the effect of HIV-2 and the SIVs is very small, often negligible. Purified glycoproteins give the same results.
Conclusion. The inhibitory effect of different immunodeficiency viruses in the lymphocyte stimulation assay may well be correlated to the pathogenic potential of these virus strains. Therefore, it may play a role in the pathomechanism of AIDS. In addition, lymphocytes of different donors are differently susceptible to this effect. Whether this observation can explain, at least in part, the differences in the time course of the disease in different individuals is an area of further investigation.

C.567

IDIOTYPIC RECONSTRUCTION OF HIV-1 GP41-GP120 INTERACTING STRUCTURES

Siccardi, Antonio G.; Andronico, F. and Erfle, V*. Dipartimento di Biologia e Genetica per le Scienze Mediche, Università di Milano, Italia, *GSF Munchen, Germany.

Objective. To understand the function of cross-reactive epitopes shared by HIV-1 gp120 and a human lympho-monocytic activation protein.
Results. A monoclonal anti-idiotypic antibody (9G5A) raised against M38 (anti-gp120 and anti-HELP) binds and competes M38, but also binds a bacterial fusion protein carrying the external domain of gp41. This couple of anti-idiotypic Mabs thus behave as "internal images" of two interacting structures located on gp41 and gp120, respectively. The two antibodies were tested in a very sensitive HIV neutralization assay and both proved to have a weak, but significant neutralizing activity. Since M38 defines an epitope shared by gp120 and an activation protein of human lympho-monocytes (HELP, human env-like protein), we propose that HELP might be involved in the virus penetration process as the receptor of gp41. Our data prove that an epitope of gp41, other than the fusogenic domain (which is not contained in the recombinant protein), is involved in the penetration mechanism and that it is a potential target for neutralizing antibodies.
Conclusion. The human env-like protein HELP might be the receptor for gp41 and be involved in the fusion process.

C.568

DIFFERENCES IN KILLING OF CD4 CELLS INDUCED BY HIV ISOLATES FROM ASYMPTOMATIC AND AIDS PATIENTS AS MEASURED BY Cr^{51} CYTOTOXICITY ASSAY.

Schechter, Mauro* **; Valentine, FT**. *Federal University, Rio de Janeiro, Brazil; ** New York University Medical Center, NY, USA.

OBJECTIVE: To examine differences in HIV-induced cell-contact mediated cell death using isolates from asymptomatic (AS) and AIDS patients (OI), employing a simple and reproducible assay.
METHODS: A cytotoxicity assay using as target cells Cr^{51} labeled CEM cells (CEM) or peripheral blood lymphocytes (PBL) from an uninfected donor. Effector cells (CEM or PBL) were infected with isolates from AS or OI. Effector to target ratios were adjusted relative to number of HIV infected cells, as judged by fluorescence. Results are expressed as percentage of maximal Cr^{51} release.
RESULTS: Cytotoxicity was prevented by Leu 3a (anti-CD4) Ab, but not by AZT and was not mediated by cell free medium from infected cells. Table 1 shows mean results obtained with isolates from 5 OI and 3 AS using CEM cells. Table 2 shows mean results with isolates from 8 OI and 8 AS, using PBL.

Table 1 CEM

% Specific Cr^{51} Release	
AS	OI
4%	35.6%

Table 2 PBL

% Specific Cr^{51} Release	
AS	OI
0.6%	14.6%

CONCLUSIONS: The data indicate that the cytotoxicity is dependent upon infected cell to uninfected cell contact. HIV isolates differ in their capacity to induce cell contact mediated cell killing, and these differences correlate with stage of disease.

C.569

QUALITY ASSESSMENT OF HIV ANTIBODY TESTS IN WEST GERMANY

Enzensberger,R.; Doerr,H.W.

University Clinics Frankfurt, Department of Medical Virology, FRG.

Testing for HIV antibodies is subject to continous technical improvement. Therefore permanent monitoring of the tests quality is a major requirement in HIV serology.
A panel of ten sera (three HIV-positive, one HIV-2 positive and six HIV negative) were sent to 77 German laboratories for a quality control test. Serum samples were assayed for HIV antibodies using 13 commercially available ELISAs (12 HIV 1-kits, 1 HIV 2-kit) IFA and Western blot.
The study revealed a high standard of efficacy of the tests as well as an excellent interassay reproducibility. The overall sensitivity of HIV-1 ELISA was 99.5% (96.6% - 100%). By IFA and Western blot the same level of accuracy was achieved. With the exception of the specific HIV-2 ELISA, HIV 2 antibody were consistently recognized only by the Abbott recombinant EIA (48.9% cross-reactivity). Western blot was even more sensitive (78% reactivity) mostly due to the p24 protein band. In an additional series of 43 sera of weak reactivity in our laboratory (60% renal transplant recipients) Western blot and IFA were definitely more specific (91.2%/97%) than most ELISAs (18.9%-100%), emphasizing the importance of confirmatory testing for all equivocal results.

C.570

IN VITRO LYMPHOCYTE PROLIFERATIVE RESPONSES (LPR) IN HIV INFECTED PATIENTS RECEIVING ZIDOVUDINE (ZVD)

Eric OKSENHENDLER, C. RABIAN-HERZOG, J. COLOMBANI, M. SELIGMANN - Hôpital St Louis - Paris - France

Objective : Since clinical improvement is not associated with a persistent increase in CD4 cell counts, we have evaluated LPR upon ZVD therapy.
Methods : 41 HIV seropositive patients (9 AIDS, 30 ARC and 11 with thrombocytopenia received ZVD with a daily dosage of 1170 ± 240 mg (800 - 1500). Evaluation of LPR was performed before ZVD and after a delay of 116 ± 39 days on therapy. LPR, measured by tritiated thymidine incorporation, were studied in 3-day cultures for pokeweed mitogen (PWM) and in 7-day triplicated cultures for tuberculin (PPD), candidin (CDD), and tetanus toxoid (TT). Results are expressed as Δcpm/0.2 x 10^6 cells ("stimulated" minus "non-stimulated") and as proliferative indexes ("stimulated"/"non-stimulated").

Results	n	Δ cpm before ZVD	Δ cpm upon ZVD	
PWM	25	8 815 ± 10 735	14 355 ± 12 839	$p < 0.05$
PPD	40	14 355 ± 28 338	20 458 ± 44 053	NS
CDD	38	40 066 ± 67 995	38 825 ± 51 453	NS
TET	35	3 705 ± 7 963	7 311 ± 15 902	NS

Among initialy unresponsive patients, some acquired significant LPR (index 3) to PWM = 5/8 and to specific antigens : 8/21 for PPD, 4/7 for CDD and 8/24 for TT. CD4 cell counts were not modified by therapy : 352 ± 338 x 10^6/L (before) to 363 ± 344 x 10^6/l (after).
Conclusion : LPR to PWM increased upon ZVD. Although some patients acquired LPR to specific antigens, mean cpm values were not significantly increased.

C.571

SIGNIFICANCE OF NON-LYMPHOID ACCESSORY CELLS IN ORAL HAIRY LEUKOPLAKIA.

Nicola Pimpinelli, P.Romagnoli, G. Ficarra, L.Borgognoni, R. Riccardi, D.Gaglioti, D. Milo.
University of Florence and U.S.L. 10/D, Florence, Italy.

Objective. To provide further insight into the features of non-lymphoid accessory cells (NLCs), their relationships to lymphocytes, the influence of the epithelial microenvironment on their differentiation and their possible direct viral infection in oral hairy leukoplakia (OHL).
Methods. We studied by immunohistochemistry and electron microscopy (EM) 24 OHL lesions and 5 biopsies from clinically normal mucosa of the lateral margin of the tongue in 2 HIV+ and 3 HIV- control patients.
Results. In the lamina propria, a sparse infiltrate of mainly CD8+ T cells and some CD1a+ dendritic cells was commonly found in OHL lesions and only occasionally in HIV+/- controls. On EM, clusters of lymphocytes and NLCs apposed to each other were found in OHL lesions. In the epithelium, sparse CD8+ cells were common in OHL and occasional in HIV+/- controls. The number od CD1a+ dendritic cells was significantly lower in OHL than in perilesional areas and in controls. NLCs with monocyte-like or indeterminate-like features were found within basal layers. Virus-like particles were seen within these NLCs in 2 cases.
Conclusion. The incomplete differentiation of NLCs and the absence of CD4+ cells in OHL epithelium may be due to the virus-perturbed epithelial microenvironment. The possibility of a direct viral infection of these NLCs is suggested.

C.572

EXPRESSION IN E. COLI, PURIFICATION AND IMMUNOLOGICAL ANALYSIS OF HTLV-1 ENV ANTIGENS.

Tribe, D. E.*, Ganfield, Mong-Ching, Lischwe, M. A., Tritch, R., and Chamberlain, M.**, *University of Melbourne, Melbourne, Australia, E. I. du Pont de Nemours & Co., Medical Products Department, Experimental Station, Wilmington, De, U.S.A., **IBI, New Haven, Ct, U.S.A.

Segments of the HTLV-1 env gene were cloned in E. coli expression vectors. The segments expressed contained both gp46 and p21E determinants.

Good yields of an insoluble env-fusion protein were achieved using a trp expression vector. This insoluble antigen was readily purified from disrupted cells by repeated washings and HPLC reverse phase column chromatography.

Expression of an env segment as an unfused antigen was achieved using a high copy number lambda promoter vector which included translational and transcriptional termination signals downstream of the env insert. Antigen from this system was largely in the soluble fraction.

The immunological reactivity of these antigens was investigated with HTLV-1 specific monoclonal and polyclonal antibodies by immunoblot and ELISA. Analysis of the purified env protein using a limited number of normal, HTLV-1 and HIV-1 positive human sera indicated the env recombinant is reactive with a high percentage of the HTLV-1 positive cera tested.

C.573

LYMPHOCYTE STIMULATION IN ARC/WRS PATIENTS DURING INTRAVENOUS IMMUNOGLOBULIN (IVIG) TREATMENT

H. Krickeberg; Georg Plum; Th.Mertens; G.Mauff; and the ARC-IVIG-Study-Group Cologne/Berne
Departments of Medical Microbiology, Virology, Internal Medicine II, Dermatology, Pathology, Biostatistics, Univ. of Cologne, FRG; Central Laboratory, Swiss Red Cross (Blood Transfusion Service), Berne, Switzerland

Objectives: In a randomized, controlled double blind study 15 ARC/WRS patients were compared during 6 months 0.4g/kg IVIG treatment with 15 placebo treated patients. The project has been described elsewhere (cf.: *Schrappe-Bächer et al.*). Our study was aimed at lymphocyte response to T- and B-cell mitogens.

Methods: ^{3}H-thymidine uptake was determined after stimulation with the unspecific mitogens PHA, PWM, formalinized *S.aureus* - Cowan I (SAC), and with the antigens PPD, and Herpes simplex virus (HSV) at the onset, on day 85 and 183 ; antibodies against HSV were measured by ELISA and CFT. In addition, 30 untreated HIV-negative control individuals were tested.

Results: For T-cell mitogen PHA, T-/B-cell mitogen PWM, and B-cell mitogen SAC no differences between the 2 patient groups were observed at day 1, 85 and 183, but stimulation was significantly lower as compared to the control group (t-test) on day 1. Lymphocytes of 4 patients and 5 HIV-negative control individuals showed PPD response. All patients had IgG-, none IgM-antibodies against HSV (ELISA). In the IVIG-group 8 patients' lymphocytes responded to HSV at some time during treatment, 13 had positive CFT titers; in the placebo group only 3 patients' lymphocytes responded to HSV, 10 had positive CFT titers. Seven HIV-negative individuals showed positive HSV lymphocyte response, 19 with ELISA/CFT titers.

Conclusions: In spite of some clinical improvement regarding fever and fatigue during IVIG treatment, there was no influence on T-/B-cell stimulation by unspecific mitogens. All patients having experienced HSV infections, lymphocyte reactivity to HSV, although statistically not significant, was predominantly seen in the IVIG-patient group.

C.574

"ACTIVE LIPIDS" (AL) IN VITRO: LOSS OF DETECTABLE T- AND B-CELL SURFACE ANTIGEN

Bogner, Johannes R, Matuschke A, Heinrich B, Füeßl HS, Goebel F-D; Universität München, Med Poliklinik, FRG

OBJECTIVE: AL have been shown in vivo to increase the percentage of lymphocytes detectable neither by T- nor B-cell markers ="unstained cells" (UNST) (Stockholm 3531). We have investigated if this effect can also be observed in vitro.
METHOD: Blood from patients with AIDS (n=4) and healthy controls (n=3) was incubated without (1) and with (2) a mixture of lipids similar to AL 721 (triglycerides, phosphatidylcholine, phosphatidyethanolamine) for one hour at 37°C. PBMC were stained with anti-CD3, CD4, CD8, CD19 and HLA DR after and prior to incubation with AL and analysed with two-color flow cytometry.
RESULTS: 2 versus 1 resulted in a significant increase of UNST (mean 4.1-fold ±1.9) and reduction of all other cells (mean 0.67-fold ±0.17). In contrast, 2 did not differ significantly from 1 (UNST 0.97fold ±0.13, other subsets 1.03fold ±0.19) when AL incubation was performed after antibody incubation. difference after/prior $p<0.01$). The effect occurred in all 7 subjects without regard to diagnosis.
CONCLUSION: Our results show that in vitro incubation of lymphocytes with "active lipids" unspecifically lowers detectability of cell surface markers by monoclonals. Physiologic lymphocyte function or virus binding might by altered by AL.

C.575

IMMUNO-ADHERENCE OF *MYCOBACTERIUM AVIUM* (*M.AVIUM*) TO U937 IS ENHANCED BY HIV-1 INFECTION

Bakker, Leendert J; Nottet, HS; Van Strijp, JAG; Visser, MR; Snippe, H; Verhoef, J.
Lab. of Microbiology, State University of Utrecht, Utrecht, the Netherlands.

Objective. To investigate the effect of HIV-1 infection on the function of mononuclear phagocytes. In this study, the interaction of uninfected or HIV-1-infected U_{937} cells with opsonized *M.avium* was compared.
Methods. *M.avium* was directly labeled with FITC, and opsonized with normal human pooled serum (HPS, HIV-negative), or with heat-inactivated HPS. U_{937} and U_{937}/HIV-1 cells were incubated with opsonized *M.avium*, washed and cell fluorescence was measured using flow-cytometry and fluorescence microscopy.
Results. Flow-cytometry showed a 10-fold (10.7±2.5) increase in fluorescence of uninfected U_{937} with HPS-opsonized *M.avium* as compared to non-opsonized *M.avium*. Heat-inactivation of HPS removed this effect. Fluorescence using HPS-opsonized *M.avium* was significantly higher with U_{937}/HIV-1 (1.8±0.4; $p<0.02$) then with uninfected U_{937}, while non-opsonized or heated-HPS-opsonized *M.avium* showed no difference. Microscopy showed that *M.avium* was attached to the cells. Since the increase was complement dependent, complement receptor (CR1 and CR3) expression on U_{937} was measured. Both were significantly higher on U_{937}/HIV-1 (1.8±0.1 and 1.4±0.1 resp.). Inducers of cell-differentiation (PMA, endothelial cell supn.) increased immuno-adherence of opsonized *M.avium* to uninfected U_{937}.
Conclusion. Immuno-adherence of *Mycobacterium avium* to U_{937} is enhanced by HIV-1 infection. This enhancement may be due to upregulation of complement-receptors on U_{937} induced by HIV-1 infection.

C.578

A HUMAN env-LIKE PROTEIN: POSSIBLE RELEVANCE IN HIV INFECTION

Grassi, Fabio; De Santis, C.; Beretta, A.; Gullberg, M.* and Siccardi, A.G.
Dipartimento di Biologia e Genetica per le Scienze Mediche, Università di Milano, Italia, *Unit for Applied Cell and Molecular Biology, University of Umea, Sweden.

Objective. To characterize a human env-like protein.
Results. A 45 kDa human lymphocyte activation-associated protein sharing an epitope with env gp120 has been described and named HELP (human env-like protein). Two monoclonal antibodies reactive with HELP have been produced: one of them (M38) is reactive with both the cellular protein and HIV1 gp120, the other (L31) binds only the human molecule, but its binding can be inhibited by M38, probably because of steric hindrance. The two Mabs have different effects on lymphocyte functions: M38 inhibits proliferation by antigen presentation whereas L31 inhibits IL-2 production by cross-linked OKT3 stimulated lymphocytes. Since HELP acts in negative signalling and an autoimmune response against it induced by HIV infection could be deleterious for the patient, we are now searching for M38- or L31-like specificities in sera from infected individuals to evaluate a possible prognostic significance.
Conclusion. HELP is involved in more than one physiological immune function. Autoimmune responses aganst it are likely to be deleterious to the AIDS patient.

NMR study of perturbations of phosphatidylcholine bilayers by diacylglycerols. H. DeBoeck and R. Zidovetzki. Department of Biology, University of California, Riverside, CA 92521, USA

Addition of diacylglycerols to the cultured HIV-infected cells was recently shown to significantly reduce cytopathological effects of the virus. We used a combination of ^{31}P and ^{2}H nuclear magnetic resonance (NMR) to characterize the perturbations of phosphatidylcholine bilayers by a series of saturated diacylglycerolos (DAG) (diC$_n$ with n=6, 8, 10, 12, 14, 16) and two unsaturated DAGs; diolein and DAG, derived from egg-PC (egg-DAG). Longer chain (n≥12) saturated DAGs induce lateral phase separation of the lipids forming regions with different fluidities. Decreased order of the DPPC side chains was observed in the presence of diC$_6$ and diC$_8$. Addition of diolein or egg-DAG to PC bilayers induces formation of non-bilayer lipid phases. The observed effects can be correlated with the fact that the shorter chain saturated DAGs (up to diC$_8$) and unsaturated DAGs can activate protein kinase C and various phopholipases.

C.582

EFFECT OF NEUROTROPIN ON A SPECIFIC HOST CELL MEMBRANE PROTEIN, HMP-1, INDUCED WITH HIV-INFECTION AND FUNCTIONALY ASSOCIATED WITH SUPPRESSION OF GIANT CELL FORMATION.

Takeoka Yuichi *1,*3; Yashiki S.*1; Maruyama I.*2; Suehiro S. *3 and Sonoda S.*1
*1:Dept. of Virology and *2:3rd Dept. of Internal Medicine Faculty of Medicine, Kagoshima Univ.,Kagoshima, *3:Dept. of Cell Biology & Microbiology, Institute of Bio-ActiveScience, Nippon Zoki Pharmaceutical Co.,Ltd., Hyogo, Japan

The effect of Neurotropin®, a non-protein extract from cutaneous tissue of rabbit inoculated with vaccinia virus and contains biologically active substances formed by immuno-inflammatory reaction, on the formation of giant cell in HIV-infected MT-2 cells was investigated. 10-100 µg/ml of Neurotropin introduced to MT-2 cell culture priorto HIV infection significantly inhibited the giant cell formation. Nonidet P-40 extracts of HIV-infected MT-2 cell membrane proteins were analyzed on 2D gel electrophoresis and the electropholetic pattern of protein species were compared. One of the HIV-induced MT-2 protein designated as HMP-1 changed its pI from 5.8 to 5.6 upon treatement with Neurotropin. This change was not due to phosphorylation of HMP-1. It seems that HMP-1 is a fusion-associated molecule and specifically influenced by Neurotropin, thereby suppressing the formation of giant cells.

C.583

NITROPHENYL DERIVATIVES (NP) AS POTENTIAL ANTI-HUMAN IMMUNODEFICIENCY VIRUS (HIV) AGENTS
Matsiota, P.*; Guétard, Denise** et al.
*Immunocytochimie; **Oncologie Virale, Institut Pasteur, Paris, France.

Objective. To assess the *in vitro* anti-HIV activity of NP derivatives.
Methods & Results. We report that nitrophenyl derivatives (NP) (dinitrophenyl-glycine, trinitrophenyl-bovine serum albumine) neutralize HIV as assessed by reverse transcriptase activity determination in culture supernatants of peripheral blood monocytes and syncytia formation assay. FACS analysis demonstrated that NP derivatives although they interfered with viral fixation did not compete for the receptor recognized by monoclonal anti-T4 antibodies. Apparently, this in vitro antiviral effect is specific because it is abolished after passage of the NP compounds through immunoadsorbents carrying a monoclonal anti-NP antibody and it is recovered in the acid eluate of the immunoadsorbents.
Conclusion. These results suggest that NP derivatives may interfere with HIV fixation. Whatever the exact mechanism of action is, the antiviral effect of NP derivatives seems to be related to their anionic charges, since reduced NP derivatives lose their anti-HIV activity.

C.584

TREATMENT OF MAJOR DEPRESSION, NEW ONSET, IN PATIENTS WITH HIV POSITIVE SEROLOGY WITHOUT ACTIVE DISEASE WITH FLUOXETINE
Levine, Stuart H. University of California, U.S.A.

Seven patients were referred from the UCLA AIDS Research Center who met criteria for DSMIII-R Major Depression. All of these patients were participating in an AZT double-blind placebo-controlled study at the Center. Five of the patients had positive HIV serology but no manifestations of the disease; the remaining two patients had positive HIV serology and had one symptom of Early ARC in the past but were no longer actively symptomatic. None of the patients have had previous significant psychopathology before their HIV serologic diagnosis. All seven patients were treated with fluoxetine at 20 mg. per day. All patients tolerated fluoxetine without any long term side effects. (GI upset, increased bowel movements, and sleep disturbances abated after one week at full dose). All patients responded to fluoxetine after one month of administration at 20 mg. per day. Average Hamilton Depression Scales were initially, 26 (range 20-33), 7 (range 2011) after one month, and 2 (range 0-5) after three months of fluoxetine administration. In conclusion, our experience suggests that fluoxetine is an efficacious anti-depressant is well-tolerated in patients with Major Depression and with HIV positive serology patients without active disease.

C.585

CHARACTERIZATION OF TANNINS CONTAINING ANTI-HIV ACTIVITY.

Kilkuskie, Robert E.*; Cheng, Y.-C.**; Lee, K.-H.** and Bodner, A.J.*
*Biotech Research Laboratories, Inc., Rockville, MD 20850, USA.
**University of North Carolina, Chapel Hill, NC 27599, USA.

Objective. To characterize anti-HIV activity of purified tannins. Methods. Tannins were purified from commercial tannic acid by chromatography through Sephadex LH-20 and preparative high performance liquid chromatography with reverse phase columns. HIV-1 reverse transcriptase was purified by immunoaffinity chromatography. Enzyme activity was measured using poly rA-oligo dT_{10} as the template. HIV-1 replication was assayed after infection of H9 lymphocytes. A p24 antigen capture test was used to detect virions released into culture supernatants after a three day incubation following HIV-1 infection. Drug cytotoxicity was evaluated by cell count after a three day incubation with uninfected H9 cells. Results. Four new tetragalloylquinic acids were isolated which inhibit purified reverse transcriptase by 85-90% at 100 uM and 60-70% at 30 uM. They inhibit HIV-1 replication in H9 lymphocytes by at least 50% at 1-6 uM without cytotoxicity to uninfected H9 cells. Drugs were cytotoxic (approximately 50% growth inhibition) at 25-60 uM. Inhibition of HIV-1 replication in H9 cells by tetragalloylquinic acid was assayed in the presence of either AZT or ddC. Inhibition by the combination of drugs was additive at all concentrations of AZT or ddC tested. Conclusion. A new class of plant products which inhibit purified reverse transcriptase and HIV-1 replication in vitro has been isolated and characterized.

C.586

TREATMENT OF AIDS ASSOCIATED CRYPTOSPORIDIOSIS WITH HYPER-IMMUNE COLOSTRUM FROM COWS VACCINATED WITH CRYPTOSPORIDIUM.

J. Nord, P. Ma, C.O. Tacket, D. Dijohn, S. Tzipori, D. Sahner, G. Shieb. St. Vincent's Hosp. & Med. Ctr. of New York, Univ.of Maryland, Dept. of Medicine, Royal Children's Hosp. Melbourne, Australia.

Objective. To assess the efficacy of hyperimmune bovine colostrum against Cryptosporidium in symptomatic AIDS patients.

Methods. Bovine colostrum was obtained from cows hyperimmunized with Cryptosporidium antigens. 5 AIDS patients with diarrhea and Cryptosporidiosis were given the colostrum by continous infusion via feeding tube in a double blind, placebo controlled pilot study. Stool was analyzed for vol.,frequency & consistency. Quant. cryptosporidial oocyst counts were determined by mod.Cold Kinyoun stained smears. Antibody titer of colostrum was assayed by IFA.

Results.

Patient	Antibody Titer of Colostrum	Conc. of Oocysts/ml 1st day	Conc. of Oocysts/ml Last day	Diarrheal Symptoms
A	1:25,600	1.4×10^7	2.2×10^6	Improved (2 mos.)
B	1:3200	8.4×10^4	2.0×10^3	Resolved (6 mos.)
E	1:3200	1.6×10^6	1.8×10^6	No change
C	Placebo	2.0×10^7	6.0×10^6	No change
F	Placebo	1.9×10^6	4.0×10^6	No change

Conclusion. Placebo showed no effect on the diarrhea. Two of three patients receiving hyperimmune colostrum showed clinical improvement/resolution accompanied by a reduction of oocysts in the stool. One patient receiving the hyperimmune colostrum failed to respond. A combination of low antibody titer and high oocyst concentration may be responsible. Therefore, higher antibody titers may be required for treatment of high oocyst concentration.

C.587

THE EFFECT OF OZONE(O3) ON LYMPHOCYTE POPULATIONS IN NORMAL AND HIV1-INFECTED BLOOD.

Wagner, Kenneth*; Mayers,D.**; Toro,L.***; Baker,J.R.Jr. ***. *Henry M Jackson Foundation, Rockville, MD., **National Naval Medical Center, Bethesda, MD. ***Walter Reed Army Medical Center, Washington, DC., U.S.A.

Objective. Measure the effect of varying O3 concentrations on lymphocytes in whole blood from an uninfected and a Walter Reed Stage 2 HIV1 patient. Methods. Heparinized whole blood samples were exposed in triplicate to [O3] of 20, 40 and 60 ug/ml with an oxygen control. Coded, blinded blood samples were gently agitated for 10 min. and incubated for 1 hr. at 27 C. Mononuclear cells were separated using Ficoll-hypaque gradients and stained for FACS analysis using labelled monoclonal antibodies. Results. O3 had no effect on lymphocyte populations of the uninfected donor as numbers of total T cells, CD4, CD8, and B cell subpopulations did not change. In contrast, there were marked changes in the lymphocyte populations of the HIV positive donor with increasing [O3]:

$[O_3]$ (ug/ml)	B cells %CD20	T cells %CD3	CD4* %	CD8* %	T4/T8*	DR positive* % T cells	IL2 receptor* %CD25
0	8.5	82	34	43	.01	12.3	1.0
20	8.6	79	34	41	.05	14.9	0.0
40	8.4	82	40	38	1.10	10.3	0.5
60	6.9	83	42	36	1.20	7.0	0.2

* Correlation with increasing O3 concentration ($p < .05$)

Conclusions. Ozone, at concentrations previously shown to inactivate HIV1, may alter lymphocyte surface markers in HIV1 infected patients. Further studies are indicated to examine this effect.

C.588

DEC AND PER CAPITA AIDS CASES

Kitchen, Lynn, Tulane University Medical Center, New Orleans, LA, U.S.A.

Objective: Administration of the antifilarial/immunomodulator drug diethylcarbamazine (DEC) frequently alters virologic, hematologic, serologic, and clinical parameters in cats infected with feline leukemia virus--an animal model for AIDS. DEC is an orally bioavailable drug, and some experiments suggest that DEC is concentrated in brain tissue. The present study examines, on a country-by-country basis, the relationship between filariasis control programs involving administration of DEC and per capita reported AIDS cases.

Methods: Numbers of known AIDS cases (WHO 2/88) in each of 161 countries/geographic entities were combined with population data to obtain per capita figures for known AIDS cases. The countries were divided into 3 subgroups according to DEC status: Group 0, no evidence of filariasis (52 countries); Group 1, DEC use sporadic or unknown to author (97 countries); and Group 2, program initiated to administer DEC to carriers of filariasis or to larger proportion of population on a national scale subsequent to development of DEC as an antifilarial agent (12 countries). The null hypothesis that DEC has no effect on numbers of per capita AIDS cases was tested by the 1-sided rank-sum test against the alternative hypothesis that use of DEC is associated with fewer per capita cases.

Results: The null hypothesis was rejected (a) when group 2 countries were compared against the remaining 149 countries ($p<.003$), and (b) when group 2 countries were compared against the 52 countries in group 0 ($p<.0005$).

Conclusion: These preliminary observations suggest that the effect of DEC on HIV infection warrants additional study.

C.589

C.590

WOMEN UNDERREPRESENTED IN AIDS CLINICAL TRIALS

Long, Iris; Kirschenbaum, D.; McCarthy, M. AIDS Coalition to Unleash Power, New York, New York, USA.

Objective. To monitor the access of women to experimental AIDS treatments in the United States. Method. We collected data on women enrolled in U.S. Government ACTG clinical trials to identify hindrances to health care. Results. Current Food and Drug Administration (FDA) policy restricts access of all patients to experimental therapies for AIDS on the theory that easy access to drugs will prevent patients from entering trials. Yet historically, women have been prohibited from participating in clinical trials. Even AZT, the one anti-HIV drug approved in the U.S., has not been adequataly tested in women to show beneficial as well as adverse reactions as required by the FDA. Although in November 1988 women represented 9% of CDC-defined AIDS cases, women at all stages of disease comprised only 5.8% of total trial enrollment. In February 1987, 142 women were enrolled in ACTG trials; by August 1988, 200 women were enrolled. Over 60% of women in ACTG trials are enrolled in ACTG trial 019 which is testing AZT versus placebo in asymptomatic HIV-infected subjects. As of December 1988, 52% of women with AIDS in the U.S. were infected through IV drug use. Nationally, 70% of women with AIDS are black and hispanic. Most of these women are poor and have access only to public hospitals. Conclusions. Government and medical establishment policies restrict the access of women to experimental treatments. These results imply inadequate drug approval policies, poor health care on the local level, and many unsolved bioethical issues.

C.591

IN VITRO EVALUATION OF EFFECTS OF LF1695 ON HIV INFECTED CELLS, ALONE OR IN ASSOCIATION WITH ANTIVIRALS.

Dubeaux, Dominique(1); Delestre, L.(1); Clayette, P.(1), Abita, J.P. (2), Lizard, G. (2); and Dormont, D.(1,3).
(1) Centre de Recherches du Service de Santé des Armées, Commissariat à l'Energie Atomique, Fontenay-Aux-Roses, France. (2) Laboratoires Fournier, Dijon, France. (3) Institut Pasteur, Paris, France.

Objective : To determine the cellular target of an immune modulator drug, LF1695, in HIV infected PBL and infected cell lines, and to evaluate potential interactions with antivirals.
Methods : Interactions of LF1695 with lymphocyte membrane have been studied by Spin Label Method and competition assays between monoclonal anti CD4 antibodies and LF1695 (Immunofluorescence). Dose response curves of LF1695 action on HIV Reverse Transcriptase activity have been established (poly rA-oligo dT). In vitro toxicity of the drug on normal human PBL has been determined. Effects of LF1695 on cell growth and HIV replication has been explored using RT assay on cell culture supernatants. Potential interactions between LF1695 and antivirals (AZT, ddC) have been assayed by measurement of RT activity in supernatants of cell cultures which where doubled treated with both drugs at different concentrations.
Results : Biophysical effects of LF1695, such major interactions with the external part of cell membrane has been demonstrated, and might explain both the antiviral effect observed in few HIV infected PBL cultures, and the competition with antiLeu3a antibodies noted in around 10 per cent of healthy donors. No direct anti reverse transcriptase effects could be demonstrated for LF1695. Immune modulating concentrations of LF1695 do not exhibit either cellular toxicity or reproductible antiviral effects, as demonstrated in IL2 stimulated HIV infected PBL cultures. However, some inhibition of HIV replication was noted in a cell line of monocyte origin,U937. LF1695 does not interact with antiviral effect of dideoxynucleotides : furthermore, it allows a normal cell growth in cell cultures treated with a 100 per cent antiviral dose of AZT.
Conclusion : LF1695 is an immune modulator drug which cellular target is the cell membrane : despite the lack of direct antiviral effect, this drug might be used in association with dideoxynucleotides, as a compensator of the antiviral cellular toxicity.

C.592

INHIBITION OF HIV-1 AND HIV-2 REPLICATION IN FRESH AND CHRONICALLY INFECTED CELLS WITH ANTIVIRAL AGENTS

Sun, Daisy K.L.*; Pontani, D.**; Thornton, A.H.*; Fullen, J.*; Shahied, S.I.** and Sarin, P.S.*
*Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Maryland. **New Jersey State Department of Health, Trenton, New Jersey. U.S.A.

We have examined and compared the inhibition of HIV-1 and HIV-2 replication in fresh and chronically infected cell cultures by a number of drugs directed towards various stages in the virus life cycle. We have evaluated the effect of these drugs, including AZT, DDC, foscarnet, amphotericin methyl ester (AME) on HIV-1 and HIV-2 replication in freshly infected and chronically infected Molt-3 and H9 cells. It appears that some drugs can inhibit both HIV-1 and HIV-2 replication at similar drug concentrations, whereas others require a higher drug concentration to inhibit HIV-2. Similar differences were observed between the potency of these drugs on freshly infected cells as compared to chronically infected cells. These studies indicate that it may be extremely important to select antiviral agents which are equally active on both freshly infected and chronically infected cells for the treatment of AIDS.

C.593

BIOCHEMICAL PHARMACOLOGY OF AZT IN HUMAN T-LYMPHOBLASTOID CELLS (CEM).

Vassilios I. Avramis, Wendy Markson, Edward Gomperts & John S. Holcenberg. Childrens Hospital of Los Angeles, Los Angeles, CA, U.S.A.

The purpose of this study was to investigate the biochemical pharmacology of AZT and to examine the effect of AZT on nucleotide triphosphate pools in virus-free human T-origin line (CEM) cultured in vitro. Although the inhibitory concentration 50% (IC_{50}) of AZT in this cell line averaged 3.90 ±2.9µM (n=5 determinations ± S.Dev.), the readily obtained plasma concentration of AZT in patients (1 µM) was used in these studies. CEM cells were incubated with 1µM of [^{3}H]AZT for 24 hrs in vitro and at various times triplicate aliquots of 10^7 cells were removed and extracted with perchloric acid for nucleotides and metabolites of AZT. The extracts were assayed by HPLC SAX-10 column for nucleoside, mono-, di-, and tri-phosphate anabolites of [^{3}H]AZT. The cellular concentration of AZT ranged from 0.98 to 1.8µM (mean 1.28 ±0.3µM) throughout the 24 hr experiment. The [^{3}H]AZTMP cellular concentrations exceeded 1.3µM at 2 hrs and declined gradually to 0.12µM by 18 hrs. The [^{3}H]AZTDP was on average 17.5 ±11.4 fold lower than the AZTMP, strongly indicating that a rate-limiting step in the activation of AZTMP to AZTDP exists at the dTMP kinase level. The triphosphate, [^{3}H]AZTTP, peaked 4 hrs after initiation of drug treatment at 14.5 nM in CEM cells and declined biexponentially with a $t½_{\alpha}$ of 5.2 hrs and a $t½_{\beta}$ of 10.1 hrs. NTP cellular concentrations declined rapidly in the cells after exposure to AZT and by 9 hrs reached a nadir of 21.2% CTP, 8.1% UTP, 13.2% ATP and 14.4% GTP, in comparison to control values. Consequently, phosphorylation of AZT to AZTMP and AZTMP to AZTDP declined 2.9- and 2.4-fold, respectively. The depletion of NTP pools may be responsible for the host toxicity that has been observed in patients. The amount of AZT anabolite incorporated into purified DNA peaked at 0.066 pmoles/10^7 cell DNA 1 hr after AZT treatment and declined with a t½ of 12 hr. We conclude that 1µM AZT is sufficient for activation to the triphosphate which is associated with depletion of NTP pools and is incorporated into DNA.

C.594

C.595

DIFFERENTIAL ANTIRETROVIRAL ACTIVITY OF DEXTRAN SULFATE, PENTOSAN POLYSULFATE AND HEPARIN AGAINST HIV-1 (HTLV-III_B) AND HIV-2 (LAV-2 ROD) in MT-4 CELLS

Rudi Pauwels, M. Baba, D. Schols, J. Balzarini, J. Desmyter, and E. De Clercq.
Rega Institute for Medical Research, K.U.Leuven, B-3000 Leuven, Belgium.

Objective. Since sulfated polysaccharides interfere with the interaction of the highly variable envelope glycoproteins of HIV with the cellular CD4 receptor, we wondered whether these compounds may have differential effects on different HIV-1 and HIV-2 strains.
Methods. Anti-HIV activity was determined 5 days post-infection by a tetrazolium-based viability assay. All HIV strains were used at the same multiplicity of infection and all experiments were done in MT-4 cells.
Results.

	50 % Effective dose [µg/ml, except for AZT (µM)]			
	AZT	Dextran sulfate	Pentosan polysulfate	Heparin
HIV-1(III_B)	0.0013	0.7	0.3	0.7
HIV-2(ROD)	0.0013	0.03	0.005	28
Ratio	1:1	23:1	60:1	1:40

Conclusion. Whereas AZT was equally effective against both HIV-1 and HIV-2, dextran sulfate and pentosan polysulfate were significantly more inhibitory to HIV-2 than HIV-1. Heparin, however, was more inhibitory to HIV-1 than HIV-2. These findings point to a specific interaction of sulfated polysaccharides with the HIV envelope glycoproteins. As pentosan polysulfate and dextran sulfate could be detected in the ng/ml range by using HIV-2(ROD) as the challenge virus, the HIV-2(ROD)/MT-4 system could be used as a bioassay for the detection of these compounds in biological specimens.

C.596

GLQ223: AN INHIBITOR OF HIV REPLICATION IN ACUTELY AND CHRONICALLY INFECTED T CELLS AND MACROPHAGES

McGrath, MS*; Hwang, KM**; Caldwell, SE**; Gaston, I*; Lak, K-C**; Lifson, JD**; et al.
*San Francisco General Hospital, San Francisco, California, USA, **Genelabs Incorporated, Redwood City, California, USA

OBJECTIVE. To evaluate GLQ223 for ability to inhibit HIV replication in acutely and chronically infected cells and cells of both lymphocyte and mononuclear phagocyte lineage.

METHODS. GLQ223 is a highly purified plant derived protein used, in crude form, in traditional herbal medicine for a variety of clinical indications. GLQ223 was tested for ability to inhibit HIV replication in assay systems employing target cells of both lymphocyte and mononuclear phagocyte lineage, in acute and chronic infection models. Viral replication in treated cultures infected with laboratory isolates of HIV was assessed, as were effects of GLQ223 on cultured cells from HIV-infected donors. Viral replication was monitored by flow cytographic immunofluorescence analysis, antigen capture immunoassay of culture supernatants, and northern blot analysis.

RESULTS. GLQ223 showed concentration dependent inhibition of HIV replication in acute infectivity assays using a CD4+ T cell line as target. Complete inhibition of viral replication was obtained at concentrations of GLQ223 which were not toxic to parallel cultures of uninfected cells. Northern blot analysis showed a selective proportional decrease in the amount of viral RNA compared to levels of a representative cellular RNA species in treated cultures. Treatment of chronically HIV-infected monocyte/macrophage cultures also showed selective inhibition of HIV antigen expression. A single 3 hour exposure of whole blood from HIV-infected patients to GLQ223 was sufficient to prevent the expression of HIV antigens which occurred upon subsequent culture when the cells were not treated.

CONCLUSION. GLQ223 is a compound with encouraging in vitro anti-HIV activity in both acute and chronic infection, in both T cells and monocyte/macrophages. The mechanism of action is under investigation.

IN VITRO INHIBITION OF HIV REPLICATION BY CHOLIC ACID

M Theodoropoulou1, P Cornuet 2, A Gravanis 1, C Stournaras 1
Psychoyos 3, C Jasmin 2, V Georgoulias 1
1 School of Medicine, University of Crete, Greece 2 INSERM U268, Hop Paul
Brousse, 94804 Villejuit, France 3 Hopital Kremlin-Bicetre, 94000, France

Objective: To determine whether the physiological constituent of the non-receptive endometrium cholic acid (CA) which is displaying both ovotoxic and spermatoxic activity, could also inhibit HIV replication

Methods: Different concentrations of CA were incubated with either the HIV reverse trancriptase (RT) enzyme or with an infectious viral preparation which used subsequent for infection of permissive cells. The effect of the agent was determined by measuring the enzymatic activity as well as the RT activity and p24 antigen in the supernatant of infected cultures, respectively.

Results Dose response curves showed that CA was capable to inhibit in a dose-dependant manner the RT activity of HIV. Moreover, CA also inhibited the DNA polymerases. RT inhibition was 99% at 40 mM CA concentration. When HIV virions were incubated with CA before testing the RT activity, an increase of the enzymatic activity was observed at low concentrations (2.5 mM) which was completely inhibited at higher concentrations (25 mM), suggesting a detergent-like effect of the agent. This effect was further supported by the decreased cell viability induced by CA. Incubation of infectious viral prepatations with CA for 10 min, extensive washing and cell infection, resulted in about 80% decrease of the infectivity capacity of HIV at 25 mM of CA as determined by the RT activity and p24 Ag in the culture supernatant

Conclusions: The above results indicate that CA has a relatively potent anti-HIV effect which is due to both the detergent-like and the anti-polymerase effects of CA. Since CA is a physiological constituent of the organism with little toxic effects, this agent could be used to develop protective measures against HIV infection

C.598

SUPPRESSION OF HIV RESERVOIR CELLS BY MEMBRANE-ACTIVE SUBSTANCES

Willer, Andreas*, Buff, K.**, Mellert, W.*, Goebel, F.-D.***, Erfle, V.*
*GSF-Abteilung für Molekulare Zellpathologie, 8042 Neuherberg/München,
**GSF-Institut für Zellchemie, 8042 Neuherberg/München, FRG;
***Medizinische Poliklinik der Universität, 8000 München, FRG.

Objective: HIV can productively infect several cell types such as monocytes/macrophages and lymphocytes *in vivo* without subsequent cytolysis, thus creating a "virus reservoir". Strategies to suppress or to eliminate virus reservoir cells have been designed using the HIV-induced membrane alterations.

Methods: The influence of Phosphatidylcholine (PC) and related substances on viability and growth of HIV-1-infected lymphoid cells and the effects of PC on HIV-2-infected macrophages were investigated.

Results: Incubation of HIV-1-infected lymphoid cells with PC and related substances resulted in selective growth inhibition and lysis of the infected cells and in suppression of viral spread in HIV-2-infected macrophages. These substances had no direct effect on the virus itself and did not interfere with the infection of new target cells.

Conclusions: PC and related substances have the potential to suppress and to eliminate HIV-infected cells and may thus be of therapeutic value to control the virus reservoir early in infected persons.

COMMUNITY-BASED RESEARCH IN AIDS: CRI AS MODEL

Thomas Hannan, NY Community Research Initiative, New York, NY,
U.S.A.

OBJECTIVE. To demonstrate how community-based research can represent a successful alternative model for the design and conduct of clinical research in AIDS, expanding the number of study participants and increasing compliance (especially including minorities and groups normally underrepresented in trials), employing community physicians and incorporating the perspective of people with AIDS in the process.

METHOD. The CRI is registered and approved by the New York State Department of Health to sponsor well-designed, meaningful, clinical trials of promising AIDS/ARC treatments conducted in a community setting by qualified physicians in cooperation with informed volunteer subjects recruited from their practices. The CRI has its own Board of Directors, an impressive Institutional Review Board (IRB) and a Scientific Advisory Committee composed of scientists and clinicians thoroughly experienced in the field of AIDS.

RESULTS. Although the CRI has been in existence for little more than one year, it already has 5 IRB-approved clinical trials fully enrolled and underway, as well as 4 other important formal studies about to begin. In addition, the CRI has an informal monitoring project of antabuse, the results of which were presented at the IVth International Conference on AIDS in Stockholm. The CRI has also generated a report submitted for publication on the endocrine abnormalities in AIDS of low DHEA levels. Both reports represent evidence of CRI's ability to collect and present meaningful data quickly.

We are prepared to present the procedures for development of research projects from potential sources, approval process and actual conduct of trials, emphasizing practical aspects and concerns unique to community-based research conducted in an AIDS context.

C.602

DHEA AND DHEAS IN AIDS

Sonnabend, Joseph*; Fleischer, T.*; and Seeman, J.D.*
*Community Research Initiative, New York, NY, U.S.A.

Objective. To describe results of a study of dehydroepiandrosterone (DHEA) and DHEA-sulfate (DHEAS) in people with AIDS (PWAs).

Methods. Blood samples were drawn between 2:00 and 5:00 PM from 17 PWAs; they were submitted to a commercial laboratory for radioassay-determinations of DHEA and DHEAS levels as well as for determination of other blood parameters. Results were corrected for age and compared to normal values. Other variables potentially affecting DHEA and DHEAS levels were evaluated.

Results. DHEA and DHEAS levels were significantly lowered in PWAs as compared to healthy, age-matched controls. The statistically significant (p 0.01) difference was not attributable to other variables such as concomitant medication, length of time since diagnosis, initial AIDS-defining diagnosis, etc. Decreased levels of DHEA and DHEAS were not correlated with number of CD4+ helper cells or with levels of other blood parameters.

Conclusion. Our results suggest a relationship between AIDS and steroid metabolism, though our data provide no information on the nature or direction of that relationship. Nevertheless, they provide a preliminary rationale for the current practice of attempting to elevate DHEA and DHEAS levels by exogenous administration of DHEA as replacement therapy. Further, these results suggest that structural adrenal abnormalities, so commonly found on postmortem examination of PWAs, though not paralleled in vivo by functional abnormalities as assessed by usual measures of adrenal function, are paralleled by another, perhaps more sensitive index of that function: DHEA and DHEAS levels.

C.603

MM-1 IN THE TREATMENT OF AIDS. REPORT ON 172 TREATED PATIENTS.

Shafik, Ahmed*; Lurhuma, Z.**; Diese, M.***; Wayne, J.****.
* Cairo University, Cairo, Egypt:
, *, **** University of Kinshasa, Kinshasa, Zaire.

The result of treatment of 172 AIDS patients with MM-1, an antiviral drug, is presented. Twenty AIDS patients were treated with the standard treatment for opportunistic infections and were considered as controls.
Patients were monitored for clinical and laboratory changes before, during and after treatment. MM-1 was given in a dose of 0.07 ml/kg body weight, one injection every other day for 10 injections, and every third day for another 10 injections.
Of the 172 patients treated with MM-1, 24 died: 6 of cryptococcal meningitis, 8 of electrolyte imbalance from diarrhea, and 10 of Kaposi's sarcoma. Improvement achieved in 148 patients. Follow-up varied from 4 to 14 months. MM-1 showed no side effects except fever after each of the first 3 injections. The patients showed clinical improvement and immunologic restoration to normal. The 20 control patients died within the follow-up period.

C.605

C.606

INHIBITION OF EXPRESSION OF NATURAL UAC SUPPRESSOR GLUTAMINE tRNA IN HIV- AND MOLONEY VIRUS-INFECTED HUMAN H9 CELLS IN VITRO BY AVAROL

Müller, Werner E.G.*; Kuchino, Y.**; Schröder, H.C.*
*Institut für Physiologische Chemie, Universität, Duesbergweg, 6500 Mainz, West Germany, ** Biophysics Division, National Cancer Center Research Institute, Chuo-ku, Tokyo 104, Japan.

Objective. To study the mode of action of the anti-HIV compound Avarol. Methods. Human T cells (H9), infected with HIV-1 and NIH-3T3 cells, infected with Moloney Murine Leukemia Virus (Mo-MuLV) have been used for the studies. Results. Avarol is a sesquiterpenoid hydroquinone, which causes a strong antiviral effect on HIV and Mo-MuLV in vitro. It was found that in HIV- or Mo-MuLV-infected cells a high level of the UAG suppressor glutamine tRNA-UmUG is present. In Mo-MuLV-infected cells this tRNA is required for the synthesis of the RNA, coding for the viral protease; the function of this tRNA in HIV-infected cells is not yet known. Avarol causes at virostatic concentrations a reduction of the virus-induced UAG suppressor tRNA to normal levels. The functional consequence of this event is an inhibition of the processing of the viral polyproteins, very likely due to an inhibition of the readthrough of the Mo-MuLV protease gene; in the HIV system the molecular explanation is not yet possible. Conclusion. This study demonstrates that an inhibition of HIV production can be achieved also by a selective inhibition of the expression of a cellular gene. Refs.: Müller et al., AIDS Res. Human Retrov. 4, 279 (1988); Kuchino et al., Virology 165, 518 (1988). Supported by grants from the Bundesgesundheitsamt.

C.607

INHIBITION OF HIV REPLICATION BY XYLAN-POLYHYDROGENSULFATE: HOE/BAY 946, A NEW ANTIVIRAL COMPOUND IN CLINICAL TRIAL.

Lothar Biesert*, H. Suhartono*, I. Winkler**, E. Schrinner**, H.-D. Schlumberger ***, H. Rübsamen-Waigmann*.
*Chemotherapeutisches Forschungsinstitut Georg-Speyer-Haus, Frankfurt, FRG, **Hoechst AG, Frankfurt, FRG, ***Bayer AG, Wuppertal, FRG.

Objective. HOE/BAY 946, a xylenpoly-(hydrogensulfate) disodium salt, inhibited HIV-1 and HIV-2 replication and virus-induced cell fusion in lymphocyte cultures at concentrations above 25 μg/ml (4.2 μmol/l) totally. The drug was found to be an inhibitor of the HIV-enzyme reverse transcriptase. Experiments were performed to find out which step of the virus life cycle was inhibited by the drug in the living cell.
Methods. HIV-infection of lymphocytes was detected by determination of syncytia formation, reverse transcriptase activity and antigen release.
Results. 1) An inactivating effect of the compound for free virions could not be demonstrated. 2) Lymphocytes incubated with HIV in the presence of 100 ug/ml HOE/BAY 946 followed by the removal of both the drug and unbound virus were found to be infected. Thus, inhibition of virus adhesion to the cells may not be sufficient to avoid their infection. 3) Several experiments showed that the permanent presence of the drug was necessary for its full antiviral activity. 4) Treatment of a permanently HIV-infected monocytic cell line resulted in a drastic reduction of virus shedding and points to an additional mode of action. It is discussed that HOE/BAY 946 has an influence on virus assembly or virus release.
Conclusion. Based on the anti-HIV activity of the compound, a clinical pilot study with HOE/BAY 946 was started recently in Germany with AIDS-patients and asymptomatic virus carriers.

C.608

Hypericin mediates Anti-HIV Effects in Vitro:

D. B. Weiner[1,2], G. Lavie[3], W., V., Williams[2], D. Lavie[4], M.I. Greene[1], D. Mueralo[3]: Department of Pathology[1], Department of Medicine[2], University of Pennsylvania, Philadelphia PA, 19104-6082., Department of Pathology and Kaplan Cancer Center[3], New York University Medical Center, 550 1st Avenue, New York, NY 10016, The Weizmann Institute of Science, Rehovot 76100, Israel.

Objective: To examine the ability of two aromatic polycyclic diones hypericin and pseudohypericin to control HIV infection in vitro. Methods: Evaluation of syncytia formation, reverse transcriptase activity, Viral RNA production, biochemical as well as electron micrographic studies of HIV-1 and HIV-2 have been studied. Conclusion: The low in vitro and in vivo toxicity of these compounds, the ability to interfere with infectious virus particle production, the fact that humans have been treated with these compounds with no serious side effects as well as the widespread availibility of these agents, suggest further examination of hypericin for future AIDS patient therapeutic regeims may be warranted. Results: Both HIV-1 and HIV-2 were sensitive to the effects of hypericin. Hypericin posesses at least two different antiviral components antisyncytia and blocking of viral infectivity. Morphological examination demonstrates a significant difference in the number of virus particles exhibiting the mature HIV-1 virus phenotype after hypericin treatment. Hypericine does not have direct effects on several commercially available viral reverse transcriptases. Viral maturation appears sensitive to the presence of this compound at doses that manifest no anti-cellular activities. Studies in our laboratory have demonstrated synergistic anti-viral effects between this class of compounds and other inhibitors of HIV infectivity. Further examination of the mechanism of anti-viral effects of these compounds is in progress.

C.609

EVALUATION OF erythro-9 (2-hydroxy-3-nonyl) adenine (EHNA) TREATMENT ON HIV-1 REPLICATION

Yoshitatsu Sei*, I. Tsuboi**, M.M. Yokoyama **, and Prince K. Arora *
* Laboratory of Neuroscience, NIDDK, National Institutes of Health, Bethesda, MD, U.S.A.
** Department of Immunology, Kurume University School of Medicine, Japan.

Objective. To evaluate the efficacy of EHNA treatment on viral replication in HIV-1 infected cell lines *in vitro*.
Methods. HIV-1 infected or uninfected H9 cell lines were treated with varying concentrations of erythro-9(2-hydroxy-3-nonyl) adenine(EHNA), an inhibitor of the common Adenosine deaminase(ADA) isozyme(s)(ADA1 and ADA1+CP). Several different concentrations of deoxycytidine (dC) were also added to the cell cultures. Cell viability was assessed by vital dye exclusion. Reverse transcriptase (RT) activity in the supernatants and in the cell lysates was determined by standard RT activity assays.
Results. RT activity in the supernatant was inhibited by nearly 50% in EHNA-treated HIV-1 infected H9 cells, when compared with the untreated but infected H9 cells. There was also a significant decrease in cell viability, but this was reversed following the addition of dC to these cultures. This combined treatment had no effect on RT activity in the cell lysates, suggesting an inhibition of HIV-1 replication, and release from the infected cultures. This combined treatment was also effective in suppressing HIV-1 release of HIV-1 from infected U937 cells.
Conclusions. The combined treatment with EHNA+dC may be one means of suppressing viral replication in HIV-1 infected cells. Also, since EHNA inhibits adenosine deaminase, HIV-1 release from infected cells may be regulated by purine metabolic pathways.

C.610

CONTROLLED EVALUATION OF THE EFFECT OF ZIDOVUDINE ON NEUROPSYCHOLOGICAL TEST PERFORMANCE IN CDC GROUP IV HIV INFECTED INDIVIDUALS

[illegible], A.E., Vearnals, S., Church, J., Helbert, M., Peters, B., Pinching, A.
Psychology Department and Immunology Dept., St. Mary's Hospital, London, W2 1NY, U.K.

Objectives: To evaluate the effectiveness of Zidovudine in reversing cognitive impairment in CDC Group IV HIV infected patients and to judge the speed of drug effectiveness.

Method: Monthly evaluation on a battery of neuropsychological tests was carried out on Zidovudine treated patients (N=20) and control groups: (1) HIV infected ARC patients treated for non-current syphilis (N=15) (2) CDC Group IV patients treated with AL721 (N=10) (3) HIV seronegatives. Tests used included (CANTAB), Trail-Making, Work Fluency, Rey Auditory Verbal Learning and St. Mary's Computerised Dual Attention task. Multivariate analysis of variance was used to look at changes over testing sessions for each of the groups.

Results: On an overall impairment score calculated by summing standardised (zscores) over the individual tests there was a significant ($p<.03$) interaction between group and improvement on testing. This was mainly due to greater initial improvements in the Zidovudine treated group as compared to the other groups. They did not however continue to improve in all cases. Further follow-up is continuing.

Conclusion: Zidovudine does appear to improve overall neuropsychological test performance in those with AIDS. Where improvement is seen it is likely to be greatest in the first few months of treatment.

C.611

C.612

ANTI-HIV-1 ACTIVITIES OF SULFATED MONOSACCHARIDES (SMS) AND POLYSACCHARIDES (SPS): THERAPEUTIC INDICIES (TI)

Bagasra, Omar ; Lischner,H.W. ;Halligan, G.E. ;Heine, B*.
*Univ. of Medicine and Dentistry of New Jersey, Camden, NJ, Temple Univ. Sch. of Med. and St. Christopher's Hosp. for Children, Philadelphia, PA USA.

Objective. To compare the TI *in vitro* of anti-HIV SMS and SPS.
Methods. SPS including dextran sulfates (DS) of various mw, heparin, heparin sulfate, chondriotin sulfate (shark and bovine) pentosan polysulfate, Fucoidin, and carrageenan as well as SMS including D-glucosamine 2 sulfate, D-glucosamine 6 sulfate, D-glucosamine 2,6 disulfate and inositol hexasulfate were examined for their direct inhibitory effects on HIV-1 reverse transcriptase, syncytia formation (SF), and infection of preincubated target cells as well as on partial thromboplastin and prothrombin times.
Results. (1) All of the SPS inhibited HIV reverse transcriptase (25-99%) at 50 μg/ml of the SMS, only glucosamine 6 sulfate had significant anti-RT activity (30%). (2) Syncytia formation was inhibited by as low as 6 μgm of DS, carrageenan, fucoidin and pentosan polysulfate. D-glucosamine 6 sulfate completely inhibited SF at 50 μg/ml. Other SMS had no significant anti-HIV activity at this concentration. (3) All SPS had significant anticoagulant activity, whereas SMS had no anticoagulant activity up to 1 mg/ml concentration except inositole hexasulfate.
Conclusion. SPS have broader and more consistent anti-HIV activity but potential low TI because of anticoagulant activity. SMS, particularly glucose 6 sulfate, have higher *in vitro* TI and deserve clinical trial.

C.613

BLOCKING OF HIV-1 BINDING SITE BY LECTINS

Bagasra, Omar ; Heine., B. ; Whittle, P. ; Lischner, H.W. University of Medicine and Dentistry of New Jersey -SOM, Camden, NJ, USA. **Temple Univ., Philadelphia, PA, USA.

Objective. Blockade of the interaction of HIV-1 gp120 molecule with CD4-ligands is one of the many stratagems for blocking HIV-1 infection and possibly cytopathicity. The use of purified lectins, which are specific for one or two sugars, as a blocking agent may provide a rather simple way of HIV-neutralization.
Methods. (1) Sup-T, cells (CD4+ cell line) were pre-incubated with various lectins, washed, and degree of inhibition of FITC-CD4-ligands (OKT4A, OKT4F, Leu-3a) were evaluated by flow-cytometry and microscopy. (2) Anti-HIV activation of various lectins was examined by a sycytia-inhibition assay using Sup-T_1 and H9/III_B cells (J Infec. Dis). (3) Western blot analysis were performed to determine the possible site of binding of the lectins.
Results. (1) Five lectins; VVA, HPA, HAA, WFA and SBA completely or partially blocked the binding sites of HIV-1. (2) VVA, HPA, HAA, WFA, PWA, PHA, ConA, PSA and PNA blocked syncytia formation. (3) Western blot analysis revealed that two lectins, VVA and PSA have affinity for certain components of HIV-1.
Conclusion. (1) Lectins have specificity for a certain sugar or oligosaccharide. Therefore, they can be used as a mapping agent(s) for "anti-epitope" which will bind the "critical" HIV-CD4 site. (2) Theoretically, such sugars can be used to block HIV-1 from binding to CD4 and has therapeutic potential.

C.617

THE DEVELOPMENT OF NEW DRUGS TO TREAT HIV INFECTION: THE ROLE OF GOVERNMENT AND PRIVATE SECTOR INSTITUTIONS

Roland, Michelle* and Schmidt, R.M.**. Center for Preventive Medicine and Health Research. *San Francisco State University and *Pacific Presbyterian Medical Center, San Francisco, California, USA

Objective. To examine the role of government and the private sector in the development of new drugs to treat HIV-associated infections and cancers.
Methods. We reviewed: the organization and function of the U.S. Public Health Service (PHS), funding mechanisms for PHS agencies responsible for AIDS, implementation of AIDS drug research programs, number of drugs identified as potentially effective, results of clinical trials, number and characteristics of AIDS patients involved in new drug trials, the roles of academia and industry.
Results. The 3 agencies most directly involved in development of new AIDS drugs are the NCI, responsible for pre-clinical screening of drugs for anti-HIV activity; the NIAID, designs and funds clinical trials of proposed drugs; and the FDA, approves new drugs after safety and effectiveness have been established. Few children with AIDS (62 of 1134 in Sept 1988) and a low percentage of women and IV drug users with AIDS have participated in NIAID-sponsored drug trials. Despite some "pro-active" measures to expedite the review of AIDS drugs, the FDA causes significant delays in the approval process.
Conclusion. We recommend that community-based clinical trials would provide access to new AIDS drugs for a much larger population, and would have the advantages associated with a more personal physician-patient relationship. The NIAID announced such an approach on 22 November 1988. Community support is vital to the successful development of new AIDS drugs and vaccine development. Leadership at the Presidential level is required to solve the funding, staffing and administrative difficulties which continue in our national AIDS program.

C.618

FACTORS AFFECTING PARTICIPANT COMPLIANCE WITH ZIDOVUDINE CLINICAL TRIAL PO19

Cooke, M.; and McKusick, Leon.
Department of Medicine, Center for AIDS Prevention Studies, University of California San Francisco, USA.

Objective. To determine what factors correlate with adherence or non-adherence to protocol PO19 of zidovudine, so that recommendations can be made regarding the structure of AIDS clinical trials.
Methods. 50 adherents and 50 dropouts from the San Francisco sites of clinical trial PO19 were interviewed and administered questionnaires. In conjunction with medical records, additional data was gathered on two sets of factors: 1) Patient factors; Social support, sources of clinical trial information, psychological and somatic symptoms, perceived drug efficacy, personal efficacy, perceived threat of AIDS deterioration, alcohol and recreational drug use, and perceived AIDS loss in the participant social network; and 2) Study site perception factors; patient evaluations of study site structure and procedures, knowledge and attitudes about placebo, and attitudes toward researchers. Continuing volunteers were then compared with dropout on the above variables.
Results. Patient factors as well as study site factors were found to relate to adherence or non-adherence with PO19. Adherents were more likely to report social support for being in a clinical trial. Continuing participants and dropouts were nearly universally opposed to the use of placebo dose.
Conclusion. Dropout rate from AIDS clinical trials may be influenced by increasing the rigor of screening procedures on psychosocial and behavioral criteria: and by more thoroughgoing patient orientation and the need for placebo.

C.619

DISULFIRAM AS AN IMMUNOMODULATING AGENT - FOLLOW UP.

Bernard Bihari*,**; T. Fleischer**; J. Devine**; J.D. Seeman**; and Participating Physicians of the Community Research Initiative (CRI) *SUNY/HSCB, **CRI, New York, NY., U.S.A.

Objectives. To describe the results of an expanded trial of disulfiram in AIDS/ARC patients of CRI community physicians.
Methods. We initially monitored 53 AIDS/ARC patients who were taking disulfiram. Results of that monitoring included 1) significant increases in CD4 cells, 2) reduction of clinical symptoms, and 3) mild, reversible GI disturbance. We have continued our monitoring—and have increased the number of participants—following the same protocol: most individuals were treated with disulfiram 500mg p.o. twice weekly (some were prescribed 750mg p.o. once weekly); laboratory and clinical data were obtained on average every three months.
Results. The pooled data continue to show a considerable rise in T-helper cells and reduction in clinical symptoms. Abdominal cramps and/or diarrhea continue to be the most frequent side effects occurring in approximately 20% of our sample. A metallic taste has been infrequently reported.
Conclusion. Disulfiram continues to show promise as an immunomodulator. Our results suggest that large-scale, controlled clinical trials are warranted to test this hypothesis, which is based on preliminary findings in an open study.
Note: The CRI, while collecting data from community physicians who are prescribing disulfiram, does not itself endorse the use of any given product.

C.620

SYNERGISM AND POTENTIATION EFFECT OF A COMBINATION OF DIFFERENT DRUGS, DIRECTED TOWARDS VARIOUS STAGES OF THE VIRUS LIFE CYCLE, IN THE TREATMENT OF AIDS

Sarin, Prem S.*; Sun, D.K.*; Pontani, D.**; Thornton, A.*; Fullen, J.*; Shahied, S.I.**
*Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Md
**New Jersey State Department of Health, Trenton, NJ, U.S.A.

A number of antiviral agents that inhibit human immunodeficiency virus (HIV-1) in cell culture (MOLT-3, H9) have shown unacceptable levels of toxicity in human clinical trials. We have evaluated a number of drugs, including AZT, DDC, foscarnet and amphotericin methyl ester (AME), at levels much lower than traditionally employed to inhibit HIV replication. In our studies, we find that a significant potentiation/synergistic effect is observed when AZT, DDC or foscarnet are mixed with AME at approximately one-tenth the dose level required for complete inhibition of HIV replication by a single agent alone. Similar results have been obtained when antisense oligonucleotides directed towards two different target sites on the HIV genome are used in combination. These studies suggest that combination therapy using inhibitors of different stages of the virus life cycle may be beneficial in the treatment of AIDS.

C.621

ANTI-HIV ACTIVITY OF DEXTRAN SULFATE AS DETERMINED UNDER DIFFERENT EXPERIMENTAL CONDITIONS

Hideki NAKASHIMA[1,2], O. YOSHIDA[1], M. BABA[2], E. DE CLERCQ[2] and N. YAMAMOTO[1]
[1]Department of Virology and Parasitology, Yamaguchi University School of Medicine, 1144 Kogushi, Ube, Yamaguchi 755, Japan and [2]Rega Institute for Medical Research, K.U.Leuven, B-3000 Leuven, Belgium

Dextran sulfate is a potent and selective inhibitor of HIV-1. Its anti-HIV-1 activity has been investigated under varying experimental conditions. MT-4 cells were infected with HIV-1 at different multiplicities of infection (m.o.i.), and treated with either dextran sulfate, 3'-azido-2',3'-dideoxythymidine (AZT) or anti-HIV-1 serum (obtained from an ARC patient). Dextran sulfate suppressed HIV-1 replication (as monitored by viral antigen expression) when the m.o.i. was 0.01 or 0.1. It was ineffective at a m.o.i. of 1.0. The anti-HIV-1 serum was only partially effective at a m.o.i. of 0.01 and ineffective at a m.o.i. of 0.1 or 1.0. AZT proved effective at all three m.o.i.'s. Cocultures of uninfected and HIV-1-infected MT-4 cells were protected against destruction by dextran sulfate at a concentration of 10 and 100 μg/ml. A 1-hr contact of dextran sulfate (100 μg/ml) with the cells during the virus adsorption period sufficed to suppress HIV-1 antigen expression. In this sense, dextran sulfate behaved like anti-HIV-1 serum. Dextran sulfate also behaved like OKT-4A in that they both inhibited HIV-1 attachment to the MT-4 cells, whereas OKT-4 failed to do so. However, dextran sulfate did not affect the binding of OKT-4A to the cells. The present results support the concept that dextran sulfate owes its anti-HIV-1 activity mainly to inhibition of virus binding to its target cells.

C.622

AN HIV-1 P24 SCREENING ASSAY FOR DETECTION OF HIV-1 INHIBITORS

Corrigan, Alice L.; Kilkuskie, R.E.; Kaushal, I.A.; Adams-MacKie, B.A.; Youmans, M.G. and Bodner, A.J.
Biotech Research Laboratories, Inc., Rockville, MD 20850, USA.

Objective. To validate a sensitive, rapid, and reproducible screening assay for HIV-1 inhibitors.
Methods. H9 lymphocytes are treated for 1 hour at 37° C with an aliquot of a frozen stock of HIV-1 virions at a multiplicity of infection of 0.3 $TCID_{50}$/cell. The infected cultures are washed 3 times to remove unadsorbed virions. Test materials are titrated into both infected and uninfected H9 lymphocytes. After 3 days of incubation at 37° C, the cultures are centrifuged and the supernatants lysed for p24 antigen capture. The antigen capture assay uses a p24 specific, high affinity monoclonal antibody for capture of p24 onto microelisa plates and rabbit sera raised against affinity purified p24 as the detector antibody. Untreated, infected cell supernatants are titrated to the linear range of the capture assay standard curve. The p24 in a dilution of each test supernatant is determined and compared to that in the infected control cultures receiving no test compound to determine antiviral activity. The cell count of each uninfected test culture is compared to that in the uninfected control cultures to determine drug cytotoxicity.
Results. Infectious center assays have shown that 10% of the cells in the culture initially receive an infectious virion. Our antigen capture assay has readily detected virions released after a 3 day incubation, which is long enough for reinfection (40% of the cells contain virions at 3 days). Compounds have been evaluated at different dilutions for cytotoxicity and effectiveness as an inhibitor of p24 release. Anti-HIV-1 activity of AZT, ddC, and PFA in this assay has compared favorably to that observed in CEM-SS syncytia inhibition assays done in our laboratory and to published values obtained from other methods. We are currently testing 50 compounds a week at 3 dilutions each. We have used this assay to guide fractionation from active natural product extracts through HPLC purified fractions.
Conclusion. A sensitive, rapid, and reproducible assay has been developed to screen for possible HIV-1 inhibitors.

C.623

IN VITRO EFFICACY OF THE POLYSULFATED POLYXYLAN HOE/BAY 946 IN HIV INFECTED HUMAN MONOCYTES/MACROPHAGES

von Briesen, H.*; Christoph Meichsner**; Andreesen, R.***; Rübsamen-Waigmann, H.*; Schlumberger, H.-D.****; Schrinner, E.**
* Georg-Speyer-Haus, Frankfurt, FRG, ** Hoechst AG, Frankfurt, FRG, *** Universitätsklinik Freiburg, Freiburg, FRG, **** Wuppertal-Elberfeld, FRG

Objective. To present data demonstrating the efficacy of xylan(-hydrogen-sulphate) disodium salt (HOE/BAY 946) in HIV infection of human monocytes/macrophages.
Methods. A system has been developed in which human monocytes/macrophages from the blood of healthy donors are cultured on hydrophobic membranes. Cells which have been infected in Teflon® bags in the presence or absence of HOE/BAY 946, are transferred to 24-well microplates and further cultured in the presence or absence of the drug.
Virus production by the monocytes/macrophages is measured by reverse transcriptase activity or by antigen assay.
Results. The data presented show that HOE/BAY 946 drastically reduces the infection of human monocytes/macrophages in vitro.
Conclusion. Due to the important, possibly central role of monocytes/macrophages in the pathogenesis of AIDS, it is essential to show that drugs with anti-HIV activity are also effective in these cells; the efficacy of HOE/BAY 946 in these culture systems is demonstrated.

C.624

INHIBITION OF HIV REVERSE TRANSCRIPTASE BY 4-QUINOLONES

Gurtler, L., Eberle, J., Deinhardt, F.
Max von Pettenkofer Institute, University of München, FRG

Objective. One way to decrease the HIV load in symptomatic patients is to reduce virus replication. We looked for chemical compounds to achieve this.

Material and Methods. Ofloxacin, ciprofloxacin and norfloxacin were used at concentrations of 1 to 5 μM in 0.155 M sodium chloride, 0.01 M glycine-lactate buffer, pH 4.0. In a reverse transcriptase (RT) assay for HIV-1 using concentrated HIV-1, poly rAdT, and ^{3}H-TTP one fourth of the reaction volume was exchanged by the quinolones or appropriate controls, and inhibition of RT activity was measured up to 60 min.

Results. Complete inhibition of RT activity was observed at minimal concentrations of 3 μM ofloxacin and ciprofloxacin and 1 μM norfloxacin. The inhibition kinetics were linear over 60 min, and concentration dependent.

Conclusion. Chemical modification of currently available quinolone-derivatives could lead to substances valuable for clinical trials.

C.625

ENERGY CALCULATIONS ON ANTI-HIV NUCLEOSIDES: ENHANCED STABILITY OF C3'-EXO TWIST CONFORMATIONS IN ACTIVE COMPOUNDS

Ethan Will Taylor, B.B. Thompson, Patrick Van Roey* and C. K. Chu.
College of Pharmacy, The University of Georgia, Athens, GA 30602, and *The Medical Foundation of Buffalo, Inc., Buffalo, NY, U.S.A.

We recently reported (Taylor et al., 1989 ACS Abstr., Dallas) that for AZT and 2 other azide analogs, low energy conformers predicted by molecular mechanics (MM) correlate well with the observed crystal structures. The preferred conformations for the furanose ring in these azide analogs are C3'-exo ($_3T^2$ and $_3T^4$); this conformational preference may be a partial basis for the activity of these compounds. We report here the results of theoretical (MM) studies on the C3'-exo vs. C3'-endo preference for the same set of active and inactive compounds studied by Van Roey et al. (see the companion abstract).
Methods: Using MM (TRIPOS force field with COSMIC azide parameters), we have calculated the energies of both C3'-exo and C3'-endo ($^3T_2$) conformations, with optimization of all other conformational parameters (glycosidic angle, etc.), and compared the relative energies of the 2 forms.
Results: The 3 azide analogs (all active) show a preference for C3'-exo over endo of about 1.5 kcal/mole. The dideoxy analogs generally show a preference for C3'-exo (~1 kcal/mole over endo), although this difference is smaller (0.4 kcal/mole) for ddT and the inactive ddU. For other inactive compounds, including 3'-allyl-ddU and 3'-CN-dT, the C3'-endo form is preferred by at least 1 kcal/mole. For thymidine itself, the energy differences are negligible.
Conclusions: The calculations suggest that for good anti-HIV activity, the C3'-exo form should be at least as or more stable than the C3'-endo form. These results also correlate reasonably well with the X-ray observations. The possible electronic stabilization of the $_3T^4$ conformation by the azide rotating to a position underneath the furanose ring will be discussed.

C.626

Mechanisms of the anti-retroviral activity of aromatic polycyclic diones hypericin and pseudohypericin.

Daniel Meruelo, and Gad Lavie,
Dept. of Pathology, New York University School of Medicine, New York, N.Y. U.S.A.

We have recently reported that the polycyclic aromatic dione compounds hypericin (HY) and pseudohypericin (PS) inhibit the replication and infection cycles of a variety of murine retroviruses. These studies have now been extended to include the human HIV.

If a murine leukemia cell line (AQR) infected with and producing Radiation leukemia virus (RadLV), is incubated with hypericin, no detectable reverse transcriptase (RT) positive viruses are detected in the growth medium. This failure to produce RT positive virions is not the result of failure to produce viral mRNA or viral proteins within the infected cells. Rather assembly and/or processing of virions is affected by hypericin. Incubation of intact virus preparations with HY or PS also results in the inactivation of virion-derived reverse transcriptase activity and loss of infectivity of the particles. In all cases hypericin is a more potent antiretroviral agent than pseudohypericin. Clearly, the additional methyl group substitution in HY is important for antiretroviral activity.

C.627

BACULOVIRUS DIRECTED CELL-SURFACE EXPRESSION AND PURIFICATION OF CD4 IN INSECT CELLS

Webb, Nancy R.*; Madoulet, C.*; Tosi, P.F.**; Broussard, D.R.*; Saeed, L.*; Summers, M.D.*, Nicolau, C.*.
*Texas A&M University, College Station, Texas, USA, **Biopher Corporation, College Station, Texas, USA, and Baylor College of Medicine, Houston, Texas, USA.

Infection by the human immunodeficiency virus (HIV), the causative agent of acquired immune deficiency syndrome (AIDS) is mediated by the binding of the viral envelope glycoprotein, gp120, to CD4, a glycoprotein expressed on the surface of HIV-susceptible cells, most notably T helper lymphocytes (Sattentau and Weiss, 1988). In a recent report, we described the stable insertion of CD4 derived from human lymphocytes into red blood cells and its interaction with HIV-1 and HIV-infected H9 cells (Nicolau et al., J. Cell Biochem.12B, 254, 1988). The potential use of a CD4-erythrocyte complex as a therapeutic agent for AIDS requires large amounts of CD4 which contains the hydrophobic membrane-spanning region. To do this, we have produced a baculovirus expression vector (Luckow and Summers, 1988) for the abundant production of full-length CD4 in insect cells. We show that the recombinant protein expressed on the surface of insect cells is chemically, immunologically and biologically similar to CD4 expressed in human cells.

C.628

ESSAIS CONTROLES EN DOUBLE INSU DU LF 1695 CHEZ DES PATIENTS VIH+

Livrozet, Jean-Michel * ; Crimet, D.** ; Kienzler, J.L. ** ; Touraine, F. *** ; Touraine, J.L. *.
* Pavillon P , Hôpital E. Herriot, Lyon, France ; ** Laboratoires Fournier, Dijon, France ; *** Hôpital Neurologique, Lyon, France.

Objectifs. Evaluer et comparer l'efficacité de 2 posologies d'un immunomodulateur, le LF 1695 (Lab. FOURNIER) parmi 38 patients au stade de LPG ou d'ARC.
Méthodes. Dans un essai croisé randomisé en double insu, 20 patients ont reçu 1 gélule quotidienne de 120 mg de LF 1695, 15 jours par mois pendant 3 mois, puis 1 gélule de placebo en continu les 3 mois suivants ; 18 patients ont reçu une gélule de placebo 15 jours sur 30 pendant 3 mois puis une gélule de 120 mg de LF 1695 en continu les 3 mois suivants.Une évaluation clinique et biologique (NF, CD3+, CD4+, CD8+) a été réalisée tous les 45 jours. A la fin du protocole randomisé, les patients ont été traités par placebo ou LF 1695 en continu ou en discontinu selon un arbre de décision (variation de +/- 20 % du nombre de CD4+ au cours de l'essai randomisé).
Résultats. La comparaison du nombre de lymphocytes CD4+ au cours de la phase initiale ne montre pas de différence significative entre le groupe séquentiel et le groupe placebo, seule une tendance s'est manifestée à la posologie séquentielle. En revanche, lors du protocole de suivi, le nombre de lymphocytes CD4+ est significativement augmenté parmi les patients traités en séquentiel (med = 480 à J0 et 635 à la dernière visite) par rapport aux patients traités en continu (med= 411 à J0 et 344 à la dernière visite), ou par rapport au placebo (med = 426 à J0 et 376 à la dernière visite).
Conclusion. Le LF 1695 à la dose de 120 mg par jour, 15 jours par mois, présente un intérêt thérapeutique. Il devra être confirmer dans un nouvel essai randomisé.

C.629

C.630

IN VITRO ANTI-HIV ACTIVITY OF A NEW CLASS OF POLYMERS.

Lemaitre, Marc•; Boyer, B.••,Roque, J-P.••; Lamaty, G.••; Montagnier, L.••• and Zerial, A.•.
•Rhône-Poulenc SANTE, Research Center, F-94403 Vitry-Cedex, ••Université des Sciences et techniques du Languedoc, 34060 Montpellier-Cedex, France, •••Institut Pasteur, Viral Oncology, Paris, France.

Objective : We have synthesized a new class of polymers and tested their ability to act as HIV inhibitors.
Methods : We have tested these compounds as HIV replication inhibitors in CEM clone 13 cells and in human peripheral blood lymphocytes (PBL). We have measured the reduction of cytopathic effect (CPE) induced by HIV-1 (LAV-bru strain) - MTT assay - and reduction of reverse transcriptase (RT) activity in supernatants.
Results : Two polymers PS and PC were active. The EC_{50} were 1-3 ugr/ml and 2.5-7 ugr/ml respectively in CEM (7 and 14 days after infection respectively) and the EC_{50} of PS was 6 ugr/ml in PBL. The CC_{50} were in all cases superior to 100 ugr/ml. Both products were active when added to the cells 2 h. post infection ; in these conditions the EC_{50} in CEM were 5 and 10 ugr/ml respectively for PS and PC. RT production in cell supernatant was inhibited at the same concentrations as CPE.
When injected i.v. in mices (1 dose), the LD_{50} were 2-10 mg/kg (PS) and superior to 50 mg/kg (PC). Daily i.v. injection of PC at 2 mg/kg for 5 days was well tolerated.
Conclusions : Our new compounds were active as in vitro HIV inhibitors at doses similar to those reported for clinically used compounds.

C.631

CELLULAR PHARMACOLOGY OF 3'-AZIDO-2'-3'-DIDEOXY-URIDINE (AzddU) IN HUMAN PRIMARY CELLS: EVIDENCE OF A NOVEL METABOLITE

Zhou, Z.[1], Schinazi, R.F.[2], Eriksson, B.F.H.[2], Chu, C.K.[3], Williams, G.[4], and Sommadossi, J.-P.[1]

Univ. of Alabama at Birmingham, Birmingham, AL[1], Veterans Admin. Med.Ctr., and Emory Univ. Sch. of Med., Atlanta, GA[2],Univ. of GA, Athens, GA[3], and Triton Biosciences, Inc., Alameda, CA, USA[4].

Objective. To investigate the cellular pharmacology of AzddU (CS-87) and 3'-azido-3'-deoxythymidine (AZT) in human bone marrow (BM) and peripheral blood mononuclear (PBM) cells.
Methods. Human PHA-stimulated PBM or BM cells (2 x 10^6 cells/ml) were exposed to 10 μM (^{3}H) AZT or (^{3}H) AzddU from 2 to 48 hrs. The 60% methanol-soluble fraction of the cell lysate was analyzed by HPLC using a Partisil 10-SAX column.
Results. Within 2 hrs AZT-MP accounted for the majority (87 to 92%) of intracellular metabolites in both PBM and BM cells and remained at steady-state levels for 48 hrs. AZT-DP and AZT-TP increased within 48 hrs to 0.3 and 0.1 pmoles/10^6 cells in PBM and BM cells, respectively. AzddU-MP accumulated at a slower rate reaching 5 to 10 fold lower levels compared to AZT-MP and represented approximately 55 to 65% of intracellular radioactivity in both PBM and BM cells at all times. AzddU-DP approximated similar concentrations compared to AZT-DP in both cell systems, while AzddU-TP had 5-10 fold lower levels than AZT-TP in PBM cells. In contrast to AZT, an unknown ^{3}H-labeled anabolite of AzddU eluted between AzddU-MP and -DP with a different retention time from AZT-MP and -DP in both cell systems. This AzddU anabolite increased over time and represented as much as 25% of intracellular radioactivity in BM cells following a 48 hr exposure. The anabolite was resistant to 5'-nucleotidase, but was a substrate for 5'-phosphodiesterase, yielding AzddU-MP. Incubation of [^{3}H]-AzddU and [^{14}C]glucose in BM cells produced a double-labeled peak with the same retention time as the anabolite, suggesting formation of a AzddU-5'-diphosphate-hexose.
Conclusions. The metabolism of AzddU to a AzddU-DP-hexose in primary human cells, especially in BM cells, may contribute to the decreased toxicity of this anti-HIV drug when compared to AZT.

C.632

IMMUNOSTIMULATORY EFFECTS OF BETA-CAROTENE ON T-CELL ACTIVATION MARKERS AND NK CELLS IN HIV INFECTED PATIENTS.

Watson, Ronald R.*, Garewal, H.S.*+, Ampel, N.M.*+, Prabhala, R.H.*+, Allen, V.*+, Dols, C.*+, Hicks, M.J.*, *et al.*
*University of Arizona, +Veterans Administration Medical Center, Tucson, Arizona, USA.

Objective. Study the effect of beta-carotene on lymphocytes from patients with AIDS, based on its immunostimulatory effects in normal subjects.
Methods. Eleven HIV infected patients were given 30 mg/day of beta carotene for 4 months. Samples of heparinized peripheral blood were collected prior to, during, and after cessation of supplementation. Changes in the number and percentage of mononuclear cells with various markers were measured with monoclonal antibodies and flow cytometry.
Results. After 3 months of treatment the percentage of cells with markers of NK cells increased significantly (from 3.3 ± 2.8% to 19.4 ± 13.6%) in HIV infected patients. The percentage of cells expressing of IL-2R transferrin receptors, and HLA-Dr antigen was increased from 3.6 ± 48 to 16.8 ± 19.3; from 3.4 ± 3.1 to 29.2 ± 16.9; from 36.5 ± 9.5 to 61.1 ± 13.3 respectively by the treatment of beta-carotene for 3 months in HIV infected patients. No significant changes in T-helper, T-suppressor or total T-cells were observed during the treatment. Similar changes were seen in the numbers of these cells with each subtype. The maximum percentage was reached after 3 months, and had decline some by 4 months of treatment. These results are all qualitatively similar to those previously observed by us in normal subjects. No toxicity attributable to the drug was observed and the effects of cessation of supplementation were also assessed.
Conclusion. Beta-carotene produces an increase in the number of cells with NK markers and markers of activation (IL-2R, transferrin receptors). Clinical studies are warranted to assess if these findings will be of clinical benefit in AIDS or ARC patients. Supported in part by grants from Wallace Genetics and NIH AA-08037.

C.633

REDUCTION OF p24 ANTIGEN IN CDC II/III CASES WITH BD ZIDOVUDINE AND PROGRESSION TO AIDS

Tang A L, Gill S, Thin R N, Bateman N T, Cordery M, Barlow D.
St Thomas' Hospital, England.

Objective: To study the effect of 1200 and 800 mg Zidovudine given in 6 hrly or 12 hrly dosage on p24 antigenaemia in CDC II/III) patients.

Methods: 36 asymptomatic patients (CDC II/III) with p24 antigenaemia were randomised to receive either Zidovudine or Placebo on a double-blind basis. The results of the first 18 are shown.

Table 1	No of patients	Weeks 1-6	Weeks 7-12
A Zidovudine	7	600 mg bd	400 mg bd
B Zidovudine	5	300 mg qds	200 mg qds
C Placebo	3	6 caps bd	4 caps qds
D Placebo	3	3 caps qds	2 caps qds

Mean age was 35 years, average Hb at entry 14.5 g/dl (range 11.8-17.0) and median T4 cell count 0.50 x 10^9/1 (range 0.20-0.95).

Results: The mean percentage reduction of p24 antigen level was 62% (range 7-79%) in group A, 38% (range 0.87%) in group B and 0% in the Placebo groups. Mean percentage reduction of p24 antigen in the combined treatment group was statistically significant (p=0.01, Mann-Whitney U test), with no difference between groups A and B. Treatment was well tolerated apart from 2 Zidovudine treated patients who required transfusion. Patients were followed up for a minimum of 9 months after cessation of therapy. 7 (5 treated, 2 placebo) have continued with Zidovudine 250 mg or 500 mg bd and remain well. 7 (5 treated, 2 Placebo) have progressed to AIDS or ARC. The remaining 4 patients remain well.

Conclusion: Short-term Zidovudine given 600 mg and 400 mg bd reduces p24 antigen levels but may not influence progression of disease.

C.634

PULMONARY FUNCTION IN INDIVIDUALS WITH AIDS RECEIVING AEROSOLIZED PENTAMIDINE (AP) FOR PNEUMOCYSTIS CARINII PNEUMONIA (PCP) PROPHYLAXIS.

Sonnabend, Joseph*; Fleischer, T.*; Holzemer, S.*; Blau, A. *Community Research Initiative, New York., U.S.A.

Objective. To monitor pulmonary function in 205 patients with AIDS enrolled in a 1-year trial of two doses of AP for prophylaxis of PCP, which was fully enrolled by 6/28/88. 75.4% of study participants had experienced a prior episode of PCP.

Methods. Pulmonary function tests (PFTs) including measurements of DLCO, FEV, and FVC, were performed at entry, at 4-6 months, and at 12 months after entry. X-rays were obtained and physical examinations done at the same time.

Results. 125 patients were tested at entry and after 4-6 months (mean = 5.1 months). The mean values for FEV, and FVC did not differ at both times, nor were there significant differences in the distributions for both tests when the first repeat set of tests was compared to baseline. The DLCO, however, showed an increase in mean value on the second test; 73.2% (n=82) of the population showed an improvement in DLCO when retested after a mean period of 4.6 months on AP. The degree of improvement correlated inversely with the time elapsed since diagnosis of a prior episode of PCP. (r = -.214, p = .047).

Conclusion. No deterioration in pulmonary function could be shown in individuals with AIDS receiving AP (100 and 150mg biweekly) for a mean of 4.6 months. Whether AP hastens improvement in patients who have had PCP cannot be determined by this study.

C.635

DEXTRAN SULFATE DECREASES CELL SURFACE GP120, BUT DOES NOT INTERFERE WITH GP120 -CD4 INTERACTIONS

Callahan, L., Phelan, M. and Norcross, M.A.
Food and Drug Administration, Bethesda, MD. 20892 USA

Objective. Dextran sulfate has been reported to block virus binding to CD4+ cells . To determine if this effect is due to receptor blockage, we examined the effect of dextran sulfate on gp120 to CD4 binding and cell surface gp120 expression.

Methods. Gp120 binding to CD4 was measured by incubating recombinant gp120(Genentech) with Molt-4 T-cells followed by monoclonal anti-envelope antibody and fluorescently-labelled goat antibody to mouse Ig. Binding was also measured in an ELISA format by incubating soluble CD4(Biogen) with gp120 coated plates, developing with anti-CD4 monoclonals. The effect of dextran sulfate on cell surface expression of gp120 on H9 HIV-infected cells was quantitated by immunofluorescence and flow cytometry analysis.

Results. Anti-viral concentrations of dextran sulfate from 10ug/ml to 10 mg/ml were without significant effect on gp120-CD4 binding in both cell surface binding and ELISA assays. In contrast, HIV-1 chronically infected cells treated with dextran sulfate show marked decreases in gp120 surface staining, while CD3 remained constant.

Conclusion. Dextran sulfate does not directly block gp120-CD4 interactions. The rapid decrease in the amount of gp120 on the surface of infected cells suggests that the effects of dextran sulfate include the disruption of gp120 cell surface expression resulting in inhibition of syncytia formation.

C.636

Effect of amphotericin B and its methyl ester (AME) on human immunodeficiency virus infection and phagocytosis in macrophage cultures.

[1]D.R. Pontani, [2]D.K.L. Sun, [1]B. Wolf, [1]P. Bryant, [1]S.I. Shahied, [3]J. Brown, [4]J. Rosen, [5]O.J. Plescia, [5]C.P. Schaffner and [2]P.S. Sarin, U.S.A.

The polyene antibiotic amphotericin B and its methylated derivative AME were tested in the continuous macrophage cell line U937 for activity against HIV-1. At non-cytotoxic dose levels the expression of HIV-1 was inhibited as shown by the measurement of p24 antigen expression with immunofluorescence. At 10 ug/ml there was complete inhibition of virus activity.

To examine the effect of these drugs on the enhancement of monocyte activity, phagocytosis was measured using primary murine adherent cells. Either Sheep red blood cells, naked or coated with antibody, or Listeria monocytogenes were added to the cultures which had been incubated in the presence of each drug at concentrations of 0.1, 1, amd 10 ug/ml. Tuftsin was added as a positive control. With both systems a significant increase in phagocytic activity was observed in the presence of AME and amphotericin B.

These studies suggest that both AME and amphotericin B could be very useful in the treatment of AIDS due to their inhibition of HIV-1 replication in T cells and macrophages.

These compounds may provide an alternative to AIDS therapies due to their multifunctional cellular activities.

C.637

Effect of the polyene macrolide group of antibiotics on inhibition of Human Immunodeficiency Virus (HIV) replication in cell culture.

[1]Dennis R. Pontani, [1]S.I. Shahied, [1]Diane Zuberbuehler, [1]Gavin Swiatek, [2]Daisy K.L. Sun, [2]Prem S. Sarin

[1]New Jersey State Department of Health, Trenton, New Jersey
[2]Laboratory of Tumor Cell Biology, National Institutes of Health, Bethesda, Md. U.S.A.

The polyene macrolide family of antibiotics contain several potent antifungal compounds and act by binding to a sterol moiety in the membrace of cells. They have recently been shown to be effective inhibitors of HIV in vitro due to the presence of high cholesterol-phospholipid ratio in this virus. These antibiotics are grouped according to the number of conjugated double bonds in their lipophilic hydrocarbon region. A number of these compounds including the triene, tetraene, pentaene, hexaene and hepaene groups were examined for their cytotoxicity and activity against HIV. Of the compounds tested amphotericin B, its methylated derivative AME, nystatin and the methylated derivative of candicidin proved to be effective inhibitors of HIV-1 replication at non-cytotoxic dose levels. The other compounds tested were not active against HIV at non-cytotoxic dose levels. The results show the importance of structural modification as a means of reducing toxicity of parent compounds in the search for effective compounds for the treatment of AIDS. Current studies show that derivatives of amphotericin B are much less toxic compared to the parent compound without any loss of antiviral activity.

C.638

MECHANISTIC ASSAYS FOR NATURAL PRODUCT ANTI-HIV ACTIVITY

McMahon, James*; Weislow, O.**; Kiser, R.**; Gulakowski, R.* Warren, J.*; Gustafson, K.*; Bader, J.* and Boyd, M.*
*Developmental Therapeutics Program, DCT, NCI, **Program Resources, Inc., NCI-FCRF, Frederick, MD, USA.

Objective. To develop rapid quantitative microassays to study the mechanisms of action of compounds with anti-HIV activity isolated from natural products.

Methods. Microculture procedures were utilized to define the various stages of HIV infection in T-lymphoblastoid cells. Quantitative readouts of these assays included several novel colorimetric, enzymatic, and fluorometric endpoints. Interactive laser cytometry was also used to study the effects of anti-HIV compounds at the single cell level.

Results. In addition to developing quantitative tetrazolium and fluorometric assays for the overall cytopathic effects of HIV, microculture assays measuring the effects of compounds on virus/target cell interactions, reverse transcriptase and infectious viral release were also developed. Quantitative measurement of viral antigen expression at the single cell level was accomplished using immunocytofluorometric methods. Antiviral compounds with known mechanisms of action and comparative methodologies were used for assay validation.

Conclusion. Several rapid quantitative assays have been developed and/or modified which allow for the large-scale mechanistic screening and/or analysis of AIDS antiviral activity of natural products. These investigations attempt to determine where in the life cycle of HIV natural products exert their activity. Understanding the mechanisms of action of antiviral compounds will aid in the selection and prioritization of novel anti-HIV agents for clinical trials.

C.639

A TRIAL OF AEROSOLIZED PENTAMIDINE (AP) FOR PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP) IN AIDS.

Sonnabend, Joseph; Holzemer, S.; Fleischer, T.; Community Research Initiative, New York, U.S.A.

Objective. To investigate the safety of 100 and 150mg of AP delivered biweekly to individuals with AIDS, as well as the efficacy of these dosages in the prevention of PCP.
Methods. Eligible participants who had CDC-defined AIDS, were randomized to receive either 100 or 150mg of AP biweekly using the Marquest Respigard 2 nebulizer, in a 1-year trial fully enrolled by 6/28/88.
Results. 232 subjects were enrolled, for 198 of whom demographic data was available; 77.5% white, 5.3% black, 14.2% hispanic, 2.4% women. 63.9% had a prior episode of PCP (mean of 7.6 months before entry). 83.4% were gay/bisexual men, 6.5% intravenous drug users, 1.2% blood transfusion recipients. As of 1/89, 46% had discontinued participation (26.4% voluntary withdrawal, 35.8% non-compliance, 12.3% intercurrent illness, 25.5% death). AP was well tolerated with no significant side effects, and results of pulmonary function tests (FVC, DLCO, FEV_1) showed no deleterious effect after a mean of 4.6 months. The number of cases of proven PCP was far less than anticipated for this population.
Conclusion. AP (100 & 150mg biweekly) demonstrated no systemic or localized pulmonary toxicity. The recurrance rate of PCP in those who had experienced a prior episode appeared to be considerably lower than that anticipated for 2nd episode cases.

C.640

A CRITIQUE OF THE U.S. GOVERNMENT AIDS CLINICAL TRIAL PROGRAM

Long,Iris; Kirschenbaum, D.; and Huff, R. AIDS Coalition to Unleash Power, New York, New York, USA.

Objective. To evaluate accessibility of experimental treatments in the AIDS Clinical Trial Group (ACTG) Program to HIV-infected people.
Methods. In January 1989, this program had enrolled over 5,700 subjects in trials at 35 sites and 11 pediatric centers. Government documents related to these trials were reviewed periodically.
Results. There were 24 agents under study and 45 trials open. Twelve trials were closed and 2 completed. There were 12 AZT trials in which 4,625 subjects (80% of total program enrollment) were enrolled. AZT was being tested at many different stages of the disease. There were also 16 trials of AZT in combination with other drugs, with a total program enrollment of 7%. Antivirals other than AZT were in 12 preliminary Phase I or pharmokinetic trias and had enrolled 249 subjects (4% of total program enrollment). Enrollment by sex: Male 94.2%, female 5.8%. Enrollment by race: white 82.5%, black 6.9% and hispanic 8.9%. Enrollment by IV drug use history: never used 88.3%, previously used 11.03% and currently using 0.3%.
Conclusion. The main drug tested in the program is AZT alone or in combination. Access to trials testing other antivirals besides AZT or in combination with AZT is very limited. Women, people of color, children hemophiliacs and prisoners are not represented to the extent that they are HIV-infected. All recently diagnosed people with AIDS have few clinical trial options.

C.641

SPECIFIC INTERACTION OF AURINTRICARBOXYLIC ACID WITH THE HIV/CD4 RECEPTOR

Dominique SCHOLS, M. Baba, R. Pauwels, J. Desmyter and E. De Clercq
Rega Institute for Medical Research, K.U.Leuven, B-3000 Leuven, Belgium

Considering the essential role of the CD4 receptor in the replicative cycle of HIV, it would seem important to find appropriate marker molecules that specifically interact with the CD4 receptor and thereby block HIV attachment to the cells.

$CD4^+$ cells (MT4, U-937, peripheral blood lymphocytes and monocytes) were incubated in the presence or absence of the test compounds, stained with various monoclonal antibodies (mABs), washed, fixed and examined by flow cytometry. To investigate virus-cell binding, MT4 cells were exposed to radiolabeled HIV-1 virions in the presence or absence of the test compounds.

The triphenylmethane derivative aurintricarboxylic acid (ATA), but not aurin, selectively prevented the binding of OKT4A/Leu3a mABs, and, to a lesser extent, OKT4 mABs to the CD4 receptor of all four cell types at a concentration of 10 µM. The effect was rapid (1 minute), dose-dependent and reversible. It could be neutralized by serum. ATA also prevented the attachment of radiolabeled HIV-1 virions to MT-4 cells, presumably as the result of its specific binding to the CD4 receptor.

These unusual properties of a small molecule of non-immunological origin may have important implications for the study of CD4, HIV, AIDS pathogenesis, and, possibly, therapy and prophylaxis.

C.643

VARIABILITE DES SEQUENCES DU VIRUS DU SIDA

C. CHAPPEY[1], P. SONIGO[2], S. HAZOUT[1], A.-J. VALLERON[1]
[1] INSERM U263, [2] INSERM U163, Institut Pasteur, Paris, France

Objectif : La variabilité génétique du virus du SIDA peut être utilisée comme un outil d'analyse des protéines virales, justifiant donc une analyse quantitative détaillée. L'objectif de ce travail est, après avoir conclu statistiquement à la non-homogénéité du taux de substitution par site, de caractériser dans les séquences différents ensembles de régions de taux de substitution proche. Les données utilisées sont les séquences publiées de la protéine de l'enveloppe.
Methodes : A partir de l'alignement multiple des séquences HIV-1, HIV-2 et SIV, on construit d'abord une séquence consensus avec les acides aminés les plus fréquents à chaque site; on calcule ensuite le taux de substitutions par rapport au consensus le long de la séquence, ceci constituant la fonction de variabilité. Un ensemble de tests statistiques est effectué sur cette fonction afin de vérifier l'existence de régions homogènes.
Resultats : L'analyse statistique a permis de classer l'ensemble des régions en trois groupes de variabilité et de composition nucléotidique (en position 1 des codons) différentes.

Régions		hyper variable	variable	conservée	global
Longueur en Ac.Am.		33	336	449	818
Longueur (%)		4.0	41.9	54.7	100
Taux moyen (%) de substitutions par site		63	18	6	13
Taux en	bases A, G	55.2 - 33.7	40.0- 27.1	33.3 - 28.5	36.7 - 28.0
	bases T, C	8.3 - 2.8	18.7 -15.0	19.3 - 18.9	18.6 - 16.7

Le découpage de la séquence en régions ne se révèle significatif que pour des tailles inférieures à 15 résidus.
Conclusion : L'analyse des séquences à l'aide d'une telle partition constitue une étape nécessaire qui peut être discutée en termes de relation structure-fonction

C.644

C.645 DIFFERENCE IN LONG TERMINAL REPEAT ACTIVITY OF TWO HUMAN IMMUNODEFICIENCY VIRUS-1 VARIANTS FROM THE SAME PATIENT

Golub, Efim; Li, G. and Volsky, D.J.
Molecular Virology Lab, St. Luke's/Roosevelt Hosp. Ctr. and College of Physicians and Surgeons, Columbia University, New York, NY, U.S.A.

Objective. To compare transcriptional activity of long terminal repeats (LTR) of different HIV-1 variants.
Methods. LTR activity was analyzed by transient chloramphenicol acetyltransferase expression assay or by measuring production of p24 protein.
Results. Two HIV-1 variants, derived from a single parental isolate and termed N1T-E and N1T-A, differ substantially in their ability to replicate in CD4-positive cells. We show that the LTR of the better-replicating N1T-E virus has a 3-5 fold higher capacity than N1T-A LTR to direct gene expression in T cells. The higher activity of N1T-E LTR is due to a combined effect of two mutations: i) a point mutation in position -94 (relative to the CAP site), which is located between the two subunits of HIV-1 enhancer; ii) a duplication of 24 base pairs in positions -128 to -152, which has not been known to be involved in any regulatory function. Presence of these mutations increases the basal level of the LTR-driven gene expression and does not influence the degree of induction caused by the viral tat gene product or by cell activation.
Conclusion. HIV-1 LTR is one of the sites which may determine functional heterogeneity of HIV-1.

C.646 DELAYED & SLOW EXPRESSION OF HIV-1 RNA & tat PROTEIN DURING INFECTION WITH A NON-CYTOPATHIC HIV-1 VIRUS

Sakai, Koji; Ma, X-Y; Sinangil, F. and Volsky, D.J.
St. Luke's/ Roosevelt Hospital Center and College of Physicians and Surgeons, Columbia University, New York City, NY, U.S.A.

Objective: To study the mechanism of infection with a non-cytopathic isolate of HIV-1.
Methods: The non-cytopathic and cytopathic HIV-1 isolates N1T-E and N1T-A, respectively, were obtained from the virus-producer CEM/HIV-1/N1T cell line by molecular cloning. Virus entry was measured as a function of the virus-cell fusion by the membrane fluorescence dequenching assay. Viral RNA was detected in crude cell lysates with ^{32}P-RNA probe from the pol gene. tat and rev proteins, and LTR functions, were tested by CAT assay.
Results: N1T-E and N1T-A entered CD4-positive target cells with equal efficiency by virus-cell fusion. The expression of N1T-E genome was delayed and characterized by slow kinetics, resulting in low levels of N1T-E RNA, structural proteins, and tat protein during the first 7-10 days after virus entry. In contrast, cells infected with the same dose of the cytopathic N1T-A virus began to express high levels of HIV-1 RNA structural proteins and tat protein activity within 48 hours of infection; the expression peaked on day 5, followed by complete cell lysis. Both N1T-E and N1T-A viruses replicated well in chronically-infected cells.
Conclusion: Our results show that slow kinetics of HIV-1 expression during early stages after virus entry is an important determinant in a non-cytopathic infection.

C.647 EXPRESSION OF gag PROTEINS OF HUMAN IMMUNODEFICIENCY VIRUS USING RECOMBINANT ADENOVIRUS VECTORS

Katherine L. Molnar-Kimber, Robert Mastroeni, Surendra K. Dheer, Robert Natuk, Bheem Bhat, Pranab Chanda, Satoshi Mizutani, Alan R. Davis and Paul P. Hung. Biotechnology and Microbiology Division, Wyeth-Ayerst Research, P.O. Box 8299, Philadelphia, PA USA 19101-1245.

To develop Ad4-HIV recombinant adenovirus type 4 vaccine candidates, the gag-pol gene of Human Immunodeficiency Virus was inserted into the Ad4 E3 region. In attempts to generate a new late transcription family, an oligomer which contained 32 bp of the splice acceptor from the L5 transcription family was inserted upstream of the gag-pol gene followed by a large E3 deletion and an intact E3B polyadenylation signal. The recombinant adenovirus, WyAd4FSACHgag synthesized gag p55 protein both early and late during infection. Although the protease gene was intact, no protease activity was detectable. The expression of the gag proteins was approximately 50X lower than expression of the hepatitis B virus envelope proteins using Ad4 E3-based vectors. Recent reports suggest that the expression of the gag-pol proteins is positively regulated by the presence of rev. The mechanism will be discussed.

C.648 PURIFICATION OF RECOMBINANT HIV PROTEINS BY ISOELECTRIC FOCUSING.

Chen, Albert*, Winslow, E.*, Stafford, A.*, Sass, J.*, Siaw, M.*, Van Winkle, M* et al.**. *Beckman Instruments, Inc., Irvine, CA 92714, and **SmithKline Beckman, King of Prussia, PA. U.S.A.

A preparative isoelectric focusing (IEF) method using a commercially available apparatus was applied to the purification of recombinant HIV proteins expressed in E. coli. Proteins representing env, gag and pol domains were extracted from inclusion bodies and initially purified through varying sequences of ion-exchange and molecular sieving chromatography. Proteins obtained from the primary purification were desalted and subjected to isoelectric focusing separation. Appropriately solubilized proteins in the presence of various non-ionic surfactants and ampholytes were focused and concentrated at their isoelectric points (pI). Proteins were harvested in fractions after reaching equilibrium. Each fraction was analyzed electrophoretically for purity and further identified by western blot using specific monoclonal antibodies. The results of ELISA testing for HIV antibodies using the IEF proteins showed significantly increased activity and specificity. Our work shows that IEF methodology can yield significant quantities of effectively purified recombinant proteins in a simple, efficient and cost effective process.

C.649 CONSTRUCTION OF HIV-1 INTER-ISOLATE RECOMBINANTS

York, D.*; Borissenko, L.*; Bauer, D.*; Cheng-Mayer, Cecilia**; Levy, J.**; Dina, D.*.
*Chiron Corporation, Emeryville, CA., USA, **University of California- San Francisco, San Francisco, CA., USA.

Objective. Construction of inter-isolate recombinant HIV-1 viruses using molecularly cloned DNA from viruses with distinct biological properties was undertaken to identify the genes determining those specific biological properties.
Methods. The HIV-1 isolates SF-2 and SF-33 differ biologically in their ability to form plaques in the MT-4 cell line (possibly related to their cytopathicity) and their host range. The SF-2 isolate replicates in peripheral blood lymphocytes and CD4+ established T-cell lines such as HUT 78 and CEM, whereas the SF-33 isolate additionally replicates in human and baboon peripheral mononuclear cells as well as human fibroblasts such as HOS. By making constructs exchanging specific regions between the two molecularly cloned HIV-1 genomes, it should be possible to follow the biologic characteristics. The construction series was transfected into cells and infectious virus was rescued from all combinations for comparison studies.
Results. Biologic assays performed on the recombinant viruses indicate that plaquing in MT-4 cells and cytopathicity segregate with the env-3'orf region of the genome. Host range specificity is being examined.
Conclusion. The env-3'orf region of the HIV genome appears to be directly responsible for the cytopathicity characteristic of the isolate.

C.650 NO PRIMARY DETECTION OF HIV AMPLIFIED DNA SEQUENCES IN URINE SEDIMENTS OF SEROPOSITIVE INDIVIDUALS.

Gasparini P*, Mezzelani Paolo**, Savoia A*, Pignatti PF*, Morandi C*, Venturini L** and De Sandre G**.
* Institute of Biological Sciences - University of Verona - Italy
** Institute of "Patologia Speciale Medica" - University of Verona -Italy

Objective. To validate the data on urine infectivity in seropositive individuals, searching HIV DNA by "polymerase chain reaction" (PCR) technique in their urine sediments.
Methods. We collected 50 ml urine and 20 ml peripheral blood from five HIV seropositive drug addicts. The cell pellet was resuspended in 500 ul water and boiled for 10 min. Cell debris were eliminated by centrifugation and the clear supernatants were directly used for the PCR. Primers pair from the gag region of the HIV genome were used to achieve maximum sensitivity of provirus detection. The reaction was carried out, for 30 cycles, in 1x Taq DNA polymerase buffer, 20 nmol dNTP mix, 50 pmol of each oligonucleotide primer made up to 100 ul with distilled water and 5.0 U of Taq polymerase. Control reactions were run with two other primers which amplified the polymorphic region of the CS.7 probe, a marker tightly linked to the Cystic Fibrosis gene. The amplified viral DNA was detected on a dot-blot, with a P32-labeled DNA probe. In the case of the CS7 control amplification, the DNA fragments were visualized after gel electrophoresis.
Results. HIV sequences were detected in peripheral blood specimens from seropositive persons, but not in their urine. Control seronegative samples proved, as expected, negative both in the blood and urine samples. On the contrary, positive direct DNA amplification of the CS.7 region was obtained from each sample of the urine, confirming the feasibility of this physiological liquid as a source of material for PCR analysis.
Conclusions. The absence of proviral amplified sequencies in all urine sediments, in the presence of HIV amplification in the blood, and of CS.7 amplification in the urine, is in accord with the report of the very low probability of viral presence in the urine, and with the lack of epidemiological evidence of infection through this body fluid. Our results confirm the potential utility of the PCR technique in complementing or replacing virus isolation procedures as a routine means of determining the presence of HIV in blood cells.

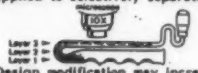
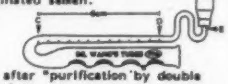
HIV/STD-CONTAMINATED HUMAN SPERM MOTILITY; DIAGNOSIS AND "EXPERIMENTAL ISOLATION OF SPERM USING "SWIM UP" TECHNIQUE IN WANG'S TUBE AND COMPUTERIZED IMAGE ANALYSIS

Fu-Nan Wang*, C.M. Cheng, E.S.E. Hafez
Microbofre Scientific Institute, Republic of China*, World Federation of Contraception/Health & Reproductive Health Center, Kiawah, SC, U.S.A.

The human semen contains high titers of HIV/STD's. Little is known about the mechanisms of the life cycle of HIV in semen heterosexual transmission and its role in HIV particles, released from infected lymphocytes in the semen, blinds randomly is seminal plasma in HIV, attached to specific "domains" on the surface membrane of sperm, can penetrate specific segments of sperm head/midpiece computerized image analysis of sperm motility patterns may lead to early identification of HIV-STD's contaminated semen. HIV virons are attached to sperm surfaces, the physiological integrity of the membranes of the acrosome/mitochondrial sheath, are damaged leading to significant change in sperm motility patterns. Based on swim up concept, Wang's tube; originally designed to separate highly motile sperm for clinical use in artificial insemination and IVF, is applied to selectively separate HIV/STD's contaminated semen.





Design modification may increase sperm numbers after "purification by double assurance" during sperm migration within the device.
